
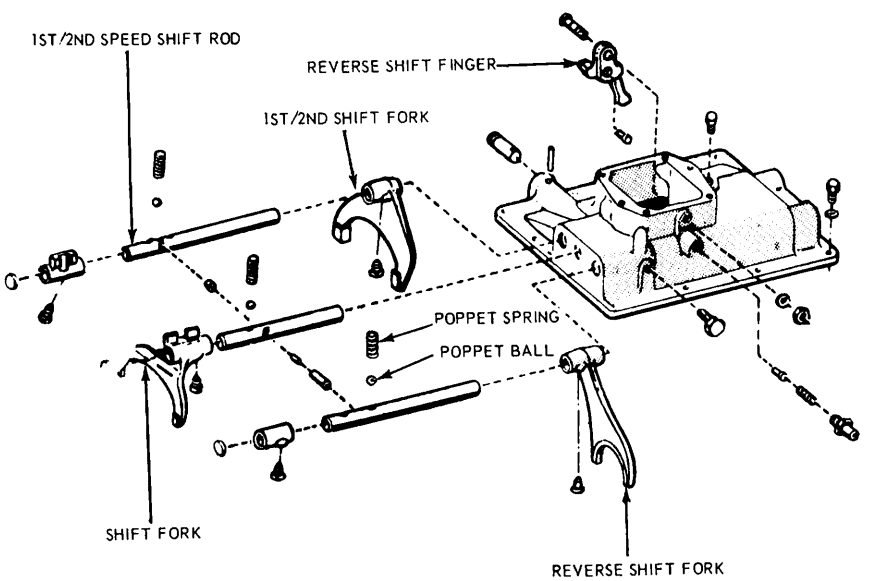
C 2155-A

FIG. 3 Transmission Rear Support Mounts



C 2303-A

FIG. 4 Front Unit Shifter Housing

DISASSEMBLY AND ASSEMBLY

MAIN TRANSMISSION

Refer to Auxiliary Transmission for instructions on separating the main and auxiliary sections of the transmission.

Disassembly

1. Lock the transmission in two gears by engaging third and fourth-speed clutch gear collar with drive gear, and reverse sliding gear with second-speed gear (Fig. 5).
2. See Fig. 6. Remove the capscrew and washer attaching the long clutch release shaft to the clutch release yoke.
3. Remove the key and tap the release shaft free of the yoke. Remove the shaft through the side of the clutch housing. It is not necessary to remove the clutch housing unless it is damaged.
4. Slide the yoke and the short shaft toward the inside of the housing and remove as a unit.
5. Remove the stud nuts (Fig. 7) and lock washers from the main drive gear bearing cap.
6. If the bearing cap oil seal is damaged, remove it with a drift.
7. Unstake the drive gear bearing nut from slots in the drive gear shaft. Use a suitable tool to remove the bearing nut from the main drive gear, **keeping in mind that the drive gear bearing nut has a left hand thread (Fig. 5).**
8. Support the outer race of the bearing and press the main drive gear out.
9. If the mainshaft pocket bearing remained in the drive gear, remove it.
10. Slide the third and fourth clutch collar from the clutch gear.
11. Remove the capscrews and washers from the retainer.
12. Remove the lock wire from the capscrews.
13. Remove the capscrews and lockplate from the pocket of the mainshaft rear drive gear (Fig. 5).
14. Use a suitable puller tool to remove the rear drive gear from the mainshaft splines.
15. Use a suitable wire or rope sling under the approximate center of the mainshaft gears, and remove the mainshaft and gears from the case.
16. Remove the reverse idler shaft lockplate by removing the lockplate capscrew and lock washer.
17. Using a long through bolt with 1 3/4 inch by 6 inch tubing and flat washer pull the reverse idler gear shaft out through the rear of the case.
18. Remove the reverse idler gear sub-assembly from the case as the idler shaft is pulled free (Fig. 8).
19. Remove the countershaft front bearing cap.
20. Remove the lock wire from the capscrews.
21. Remove the capscrews and the lockplate from the end of the shaft.
22. Using a suitable puller tool, or puller screws, remove the bearing retainer and taper bearings from the shaft.
23. Move the countershaft sub-assembly toward the rear of the case until the rear bearing is free of the case bore. Using a suitable puller, remove the bearing from the countershaft (Fig. 8).
24. With the countershaft free of the front bearings, lift the front end up first and remove the entire sub-assembly from the case.

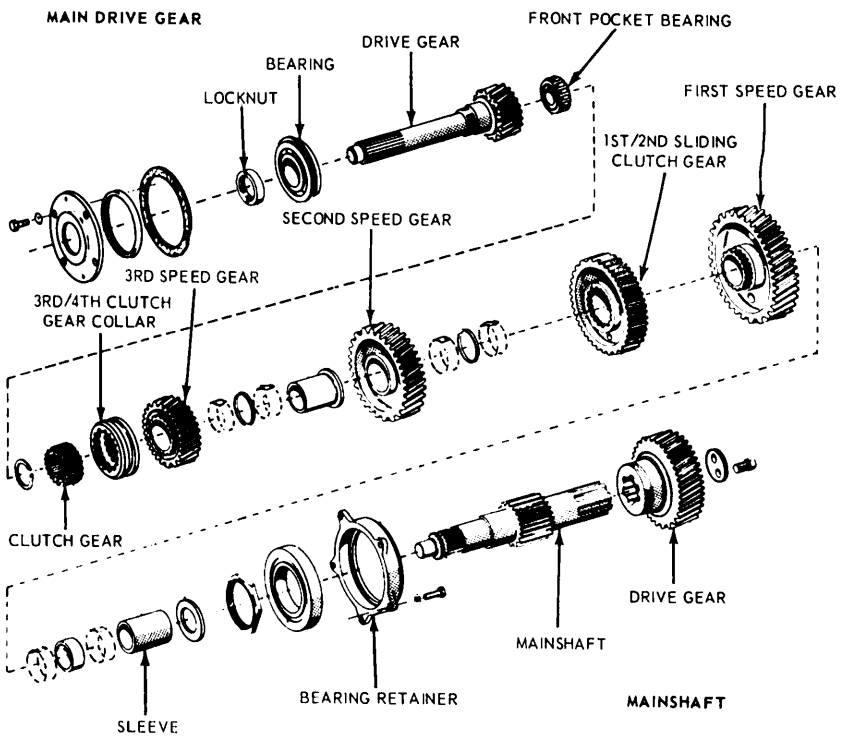


FIG. 5 Front Unit Drive Gear and Mainshaft

Assembly

1. Lower the countershaft assembly into the case with the rear end through the rear bearing retainer bore. Align the front end of the shaft with the front bearing retainer bore.
2. Assemble the tapered bearings and cones into the retainer. Place the gasket on the retainer and bearing sub-assembly.
3. Assemble the bearing retainer sub-assembly onto the end of the shaft, and press, or tap it into the case bore.

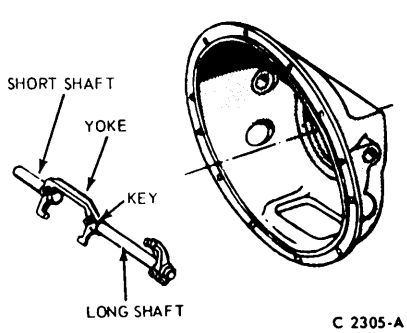

FIG. 6 Clutch Housing and Release Parts

4. Pull the front cup approximately 3/32 inch out of the retainer bore. Place the correct shim pack on the retainer to allow 0.003 to 0.008 inches countershaft end play movement. Holes in bearing retainer cap and shim pack are equally spaced except for one which is displaced 5 degrees to insure alignment of the oil return pocket. There is enough clearance in the shim pack, however, to allow it to be assembled backwards. When this occurs the threads of the screws engage the edge of the shim pack and pull metal into the screw holes as well as inflicting a wrinkle to the pack itself. It is suggested that the four capscrews be put through the bearing cap; then, place the shim pack on the capscrews. This will serve as a pre-assembly stacker and align the shims properly.
5. Secure the bearings on the shaft with the lockplate and capscrews. Torque the capscrews to 40-50 ft-lbs and secure with lock wire.
6. Assemble the front cap to the case and secure with capscrews and lock washers. Torque capscrews to 40-50 ft-lbs.
7. Position the rear bearing on the countershaft, external snap ring toward rear. Align shaft and bearing with case bore and, using tubing, drive against inner race until bearing is seated. **Use caution when installing bearing as improper alignment can cause severe brinelling to inner race and distortion to the rolls.**
8. Check countershaft end play, which should be .003-.008 before installing mainshaft into case.
9. Assemble the reverse idler gear key to the sleeve.
10. Assemble the gear to the sleeve and make sure the gear slides back and forth freely on the key. It should be noted that the sleeve has been ground to incorporate a hopping guard (to prevent walking out of reverse). The gear must be assembled to the sleeve with the shift fork collar toward the rear. The smaller OD end of the sleeve is stamped **front. If these letters are raised, or rough, they should be ground flush.**
11. Grease the two sets of roller bearings (Fig. 8) lightly and assemble to the bore of the sleeve.
12. Place the reverse idler assembly in the case, with thrust washers one at each end of the sleeve.
13. Insert the reverse idler gear shaft plain end first, through hole in rear of the case and into reverse idler bearings. Align **flat** on rear end of shaft for lockplate and tap into final position.
14. Assemble lockplate to case with capscrew and lock washer.
15. Position drive gear bearing under arbor with shield up. Support inner race of bearing and press drive gear into bearing.
16. Using soft jaws in vise, clamp on teeth of drive gear and assemble lock nut. This is a left hand thread. Tighten lock nut to 550-600 ft-lbs torque. Stake lock nut in two grooves provided on drive gear. If lock nut has a straight OD the bearing cap (with oil seal installed) must be assembled OVER THE DRIVE GEAR AND BEARING BEFORE ASSEMBLING AND TORQUING LOCK NUT. If lock nut has taper on the OD, the lock nut can be assembled and torqued on the drive gear and bearing. Then the bearing cap and seal can be assembled over the tapered OD lock nut without damage to the seal lip. Damage of the seal lip in bearing cap will cause oil leakage when transmission is assembled into the vehicle. Oil leakage could find its way up the drive gear stem and be thrown into the clutch facing of the clutch discs. This will cause clutch slippage, and eventual clutch and transmission damage.
17. Apply a light coat of gasket cement to sealing face of drive gear bearing cap. Most drive gear bearing caps

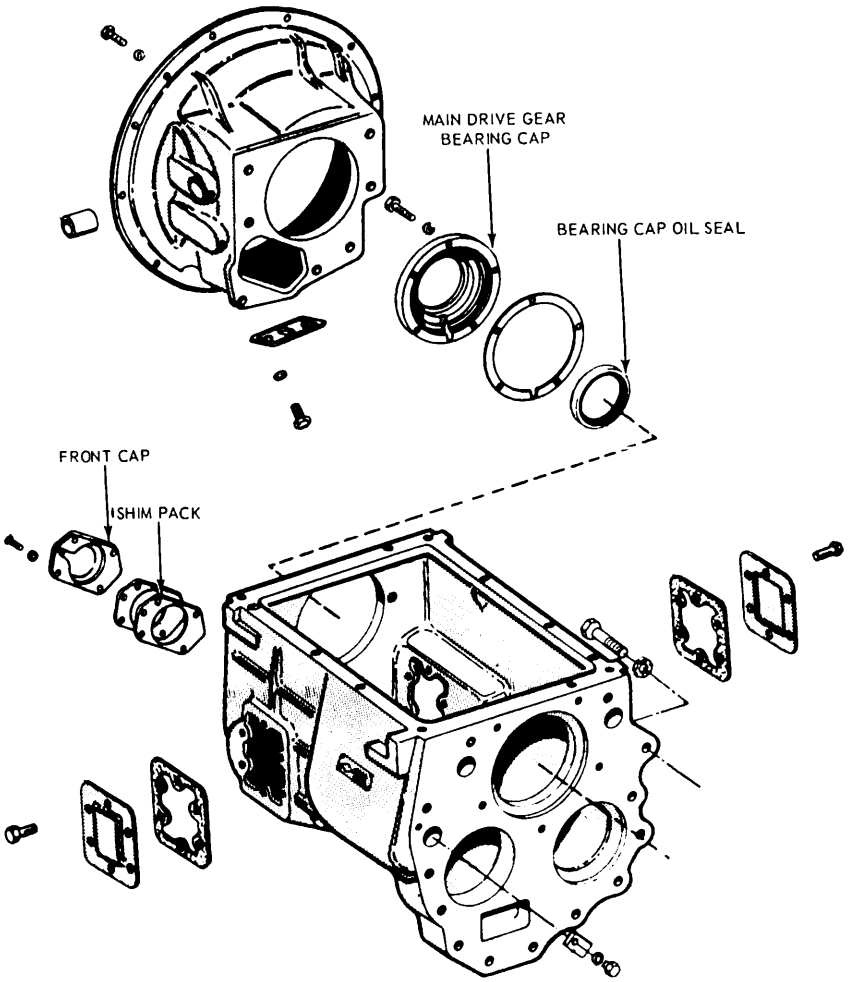

FIG. 7 Front End Disassembly

are marked TOP. **When the word TOP is up, the oil drain back hole should be at the 7 o'clock position.**

18. Assemble main drive gear and bearing cap sub-assembly to the front of the mainshaft. Roll mainshaft up with large screwdriver to align pocket bearing on mainshaft with bearing bore of drive gear.
19. Locate and secure bearing cap to main case with capscrews and lock washers. Torque capscrews to 25-28 ft-lbs.
20. Position the clutch housing on the case studs or retain with capscrews and lock washers.
21. Lower rear end of mainshaft assembly into case and out rear bore of case. Lower front of shaft into position and mesh mainshaft gears with countershaft gear.
22. Using a 13/16 inch thick flat steel stock for support block, insert stock between front of case and front of mainshaft. Lift entire case assembly onto press bed, with front of case down on bed. Keep mainshaft with gears centralized to the rear bore.
23. Place rear drive gear sub-assembly on output spline of shaft. Press onto splines, aligning bearings to rear bearing diameter, and locating holes of bearing retainer to holes in rear face of case.
24. Assemble capscrew and washers to bearing retainer and case. Torque capscrews 40-50 ft-lbs.
25. Assemble lockplate and capscrews to mainshaft. Torque capscrews to 60-80 ft-lbs. Secure with lock wire.
26. Remove entire case assembly from the press, and put assembly on floor, in vertical position for preparation of joining rear case assembly and front case assembly.
27. Rotate front drive gear to make sure all gears and shafts turn free.
28. Unlock transmission gears and make sure mainshaft rotates freely.
29. Assemble pocket bearing to end of mainshaft. Since pocket bearing fits tight on end of mainshaft, use tubing to drive against inner-race.
30. Install the short clutch release shaft (Fig. 7) and the release yoke through the side of the clutch housing.
31. Install the long clutch release shaft in the opposite side and assemble it to the yoke with key, capscrew, and lock washer.

MAIN TRANSMISSION SUB-ASSEMBLIES

MAINSHAFT

Disassembly

1. If the front pocket bearing remained on the mainshaft, remove it with a puller.
2. Unstake the drive gear bearing lock nut, and remove the lock nut (Fig. 5).
3. **Place the drive gear and bearing subassembly vertically in an Arbor Press with the front end up. Use two 1/4 inch thick plates to support under the bearing retainer and press the gear free of the bearing.**
4. Press the bearing retainer free of the bearing.
5. Remove the snap ring from the front end of the mainshaft.
6. Remove the clutch gear from the splines.
7. Remove the third-speed gear, being careful to retain the needle rollers with the gear.
8. Remove the third-speed gear sleeve from the shaft. If this requires more than normal force, use a puller behind the teeth of the second-speed gear and remove the gear and the sleeve from the shaft together. **When pulling the second-speed gear, use caution to retain the needle rollers or they may fall away from the gear when it is removed from the shaft.**
9. Remove the sliding gear from the shaft splines.
10. Remove the first-speed gear from the shaft with the needle rollers and the thrust washer.
11. If the sleeve is worn or damaged, it should be replaced.

Assembly

1. **Set mainshaft vertically in a vise with the front or pilot bearing diameter up. Protective vise jaws should be used to grip the diameter, and against the shoulder at end of the long splines. To fit new parts an Arbor Press may be required. If so, follow this same procedure. All needle bearing rollers and spacers should be assembled into the gear bores before assembly of gears onto the mainshaft. Use heavy grease in the gear bores to hold the needles in place. The needle bearings should not completely encircle the bore. Space for one needle should be left unfilled to allow for adequate lubrication and free movement of the bearings.**
2. With the bearings and spacer in the bore of the second-speed gear, assemble the gear to the mainshaft with the clutch teeth down or toward the splined center section.
3. With the needle bearings and the spacer in the bore of the third-speed gear, place the third gear sleeve into the gear needle bearing bore with flange end on the opposite end of the gear clutching teeth.

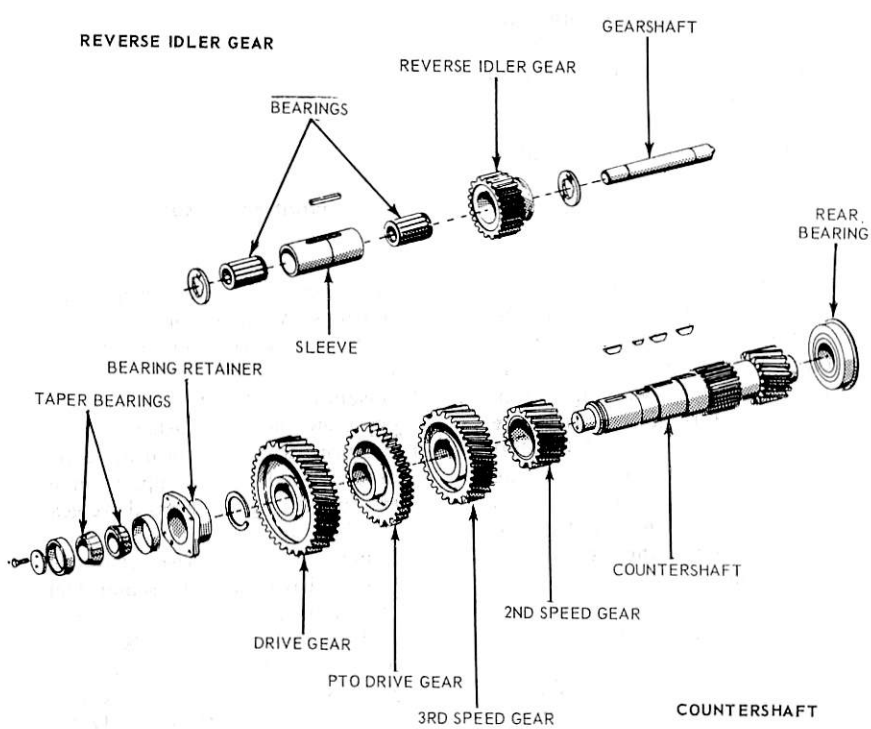

FIG. 8 Reverse Idler Gear and Countershaft Components

4. Assemble the third-speed gear sub-assembly to the mainshaft with the flange of sleeve down or toward the second-speed gear.
5. Aligning the two locking ball notches at the upper end of the sleeve with the splines of the mainshaft, lock the sleeve to the shaft with the lock balls in the bottom of the shaft splines and notches of the sleeve.
6. Check the second-speed gear for free rotation after the sleeve is in place.
7. Assemble third-fourth clutch gear to the shaft splines with the ground end down against the third-speed gear. Both ends are ground and there is no snout on this gear.
8. Assemble the snap ring to the mainshaft to lock the clutch gear in place. Use caution when assembling the snap ring to the shaft to prevent extending or distorting the snap ring. All snap rings must seat firmly in grooves to give secure locking action.
9. **Assemble the pilot bearing to the end of the mainshaft. Using a piece of tubing against the inner race of the bearing to tap onto the shaft, seat the bearing firmly against shaft shoulder.**
10. Reverse the position of the mainshaft in the vise so that the assembly rests on the third-speed gear and protective vise jaws clamp on the clutch gear.
11. Assemble first and second-speed sliding clutch gear to the shaft splines with the shift fork collar up or toward the rear of the shaft.
12. With the needle bearing roller and spacer assembled into the bore of the first-speed gear, assemble the sleeve onto the mainshaft. Seat sleeve firmly against the shoulder of the shaft.
13. Assemble the first-speed gear sub-assembly onto the shaft and onto the sleeve with the clutch teeth of the gear down, or toward the center spline section.
14. Apply a heavy coat of grease to the first-speed gear thrust washer and assemble onto the shaft and against the face of the first-speed gear.
15. If the thrust washer is a loose ID fit, use a heavy rubber band or similar device to hold the washer and needles in place.
16. **Remove the shaft assembly from the vise. Apply a light coat of grease to the splines and assembly thirdfourth speed clutch collar to the clutch gear. Position the mainshaft rear drive gear bearing retainer under Arbor and press the bearing into the retainer. Use a suitable tube to permit pressing on the outer race of the bearing.**
17. **Turn the mainshaft drive gear bearing and retainer over on the Arbor. Support the inner race of the bearing and press the mainshaft rear drive gear through the bearing until the bearing seats against the shoulder of the rear drive gear.**
18. **Remove the drive gear and bearing sub-assembly from the Arbor Press and assemble the bearing lock nut to the drive gear threads. Torque the lock nut to 550-600 ft-lbs. Stake the nut in two places provided on drive gear.**

COUNTERSHAFT

Disassembly

1. Remove the drive gear snap ring.
2. Press the countershaft out of the gears one at a time by supporting behind the gear as close to the hub as possible.
3. Remove the Woodruff keys.

Assembly

1. If Woodruff keys, or the keyways have become burred or damaged during disassembly, dress with a file before reusing them to prevent metal chip damage to the gear hub faces. As new countershaft gears have a **shrink (or interference) fit of 0.0015 to 0.003 inches, the gear bores should preferably be expanded before assembly to the shaft. Boiling water, or steam or hot oil (not to exceed 250 degrees F) can be used for this. Any other heating method will damage the gears and adversely affect their service life.**

If heat is not used, coat the gear bores, and the shaft, liberally with white lead to prevent galling or seizing of parts.

2. Assemble the Woodruff keys to the countershaft, seating them securely.
3. **In suitable Arbor Press, support second-speed gear on hub with chamfer up. Place countershaft in bore, align key and keyway and press shaft into gear until seated firmly against shoulder.**
4. In a similar manner, support third-speed gear with chamfer up. Place countershaft in bore, align key and keyway and press shaft into gear until seated firmly against gear.
5. Next, support PTO drive gear on long hub with chamfer up. Place countershaft in bore, align key and keyway and press shaft into gear until seated firmly against gear.
6. Support countershaft drive gear on short hub with long hub and chamfer up. Place countershaft in bore, align key and keyway and press shaft into gear until seated firmly against gear.
7. Assemble snap ring to countershaft to lock drive gear in place.

Use caution when assembling snap ring to countershaft to prevent extending or distorting snap ring. **Snap rings must seat firmly to give secure locking action.**

AUXILIARY TRANSMISSION

SEPARATION OF MAIN AND AUXILIARY SECTIONS

1. From inside (near the top) of the rear case, cut the lock wire and remove the two attaching capscrews and lock washers.
2. Use a bridge chain across the holes from which the capscrews were removed to support the unit.
3. From outside the case remove the remaining capscrews, bolts and washers.
4. Separate the two units with a pry bar, while leveling the rear unit with a chain fall.

JOINING OF MAIN AND AUXILIARY SECTIONS

1. Tie the third-fourth clutch gear collar to the third-speed gear or assemble collar to rear of mainshaft. Note long snout of clutch collar points toward mainshaft.
2. Pick up the rear unit with a chain hoist attached to the output end yoke or companion flange and suspend vertically over front unit.
3. Lower rear unit into place using caution to align rear mainshaft with pocket bearing of front mainshaft and drive gear teeth with countershaft drive gear.
4. Bolt the cases together using the two drilled head capscrews, with star washers on top inside holes of rear case.
5. **Assemble five capscrews with new star washers through flange on right hand side of front case into rear case. Three capscrews and washers are assembled from rear into right hand side of front case.**
6. The longest through-bolt assembles front to rear in bottom center hole of cases. Two shorter bolts assemble to left of bottom center. Use washers and nuts on all bolts.
7. After starting all capscrews and bolts, progressively tighten and pull cases together. Torque capscrews and nuts to 120-150 ft-lbs. Lock wire the internal capscrews together.
8. Use chain hoist to lift complete assembly and lower into a horizontal position. Make sure that oil holes in gears are not plugged up with grease

to insure initial lubrication of over-running gears. Use a large pressure type oil can to force lubricant in oil holes and end slots of all mainshaft floating gears to flush out grease used during assembly of needle roller bearings.

9. Check regulator air pressure with air gauge. P.S.I. should be 50-55.

DISASSEMBLY OF AUXILIARY SECTION

1. Remove the pocket bearing from the front of the mainshaft. Use a suitable puller, if necessary, to remove the inner race.
2. Lock the unit in two gears by engaging the third and fourth-speed clutch collar with the fourth-speed gear and the first and second-speed clutch collar with the first-speed gear.
3. Remove the mainshaft rear flange lock nut. Also remove the flat washer.
4. Use a puller to remove the end yoke from the mainshaft.
5. Remove the retaining capscrews and lock washers from the mainshaft and countershaft rear bearing caps.
6. Press out the rear bearing cap oil seal. Remove the speedometer bushing if it is to be replaced.
7. Remove the speedometer drive gear and mainshaft rear thrust washer.
8. Use two pieces of hardwood to block the third-fourth speed clutch gear against the inside front of the case. Using a brass drift, drive the mainshaft forward to expose the third-fourth speed clutch gear split lock ring.
9. Remove the wood blocks and the split ring. Remove the third-fourth speed clutch collar and gear.
10. Using a brass drift, drive the mainshaft rearward and remove the rear bearing and thrust washer. **Do not lose the needle bearings.**
11. Continue to drive the mainshaft rearward and remove the following parts as the mainshaft clears their bores: Fourth speed (overdrive) gear, intact with sleeve, needle bearings and spacer, second-speed gear intact with sleeve, needle bearings and spacer, first-second speed clutch collar, first-speed gear intact with clutch gear, sleeve, needle bearings and spacer.
12. Remove the remaining mainshaft assembly out through the top of the case.
13. Cut the lock wire and remove the two retaining capscrews from the front of the countershaft. Remove the front bearing retaining washer.
14. With a brass drift, drive the countershaft assembly rearward to clear the front bearing which will remain in the case bore. The rear bearing will be driven out of the case.
15. Remove bearing retaining snap ring from rear end of shaft and use suitable puller to remove rear bearing.
16. Lift countershaft assembly out top of case.

ASSEMBLY OF AUXILIARY SECTION

1. Lower the rear end of the countershaft assembly into the case with the end of the shaft and the first-speed gear through the rear bearing bore. Lower the front of the countershaft into approximate position. Maintain alignment with a cable support or by blocking up the drive gear.
2. Align the outer race assembly of the rear bearing with the inner race and rear bore and top the bearing flush with the case.
3. Assemble the countershaft rear bearing cap gasket to the bearing cap. Install the cap and gasket in the case.
4. Dip the capscrews retaining the bearing cap in gasket cement and install the capscrews. Torque to 40-50 ft-lbs.
5. Position the front bearing on the countershaft with the external snap ring away from the case.
6. Position a wood block between the second-speed gear and the case rear wall. With tubing, drive against the inner race of the bearing until it is seated against the hub of the drive gear.
7. Secure the bearing with the retainer and capscrew. Torque the capscrew 40-50 ft-lbs.
8. Position the first-speed gear and sleeve assembly in the rear of the case with the clutch teeth facing the front of the case. Mesh the gear with the countershaft gear.
9. Install the first-second speed clutch collar to the first-speed gear.
10. Position the second-speed gear and sleeve in the case with the clutch teeth facing the first-speed gear. Mesh the gear with the countershaft gear. Move the clutch collar to neutral.
11. Lightly coat the thrust faces and splines of the mainshaft with grease. Insert the pilot bearing end of the mainshaft through the rear bearing until the shaft has passed through the second gear sleeve.
12. Position the fourth-speed gear and sleeve assembly in the case with the clutch teeth facing the front of the case. Slide the mainshaft forward through the bore of the sleeve.
13. Position the third-fourth speed clutch collar to the clutch gear with the lock ring counterbore in the end of the gear toward the front. Position the gear and collar in the case and install on the mainshaft splines.
14. Block the third-fourth clutch gear and tap the mainshaft through until the locking groove in the mainshaft is beyond the clutch gear.
15. Coat the two clutch gear lock rings with heavy grease and place in the groove of the mainshaft.
16. Tap the mainshaft rearward until the lock rings center inside the counterbore of the third-fourth speed clutch gear.
17. Position the first-speed thrust washer on the rear of the mainshaft next to the first-speed gear.
18. Position the mainshaft rear bearing onto the mainshaft with the external snap ring away from the case. Use a 3/4 inch thick strip of flat stock to block the front of the mainshaft against the inside of the case. Using a pinch bar, roll the mainshaft into position to align the outer race of bearing with the case bore. Using tubing, drive on the bearing inner race until the bearing is seated against the first-speed gear thrust washer.
19. Remove the block and continue to tap the bearing into the case bore until the snap ring is seated against the case.
20. Position the rear bearing washer and speedometer gear on the mainshaft and seat them against the rear bearing.
21. Apply a light coat of gasket cement to the OD of the rear bearing cap oil seal and press it into the cap.
22. Apply gasket cement to the mainshaft rear bearing cap gasket and install it on the cap. Be sure the oil passages are aligned.
23. Install the rear bearing cap on the case and install the capscrews.
24. Install the flange on the mainshaft. **Do not drive the flange on the mainshaft unless the shaft has been blocked to prevent it from moving forward. Also do not damage the pilot surfaces or bearing diameters.**
25. Install the flat washer and lock nut on the flange. Lock the unit in two gears and torque the lock nut to 400-450 ft-lbs.
26. Torque the countershaft front lock nut to 550-600 ft-lbs. Stake the nut in the slot in the shaft.
27. Shift the clutch collars back into neutral to be sure all shafts turn

freely.

28. Install the drive gear pocket bearing.

AUXILIARY SECTION SUB-ASSEMBLIES

MAINSHAFT

Disassembly

1. **Using an Arbor Press, press the shaft out of the rear bearing and first-speed thrust washer.**

Assembly

1. Due to variations in tolerances and to provide better bearing lubrication, needle bearings should not completely encircle the shaft. Space for approximately one needle should be left unfilled on all needle bearing applications. This will aid in preventing seizures by allowing easier oil entry and free movement of the needle bearings.

To reassemble needle roller bearings, the following steps are suggested. If, however, it is more convenient to assemble needle bearing to inside of gears rather than on shaft and sleeve, the method is applicable.

2. Place the first-second speed clutch gear on the bench with the flange down. Apply a light coat of grease to the area above the flange. Assemble one row of 72 needle bearings to the clutch gear and install the spacer. Apply a light coat of grease and assemble the second row of 72 needle bearings.
3. With the clutch teeth down toward the flange, assemble the first-speed gear to the clutch gear, over the needles and spacer.
4. Coat the second-speed gear sleeve lightly with grease and install two rows of 72 needle bearings with a spacer between.
5. Install the second-speed gear on the sleeve and bearing with the clutch teeth of the gear away from the flange.
6. Place the fourth-speed gear sleeve on the flat plate and coat the sleeve with a light coat of grease. Install two rows of 62 needle bearings with a spacer between.
7. Assemble the fourth-speed gear to the sleeve and bearing with the clutch teeth facing upward.

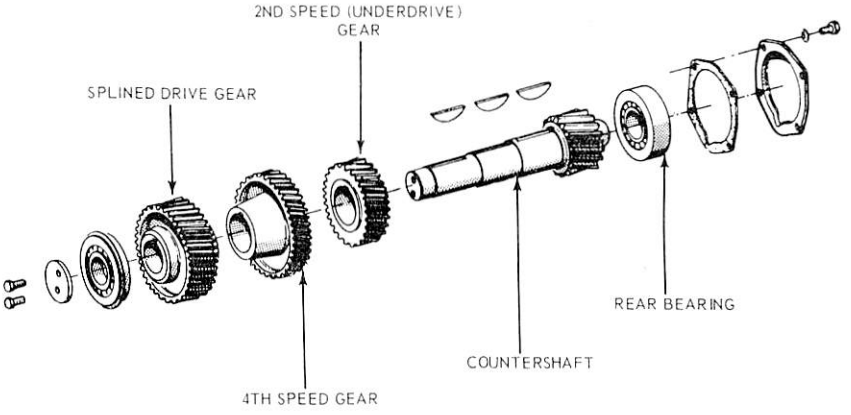

FIG. 9 Rear Unit Countershaft Components

COUNTERSHAFT

Disassembly

1. Remove the front bearing by tapping out with a soft hammer.
2. Press the countershaft out of the gears (one at a time) by supporting each gear with paralled bars as close to the hub as possible. Remove the drive gear and the third-speed (overdrive gear).
3. Remove the two exposed Woodruff keys (Fig. 9).
4. Support the first-speed (underdrive) gear and press the countershaft out of the PTO drive gear spacer at the same time.
5. Remove the remaining Woodruff key.

Assembly

1. If the Woodruff keys, or the keyways have been burred or damaged during disassembly, dress with a file before reusing them to prevent metal chip damage to the gear hub faces.

As new countershaft gears have a shrink (or interference) fit of 0.0015 to 0.003 inches, the gear bores should preferably be expanded before assembly to the shaft. Boiling water, steam or hot oil (not to exceed 250 degrees F) can be used for this. **Any other heating method will damage the gears and adversely affect their service life.**

If heat is not used, coat the gear bores, and the shaft, liberally with white lead to prevent galling or seizing of parts.

2. Assemble Woodruff key to the countershaft and seat securely.
3. Using an Arbor press, support the first-speed (underdrive gear) on the hub (with the long hub and chamfer up). Place the countershaft in position, align the key with the keyway and press into gear until the shoulder on the countershaft seats firmly against the gear.
4. Assemble the PTO drive gear spacer to the shaft and seat it against the gear. Assemble the remaining Woodruff keys to the countershaft and seat securely.
5. **Using the Arbor Press, support under the hub of the third-speed (overdrive) gear with long hub down and chamfer up. Place the countershaft into position, align key with keyway, and press into gear until seated against the** spacer.
6. In a similar way, support the countershaft drive gear with the long hub and chamfer up.
7. Press the countershaft sub-assembly into the gear until it is seated against the third-speed gear.
8. Either a one piece or separable bearings will be found as the rear countershaft bearing. If a separable bearing is used, press on the inner race with flange seated against shoulder of the countershaft. Assemble the snap ring to retain the bearing.

DESCRIPTION

AUXILIARY TRANSMISSION

Models 5831, 7231 and 8031 are Three-Speed Auxiliary transmissions. Models 7041 and 8341 are four-speed auxiliaries.

All are installed behind the main transmission with remote controls mounted in the cab.

REMOVAL AND INSTALLATION

AUXILIARY TRANSMISSION

ALL MODELS

Removal

1. Position the vehicle so that the auxiliary transmission can be easily reached and drain the lubricant.
2. **Remove the cotter pins and clevis pins from the auxiliary transmission shift rods as follows: Move each shift rod into the forward position, remove the pins and push each shaft to the neutral position.**
3. Disconnect the U-joint at the front of the auxiliary transmission.
4. Disconnect the U-joint at the rear of the auxiliary transmission and tie the drive shaft out of the way.
5. Disconnect the speedometer cable from the transmission. If the speedometer cable cannot be readily disconnected, remove the parking brake drum and linkage, then disconnect the speedometer cable.
6. Remove the parking brake adjusting rod clevis pin and disconnect the parking brake lever to cam connector.
7. Position a transmission jack under the transmission. Fasten the transmission to the jack with the safety chain.
8. Remove the transmission mounting stud or bolt insulator nut cotter pins and nuts. **When studs are used, do not disturb the stud-to-mounting bracket nuts.**
9. Lower and remove the transmission.

Installation

1. Place the transmission on the jack, secure it with the safety chain and roll the jack under the truck.
2. Position the insulators and reinforcements, if used, on the transmission mounting brackets. Raise the transmission into position (Figs. 1 and 2).
3. Install the remaining insulators. Install the retaining nuts and washer. Adjust the auxiliary transmission so that it is paralled to the main transmission within plus or minus 1/2 degree. The coupling shaft between the two transmissions must be parallel to the transmissions from zero degrees to one degree up at the auxiliary transmission end. Notice in Fig. 1 that the two front adjusting bolts and the two rear adjusting bolts must have final adjusting dimensions within 1/8 inch of each other respectively. Torque to specifications. Install the cotter pins.
4. Install the speedometer cable. Torque the cable clip retaining capscrew to 5-7 ft-lbs. If the parking brake drum has been removed, install the drum and linkage. Attach the parking brake connector to the adjusting rod with a clevis pin.
5. Position the drive shaft and connect the rear U-joint.
6. Connect the gear shift connecting rods to the transmission shift rods with clevis pins and new cotter pins.
7. Connect the U-joint at the front of the auxiliary transmission and torque the trunnion bolts to specification.
8. Fill the transmission. Adjust the parking brake and shift linkage if required.

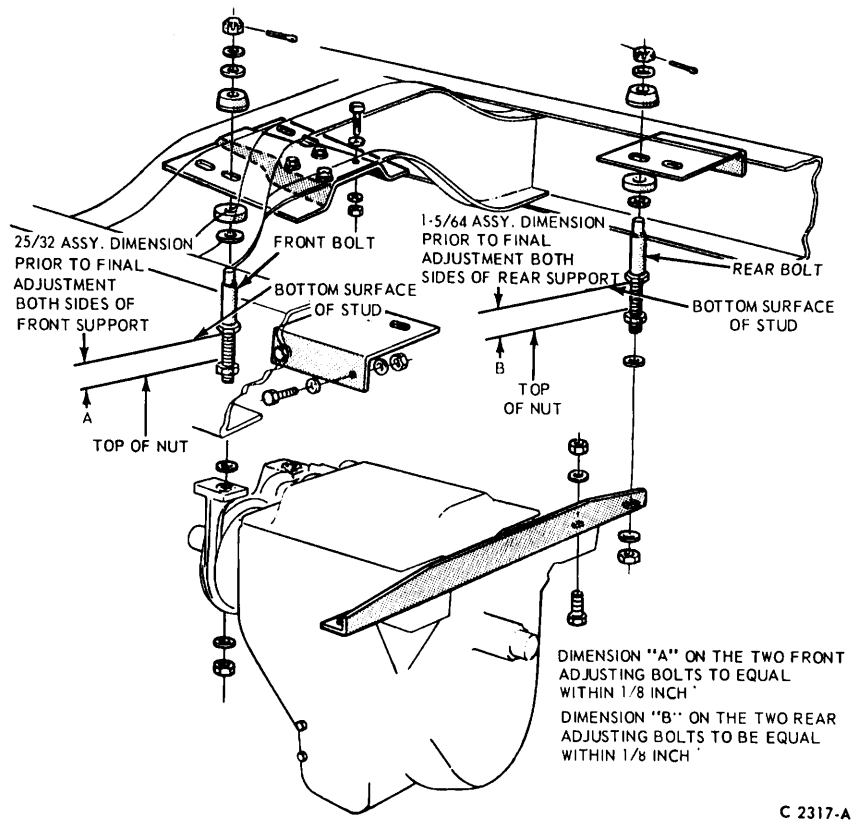

FIG. 1 Transmission Mounting Details

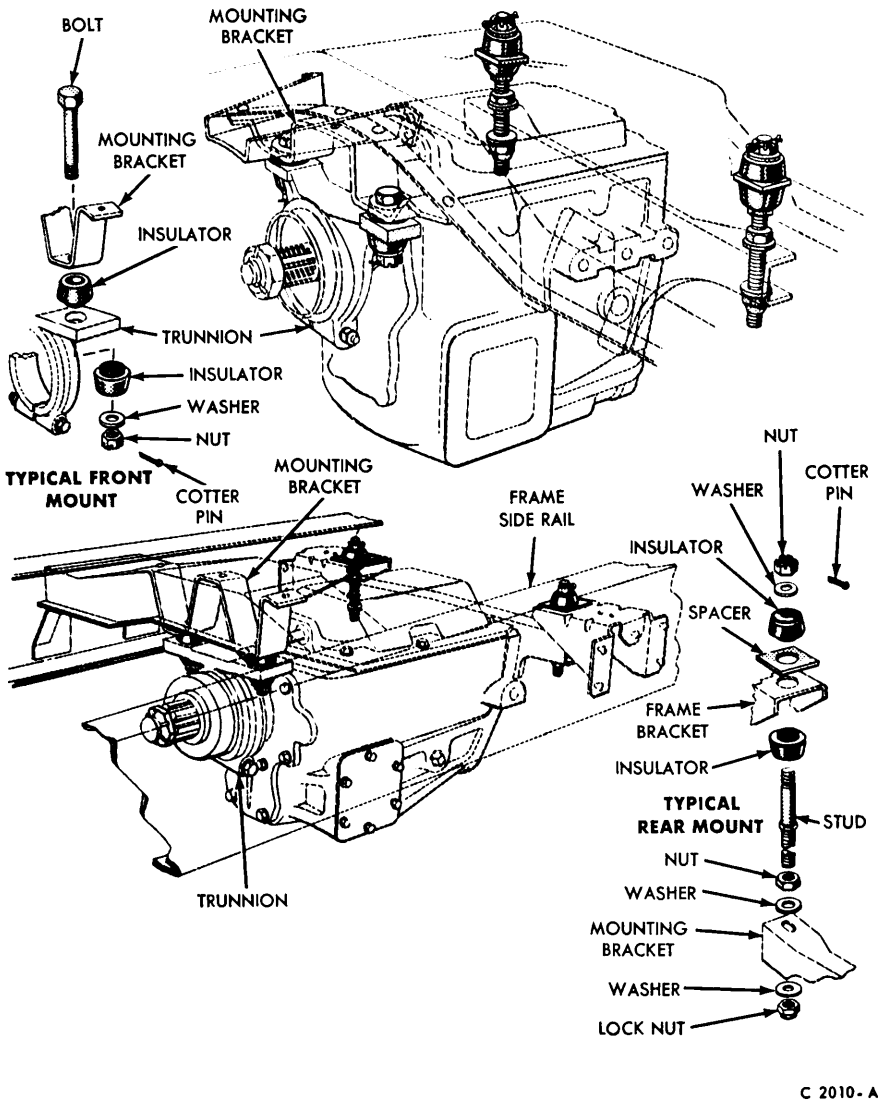

FIG. 2 Transmission Mounting Details—Models 5831 and 7231

DISASSEMBLY AND ASSEMBLY

AUXILIARY TRANSMISSION MODEL 7231

Disassembly

1. Install the transmission assembly in an overhaul stand and remove the gear shift housing.
2. Lock the transmission in two gears, remove the input shaft yoke nut and the yoke.
3. Remove the support from the front bearing retainer.
4. Remove the output shaft flange nut and the flange (and the brake drum).
5. Remove the parking brake shoe assembly from the bearing retainer.
6. Remove the output shaft rear bearing retainer and gasket and remove the speedometer drive gear from the output shaft. Remove the oil seal from the bearing retainer.
7. Remove the countershaft rear bearing cap and shims, keeping the shims together for assembly.
8. Remove the input shaft bearing retainer bolts and lock washers. Remove the retainer and the input

shaft as an assembly (Fig. 3).

9. With a soft hammer, tap the underdrive gear toward the rear of the case until the rear bearing clears the case (Fig. 4). Using Tool CG-300-3, remove the bearing.
10. Remove the underdrive sleeve and the hub through the rear bearing bore and remove the output shaft.
11. With a brass drift and a hammer, drive the countershaft toward the rear of the case until the rear bearing cup is out of the case. Slide the countershaft toward the rear until the front of the shaft clears the front bearing bore and remove the shaft (Fig. 5).
12. With a brass drift, remove the countershaft front bearing cup.

Assembly

Coat all parts with transmission lubricant to prevent scoring when the transmission is first operated.

1. Install the countershaft front bearing cup, using a soft hammer.
2. Lower the rear end of the countershaft into the countershaft rear bearing bore and position the shaft in the case.
3. Install the rear bearing cup.
4. Position the rear bearing cap **without shims** and tighten the bolts.
5. Measure the clearance between the cap and the case. Select a shim (or shims) which will permit countershaft end play of 0.001 to 0.003 inch. After adjustment has been made, torque the bolts to specification.
6. Position the output shaft in the case and slide the hub and the underdrive sleeve onto the shaft.
7. With the rear end of the output shaft extended beyond the rear end of the case, drive the rear bearing onto the shaft.
8. Drive the rear bearing and the output shaft forward until the bearing is firmly seated in its bore.
9. Apply B5A-19554-A sealing compound to the outside diameter of a new output shaft oil seal and install the oil seal, using the tool shown in Fig. 6.
10. Install the speedometer drive gear on the output shaft. Apply B5A-19554-A sealing compound to a new output shaft and rear bearing retainer gasket and install it. Torque the bolts to specification.
11. Install the input shaft and bearing retainer as an assembly. Tighten the bolts securely.
12. Install the parking brake shoe assembly and torque the bolts to specification.
13. Lock the transmission in two gears, position the output shaft flange on the shaft and install the retaining nut. Torque the nut to specification and install a cotter pin.
14. If the brake drum was removed, install it and torque the mounting nuts to specification.
15. Install the support, but do not torque the support bolt.
16. Position the input shaft yoke on the shaft and install the retaining nut. Torque the nut to specification and install a cotter pin.
17. Shift the transmission gears into neutral, apply B5A-19554-A sealing compound to a new gear shift housing gasket and position the gasket on the case.
18. Position the gear shift housing on the transmission case and install the retaining bolts and lock washers.

SUB-ASSEMBLIES MODEL 7231

INPUT SHAFT AND BEARING RETAINER

Disassembly

1. Using the tool shown in Fig. 7, remove the input shaft (with the rear bearing) from the front bearing and retainer.
2. Remove the bearing spacer and press off the rear bearing.
3. Using a soft drift, tap the front bearing and the oil seal out of the bearing retainer.

Assembly

1. Position the rear bearing snap ring on the input shaft.
2. Press the rear bearing onto the input shaft.

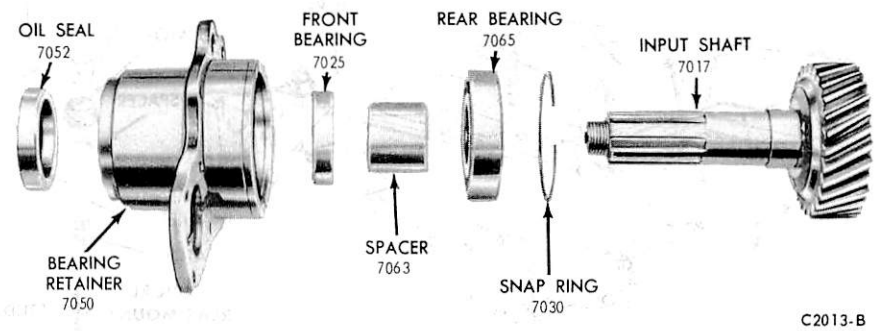

FIG. 3 Input Shaft and Related Parts—Model 7231

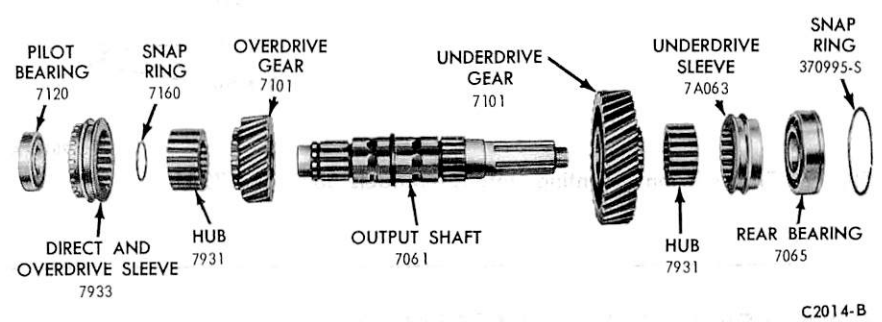

FIG. 4 Output Shaft Disassembled—Model 7231

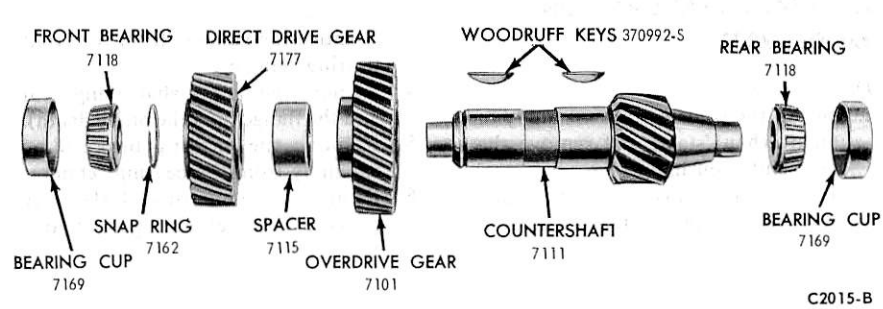

FIG. 5 Countershaft—Disassembled—Model 7231

3. Position the input shaft and bearing in the bearing retainer and install the snap ring in the retainer.
4. Install the spacer on the input shaft.
5. Install the front bearing on the input shaft.
6. Apply B5A-19554-A sealing compound to the outside diameter of a new input shaft oil seal and install the oil seal in the bearing retainer.

OUTPUT SHAFT

Disassembly

1. Slide the underdrive gear off the shaft.
2. Using the direct and overdrive sleeve as a hammer, remove the pilot bearing from the front of the output shaft.
3. Remove the snap ring from the shaft. Remove the hub and the overdrive gear.

Assembly

1. Press the overdrive gear onto the shaft and position the hub on the shaft with the flat side of the hub toward the overdrive gear.
2. Install the snap ring, seating it solidly in the groove.
3. Position the direct and overdrive sleeve on the hub.
4. Install the pilot bearing on the shaft.
5. Slide the underdrive gear onto the shaft.

COUNTERSHAFT

Disassembly

1. Remove the countershaft drive gear snap ring from its groove in the shaft, leaving the ring on the shaft behind the bearing.
2. Position the countershaft in a press and, using a press plate, press the shaft out of the drive gear, the snap ring and bearing.
3. Press the overdrive gear and the spacer off the shaft. The spacer will push the drive gear Woodruff key out of its groove.
4. Using a suitable puller, remove the rear bearing from the shaft.

Assembly

1. Install the overdrive gear Woodruff key. Press the overdrive gear and spacer onto the countershaft.
2. Install the drive gear Woodruff key and press the drive gear onto the shaft. Install the snap ring.
3. Press the front and rear bearings onto the countershaft.

GEAR SHIFT HOUSING

Disassembly

1. Remove the shift rod spring and ball plug from the side of the housing. Remove the spring and ball.
2. Remove the lock wire and set screw from the direct and overdrive shifter fork. Slide the direct and overdrive shifter shaft out of the front of the housing and remove the shift rod. Remove the plunger from the housing.
3. Remove the lock wire and set screw from the underdrive shifter fork. Pull the underdrive shift rod out of the front of the housing and remove the shifter fork. Remove the ball and spring from the housing.
4. If the oil seals in the front of the housing are damaged or cause oil leaks, remove the seals from the cover.

Assembly

1. Place the housing in a vise with the plunger spring and ball opening in the housing at the top. Dip the spring in transmission lubricant and position it in the housing.
2. **Place one of the shift rod balls on top of the spring. Insert the underdrive shift rod (longer shaft) through the front of the housing. Hold the ball down and push the shift rod through the center support. The notches in the rod must be indexed with the ball.**
3. Pull the shift rod back far enough to permit installation of the underdrive shifter fork. Install the fork on the shaft. **With the longer hub of the fork toward the front of the housing, align the lock screw hole in the fork with the lock screw recess in the shift rod. Install the lock screw, tighten it solidly and install a new lock wire. Shift the rod and fork assembly to neutral position.**
4. Insert the plunger in the cross hole in the cover. Insert the direct and overdrive shift rod into the housing. Position the direct and overdrive shifter fork on the rod and slide the rod through the center support. Align the lock screw hole in the shifter fork with the lock screw recess in the shift rod and install the lock screw. Secure the lock screw with a new lock wire.
5. **Install the shift rod ball, dip the spring in new transmission lubricant and position the spring on top of the ball. Secure the spring with the retaining plug. Tighten the plug.**
6. If the housing shifter shaft oil seals were removed, place the new oil seals, dipped in transmission lubricant, over the front ends of the two shifter shafts with the lips of the seals toward the rear of the cover. Press them carefully into place. Make certain the lips of the seals are not damaged during installation. Shift the direct and overdrive shifter shaft and fork assembly to the neutral position.

MODEL 8031

Disassembly

1. Remove the gearshift housing and install the transmission assembly in the overhaul stand.
2. Lock the transmission in two gears and remove the input and output shaft U-joint flanges by removing the nuts and using a companion flange puller to remove the flanges from the shafts.
3. Remove the support.
4. Remove the front bearing retainer cap (Fig. 8) and gasket.
5. Remove the lock washers from the retainer cap bolts and install the retainer cap (without washers) as shown in Fig. 9.

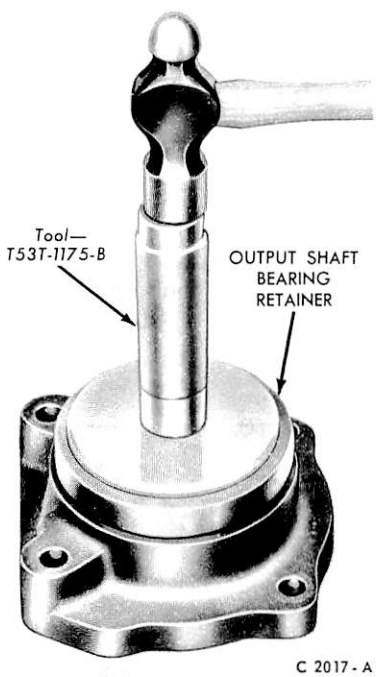

FIG. 6 Installing Output Shaft Rear Oil Seal—Model 7231

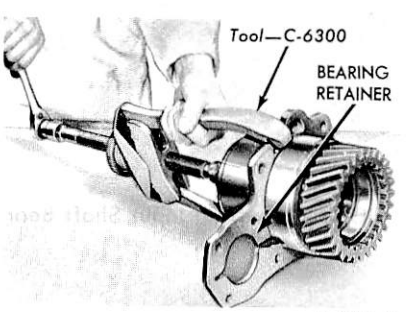

FIG. 7 Removing Input Shaft Bearing—Model 7231

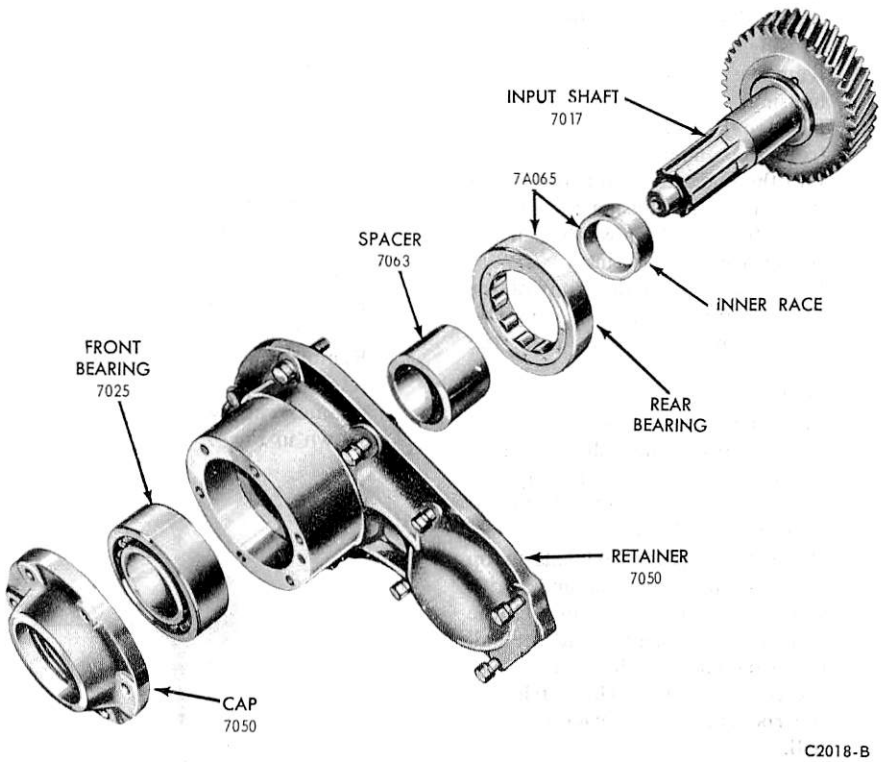

FIG. 8 Input Shaft and Related Parts—Model 8031

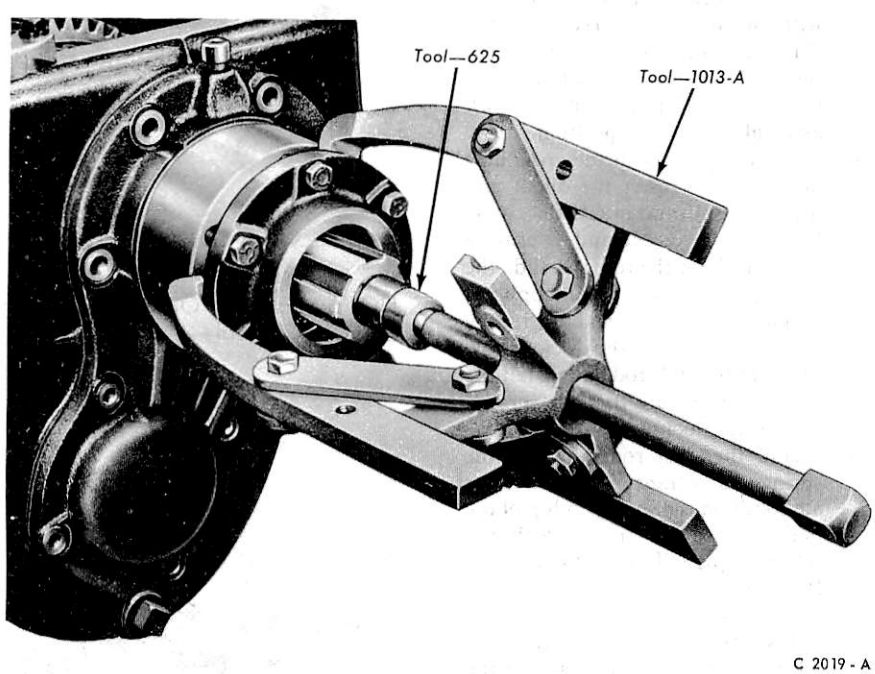

FIG. 9 Removing Input Shaft Bearing Retainer—Model 8031

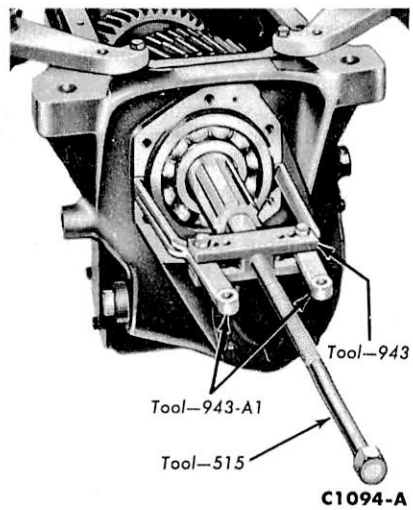

FIG. 10 Removing Output Shaft Rear Bearing—Model 8031

6. After removing the bolts from the retainer, remove the retainer and front bearing as shown in Fig. 9. remove the cap and tap the front bearing out of the retainer.
7. Remove the parking brake shoe plate. Remove the output shaft bearing retainer, the speedometer drive gear and the rear bearing flat washer.
8. Slide the output shaft assembly toward the rear of the transmission until the rear bearing has enough clearance for a standard bearing puller to be placed on the snap ring of the bearing. Pull the bearing off the output shaft (Fig. 10).
9. Remove the second and third-speed clutch gear lock washer and nut by unlocking the tang on the lock washer. Hold the nut with a spanner wrench while rotating the output shaft until the nut is removed from the shaft.
10. Install the nut and puller on the rear of the output shaft and pull the output shaft out through the rear of the case (Fig. 11).
11. Remove the output shaft nut, lock washer, flat washer, second and third-speed clutch gear and clutch collar, output shaft overdrive gear and sleeve, and the output shaft first-speed gear through the gear shift cover opening. The needle roller bearings in the first-speed gear will fall out when removing the output shaft.
12. Remove the first-speed clutch gear and collar from the output shaft.

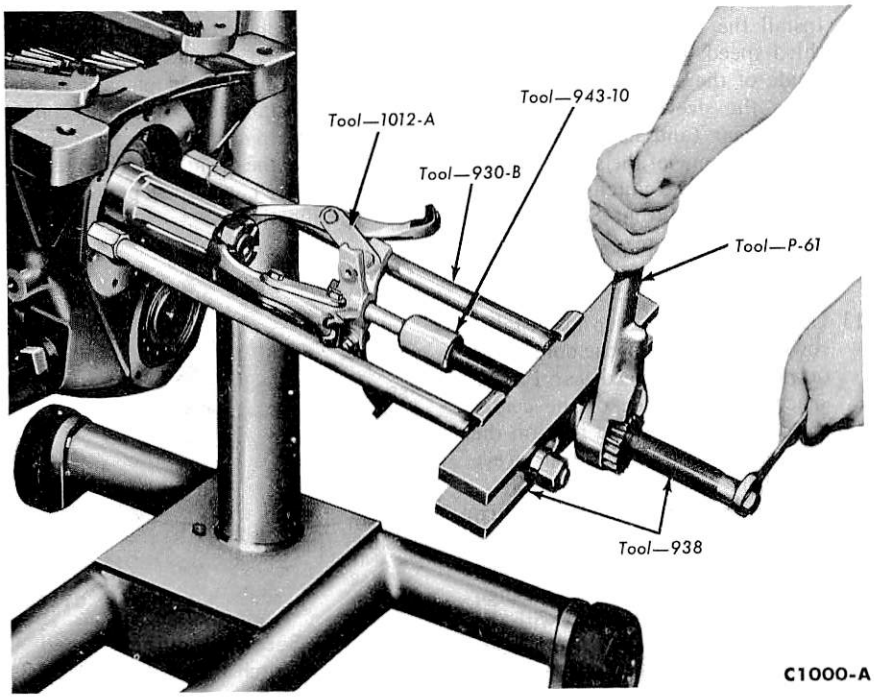

FIG. 11 Removing Output Shaft—Model 8341

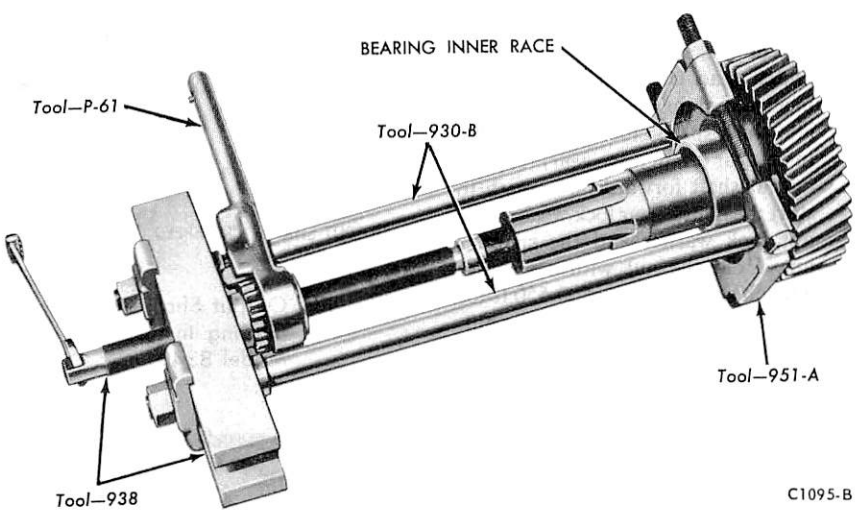

FIG. 12 Removing Input Shaft Rear Bearing Inner Race—Model 8341

13. Remove the input shaft and bearing out through the gear shift cover opening and remove the output shaft front pilot bearing from the input shaft and gear.
14. Remove the roller bearing and bearing spacer from the input shaft. Remove the inner bearing race from the input shaft using the tools shown in Fig. 12.
15. Remove the countershaft front bearing retainer washer and the rear bearing cap and gasket.
16. **Using the tool shown in Fig. 13, press the countershaft toward the rear until the shaft is free from the front bearing and the rear bearing is out of the case.**
17. Remove the countershaft rear bearing snap ring from the rear of the countershaft.
18. Using the tool shown in Fig. 14, remove the rear bearing from the shaft. Remove the front bearing from the case.
19. Remove the countershaft from the case, front end first, through the gear shift cover opening (Fig. 15).

Assembly

1. With the aid of a suitable sling (Fig.

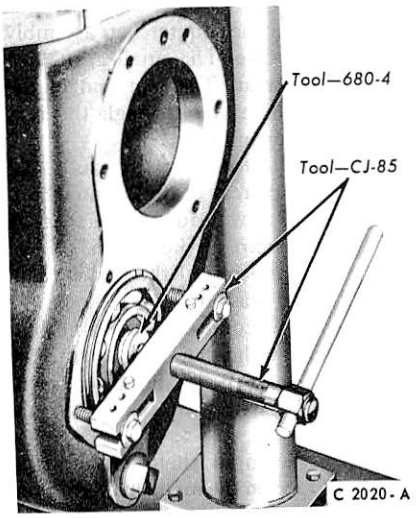

FIG. 13 Removing Countershaft—Model 8341

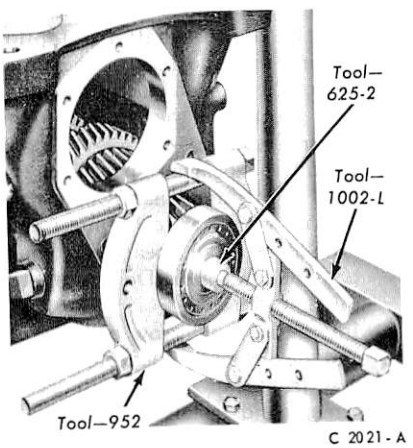

FIG. 14 Removing Countershaft Rear Bearing—Model 8341

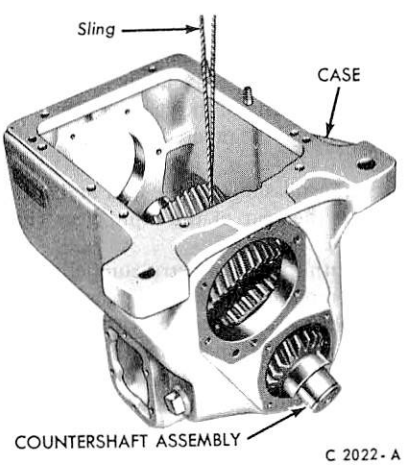

FIG. 15 Removing or Installing Countershaft—Model 8341

15), lower the countershaft assembly into the case. The small gear must face the rear. The rear end of the shaft will extend through the rear bearing opening.

2. Install the roller bearing and snap ring on the rear of the countershaft. Coat a new countershaft rear bearing cap gasket with gasket cement and install the gasket, cap, bolts and washers.
3. Place the countershaft front ball bearing on the shaft and tap into the case. Secure the retaining washer to the shaft with two capscrews and lock wire.
4. Press the input shaft rear bearing inner race on the input shaft with the flanged end of the race toward the gear. Use a suitably sized tube as an arbor.
5. Place the outer race and roller bearing assembly in the bore of the case and slide the gear into the bearing from the inside of the case.
6. Set the output shaft front pilot bearing into the rear of the input shaft. The flanged side of the inner race must face the rear. Tap the bearing in place.
7. Install the bearing spacer on the front of the input shaft. Coat a new gasket with gasket cement and install the gasket, bearing retainer, bolts and washers. Do not tighten the bolts (Fig. 8).
8. Insert the double row ball bearing and the dirt and oil deflector. Coat a new front cap gasket with gasket cement and install the gasket and cap. Install the cap bolts and washers but do not tighten them.
9. **Install the drive flange or yoke on the input shaft. Start the washer and nut. The nut cannot be tightened until the output shaft is assembled.**
10. Position the transmission, front down. Install the second and third-speed clutch gear into the second and third-speed clutch collar. The ground end of the gear must face the rear and the tapered end of the collar must face the front of the transmission. Set the gear and collar on the rear of the input gear (Fig. 16).
11. With the aid of petroleum jelly, or a comparable viscosity grease, install two rows of needle bearings inside the output shaft third-speed gear. Each row will consist of 62 needles. Place the spacer between the two rows. A spacer, slightly greater than the diameter of one needle, will exist in each row when all the needles are in place (Fig. 17).
12. Install the pin in the wall of the third-speed gear sleeve from the inside of the sleeve bore (Fig. 17). Place the sleeve inside the third-speed gear (and needle bearings) with the flange of the sleeve toward the rear and the clutch teeth of the gear toward the front. Set the sleeve and gear on the rear of the second and third-speed clutch gear (Figs. 17 and 18).
13. Using grease, as in Step 11, install 3 rows of 62 needles in the bore of the output shaft first-speed gear. Place a spacer on each side of the center row. Set the first-speed gear on the rear of the third-speed gear sleeve (Fig. 19).
14. **Inspect the output shaft for dirt, damage and burrs. Coat the shaft lightly with oil and slide it through the stacked gears and sleeve. Align the long spline on the shaft with the pin in the third-speed gear sleeve. When the shaft has entered the second and third-speed clutch gear, turn the transmission so the cover opening is facing up (Fig. 20).**
15. **Move the output shaft gears and shaft as far to the rear of the case as possible without pulling the shaft out of the second and third-speed clutch gear.** Use fiber or hardwood blocks as shims between the second and third-speed clutch gear and the input gear (main drive gear). Tap the output shaft forward far enough to start the clutch gear lock washer, the nut lock washer and the spanner nut. Hold the nut with a spanner wrench and tighten to 500-550 ft-lbs by turning the output shaft rear nut. Align a slot of the spanner nut with a tang of the lock washer and bend the tang into the slot. The output shaft rear nut may be removed before the cover is installed by locking the transmission in two gears.
16. With the fiber or hardwood shims in place between the input gear and the clutch gear, install the first-speed clutch gear and collar onto the rear of the output shaft. The gear hub must be toward the rear and the long hub of the collar must be toward the front. Tap firmly into place.
17. Install the rear bearing (snap ring to rear). Remove the shims from the front of the output shaft and tap the output shaft and rear bearing forward into place. Be sure the front of the output shaft enters the pilot bearing easily.
18. Place the flat washer on the rear of the output shaft rear bearing. Install the speedometer gear on the output shaft. Coat a new rear gasket with gasket cement and place it on the case. Install the rear bearing retainer and the parking brake shoe plate. Torque the front and rear bearing retainer and cap bolts to specifications.

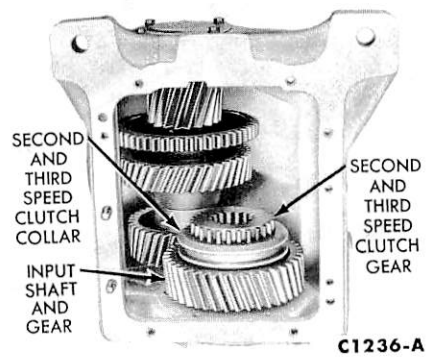

FIG. 16 Second and Third-Speed Clutch Installation—Model 8341

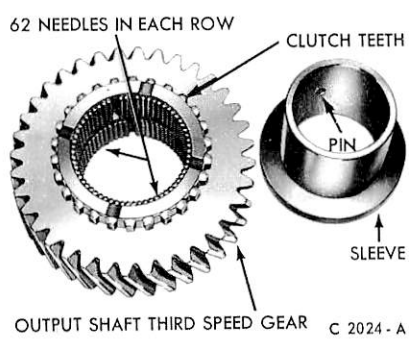

FIG. 17 Output Shaft Third-Speed Bearing Installation—Model 8341

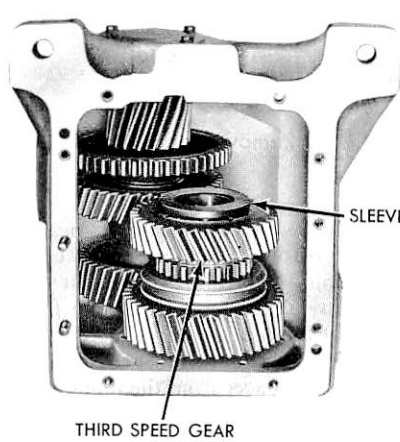

FIG. 18 Output Shaft Third-Speed Gear Installation—Model 8341

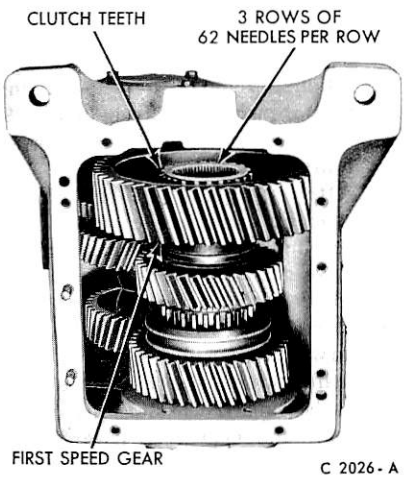

FIG. 19 Output Shaft First-Speed Gear Installation—Model 8341

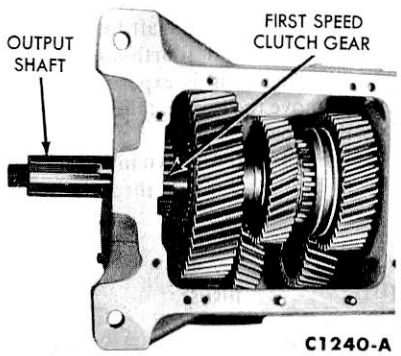

FIG. 20 Output Shaft Installation—Model 8341

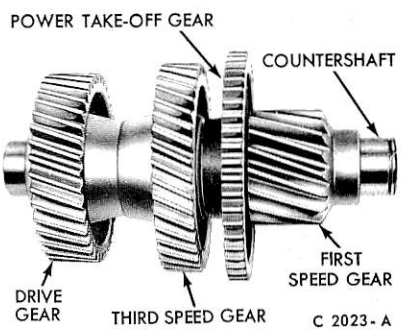

FIG. 21 Countershaft Assembly—Model 8341

19. Install the front and rear companion flanges and torque to specifications.
20. Coat a new cover gasket with gasket cement and install it and the cover. Be sure the shift forks are aligned with the shift collars in the transmission.
21. Install the support on the front bearing retainer, but do not tighten the locking nut and bolt.

SUB-ASSEMBLIES—Model 8031

COUNTERSHAFT

Disassembly

Mark the gears to show their position and sequence before removal (Fig. 21). Gears may be removed from the countershaft by supporting each gear separately on an arbor and pushing the countershaft out of the gear.

Assembly

Inspect the gear teeth, bores and shaft for wear, damage and rough surfaces. Inspect the keys and keyways for cracks, burrs or metal displacement.

1. Place the power take-off gear and key in position (long gear hub toward front). With a suitable arbor, press the power take-off gear firmly against the 1st speed gear (Fig. 21).
2. Insert the 3rd speed overdrive gear key and position the gear with the long hub facing the front of the shaft. Use a proper size arbor and press the gear into position.
3. Following the above procedure, install the drive gear (long hub toward the rear of the shaft).

GEAR SHIFT HOUSING

Disassembly

1. After cutting and removing the safety wires, remove the shift fork retaining bolts (Fig. 22).
2. Remove the retaining plug from the outside of the housing. Remove the spring, lock plunger pin and poppet ball.
3. After shifting the high speed shift rod to neutral position, remove the 1st speed shift rod from the cover and remove the 1st speed shift fork. Remove the shift rod interlock pin.
4. Remove the 2nd and 3rd speed shift rod from the cover and remove the 2nd and 3rd speed shift fork. Remove the 2nd and 3rd speed shift rod poppet ball, plunger and poppet spring.
5. If the oil seals in the front of the housing are damaged or leaking, pry the seals from the cover.

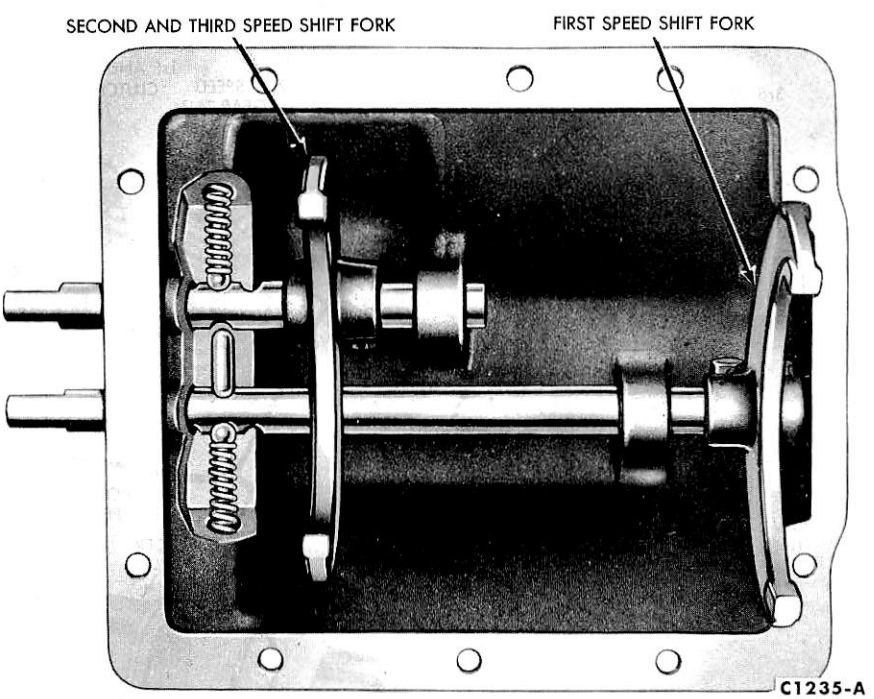

FIG. 22 Gear Shift Housing—Model 8031—Model 8341

Assembly

1. Place the shift housing upside down in a vise. Check the shift rods to make sure that they are a free sliding fit in the shift cover.
2. Dip the 2nd and 3rd speed shift rod spring in new transmission lubricant and install the spring, plunger and poppet ball in the housing.
3. **Install the 2nd and 3rd speed shift rod into the gear shift housing. Hold the poppet ball down and slide the shaft through the shift cover boss (Fig. 22).**
4. **Place the 2nd and 3rd speed shift fork on the shift rod with the long hub of the fork toward the front of the housing. Slide the shift rod through into neutral position. Align the screw holes in the fork with the notches in the shift rod. Install the two screws and lock wire the heads.**
5. Install the shift rod interlock pin.
6. Install the 1st speed shift rod into the gear shift housing and place the 1st speed shift fork on the shift rod with the long hub toward the front. Align the shift fork screw holes with the notches in the shift rod. Install the two screws and lock wire the heads.
7. Install the low speed shift rod poppet ball and plunger. Dip the spring in new transmission lubricant and position the spring on the top of the plunger. Secure the spring with the retaining plug. Tighten the plug solidly. Shift the low speed shift rod into neutral.
8. **If the housing shift rod oil seals were removed, dip new oil seals in transmission lubricant and place them on the front end of the shift rods with the lips of the seals facing inward (rear). Press them carefully into place. Make certain the lips of the seals are not damaged during installation.**

MODEL 8341

Disassembly

1. Remove the rear shift housing and gasket and mount the transmission in an overhaul stand.
2. Lock the transmission in two gears and remove the flange (and drum) from the output shaft.
3. Remove the input shaft U-joint flange and remove the dust deflector.
4. Remove the support.
5. Remove the front bearing retainer cap (Fig. 9) and gasket.
6. Remove the lock washers from the retainer cap bolts and install the retainer cap **(without washers)** as shown in Fig. 10.
7. After removing the bolts from the retainer, remove the retainer and front bearing as shown in Fig. 9. Remove the cap and tap the front bearing out of the retainer.
8. After removing the brake shoe assembly, remove the output shaft bearing retainer, the speedometer drive gear and the first-speed gear spacer washer (Fig. 23).
9. After sliding the input shaft as far forward as possible, tap the output shaft forward to start the shaft out of its bearing. Then slide the output shaft and bearing rearward until there is clearance for a standard bearing puller. Pull the bearing from the shaft (Fig. 10) and then remove the first-speed gear thrust washer.
10. Position fiber or hardwood blocks about one-inch thick between the input shaft and the third and fourth-speed clutch gear (Fig. 24).
11. Using the tool shown in Fig. 24, press the output shaft forward until the third and fourth-speed clutch gear lock ring is exposed (Fig. 25). Remove the two matched halves and the blocks.
12. Using the tool shown in Fig. 11, pull the output shaft out through the rear of the case.

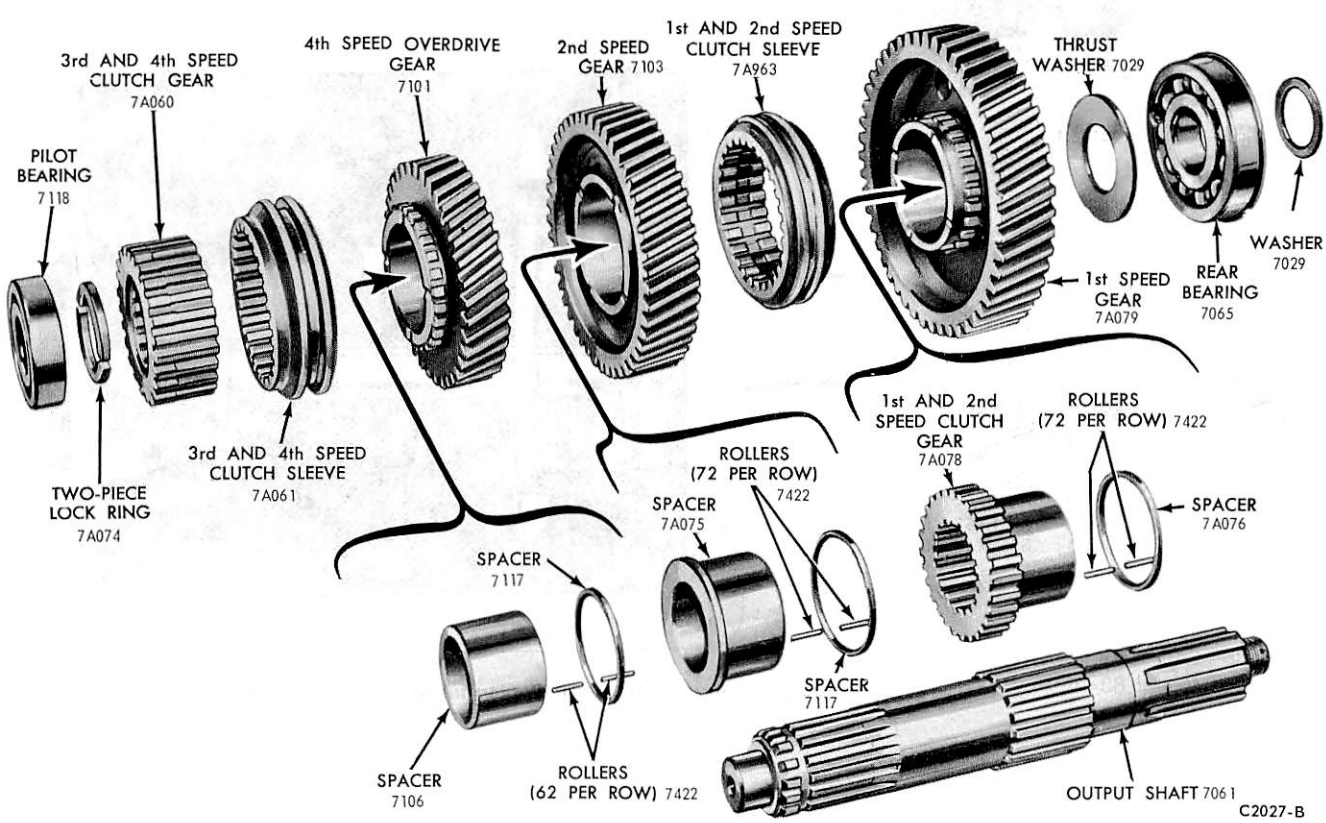

FIG. 23 Output Shaft—Disassembled—Model 8341

13. Remove the output shaft components from the case. Note that there are double rows of bearing rollers in the first, second and fourth-speed gears (Fig. 23).
15. Remove the input shaft through the top of the case and remove the pilot bearing from the input shaft. Remove the sleeve and the rear bearing inner race from the shaft. Use the tool shown in Fig. 12 to remove the inner race.
16. Remove the input shaft rear bearing from its bore in the case.
17. Remove the countershaft front bearing retainer washer (Fig. 26) and the rear bearing cap and gasket.
18. Using the tool shown in Fig. 21, press the countershaft toward the rear until the shaft is freed from the front bearing and the rear bearing is out of the case.
19. Using a standard puller (Fig. 14), remove the rear bearing from the shaft. Remove the front bearing from the case.
20. Remove the countershaft from the case, front end first.

Assembly

1. After positioning the countershaft in the case, use a suitable bearing driver to install the rear bearing on the shaft and in the case bore.
2. **Apply B5A-19554-A sealer to a new gasket, install the rear bearing cap and torque the bolts to specification. Be sure the oil drain is positioned at the bottom and safety wire the bolts.**
3. Using a suitable installer, drive the front bearing into position and install the retainer washer. Torque the bolts to specification and install the lock wire.
4. Using a suitable installer and positioning the flanged side of the inner race to the rear, press the inner race of the input shaft rear bearing onto the input shaft.
5. Position the outer race of the rear bearing in the case bore.
6. After positioning the input shaft in the case, position the pilot bearing (with the flanged end of the inner race to the rear) in the input shaft.
7. **After coating the bore of the first-speed gear with thick grease, position the rollers and the spacer (Fig. 23). Note that there must be 72 rollers in each row. Then carefully position the first and second-speed clutch gear inside the first-speed gear, with the clutch gear teeth to the front.**
8. After coating the bore of the second-speed gear with thick grease, position the rollers and the ring type spacer (Fig. 23). **Note that there**

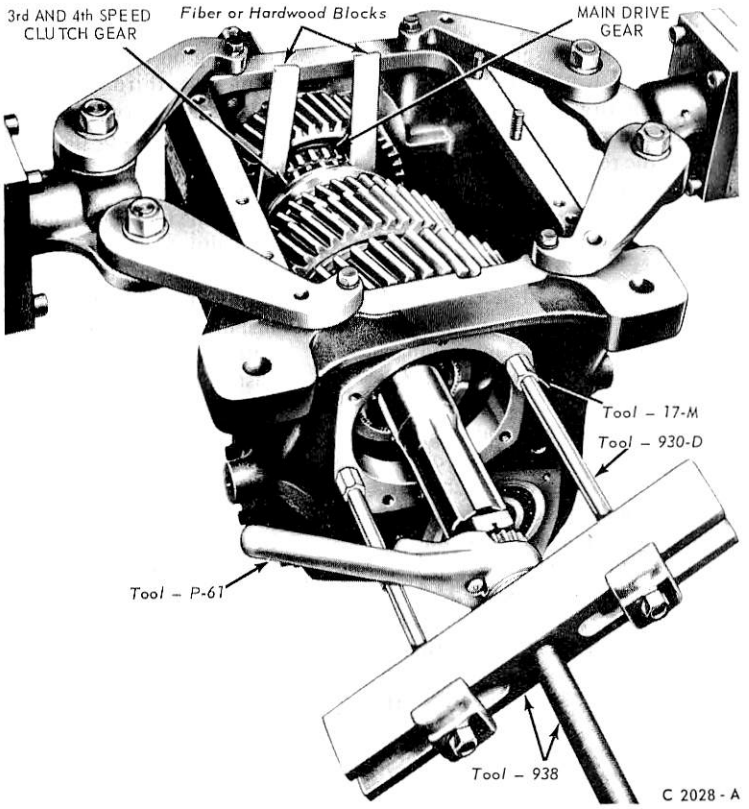

FIG. 24 Pressing Output Shaft Forward—Model 8341

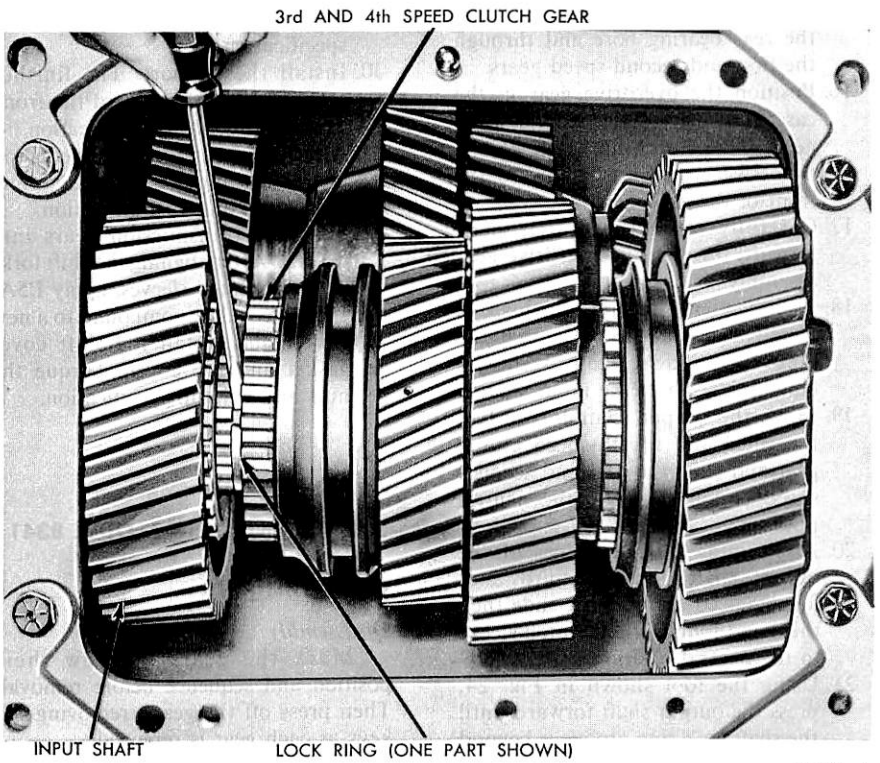

FIG. 25 Third and Fourth-Speed Clutch Gear Lock Ring—Model 8341

must be 72 rollers in each row. Then carefully insert the sleeve-type spacer inside the gear with the spacer flange to the front.

9. After coating the bore of the overdrive gear with thick grease, position the rollers and the ring-type spacer. **Note that there must be 62 rollers in each row.** Then carefully insert the sleeve-type spacer inside the gear.
10. Position the first and second-speed clutch sleeve on the first and second-speed clutch gear. **The longer hub of the sleeve must be toward the first-speed gear.**
11. Position the third and fourth-speed clutch sleeve on the splines of the third and fourth-speed clutch gear. **The longer hub of the sleeve must be toward the clutch gear end that is recessed for the lock ring.**
12. Position the first-speed gear assembly in the rear of the case. The clutch gear teeth must be toward the front of the case.
13. Position the second-speed gear assembly next to the first and second-speed clutch gear. The clutching teeth of the second-speed gear must be toward the first-speed gear.
14. Line up the two gears by sliding the first and second-speed clutch sleeve forward over the clutching teeth of the second-speed gear.
15. Position the output shaft through the rear bearing bore and through the first and second-speed gears.
16. Position the overdrive gear in the case and next to the second-speed gear. The clutching teeth of the overdrive gear must be toward the front of the case.
17. Carefully move the output shaft forward through the overdrive gear assembly.
18. Position the third and fourth-speed clutch gear and sleeve so that the sleeve can be engaged in the clutching teeth of the input shaft.
19. Move the output shaft forward to the third and fourth-speed clutch gear and slide the first and second-speed clutch sleeve to the neutral position.
20. After lining up the splines of the output shaft and the third and fourth-speed clutch gear, slide the third and fourth-speed clutch sleeve to the neutral position.
21. Using the tool shown in Fig. 24, press the output shaft forward until the shaft lock ring groove is beyond the third and fourth-speed clutch gear. Remove the blocks.
22. After coating the lock ring with heavy grease, position both parts of the ring on the shaft.
23. Slide the third and fourth-speed clutch gear forward and make sure that both parts of the lock ring will center inside the counterbore of the clutch gear.
24. Using the tool shown in Fig. 11, pull the output shaft rearward until the components are drawn into position.
25. Using a suitable bearing driver, install the output shaft rear bearing with the snap ring groove to the rear. Install the spacer washer and the speedometer drive gear.
26. Apply B5A-19554-A sealing compound to a new gasket, install the rear bearing retainer and torque the retaining bolts to specification. Install the lock wire and install the brake shoe assembly.
27. Lock the transmission in two gears and install the output shaft flange (and drum). Torque the nut to specification.
28. Position the input shaft sleeve on the shaft, apply B5A-19554-A sealing compound to a new gasket and install the bearing retainer gasket and the retainer. Torque the bolts to specification.
29. Position the front bearing in the retainer, apply B5A-19554-A sealing compound to a new gasket and install the bearing cap and gasket. Torque the bolts to specification.
30. Install the support. The finished surface should be toward the front. Torque the bolt to specification.
31. After positioning the dust deflector, install the input shaft flange and torque the nut to specification.
32. Shift the transmission gears into neutral. After aligning the shift forks with the clutch sleeves, apply B5A-19554-A sealing compound to a new gasket and install the shift cover gasket and the cover. Torque the nuts and bolts to specification.

SUB ASSEMBLIES—MODEL 8341

COUNTERSHAFT

Disassembly

Mark the gears to show their position and sequence before removal. Then press off the gears, removing the keys as each gear is removed.

Assembly

Press on the gears, **installing the keys as the gears are installed.**

GEAR SHIFT HOUSING

Disassembly

1. After cutting the safety wires, remove the shift fork retaining bolts.
2. Remove the retaining plug from the outside of the housing. Remove the spring, poppet ball and lock plunger pin (Fig. 27).
3. After shifting the third and fourth-speed shift rod to neutral position, remove the first-speed shift rod, the shift rod sleeve, the interlock pin and the shift fork.
4. Remove the third and fourth-speed shift rod, the shift fork, the spring, ball and lock plunger pin.
5. If the oil seals in the front of the housing are leaky, drive them out with a small chisel or punch.

Assembly

1. Position the third and fourth-speed ball spring in its bore, then the lock plunger pin.
2. Position the poppet ball on the pin, then start the shift rod into its bore. Position the rod so that the ball will engage one of the three equally spaced notches (Fig. 27).
3. Using a screwdriver, depress the ball far enough to start the rod over the ball, then tap the rod in about two inches.
4. After positioning the shift fork, push the rod to its neutral position and install the fork retaining bolts. Install the lock wire.
5. After positioning the interlock pin, position the first and second-speed shift rod, the sleeve and the shift fork.
6. Install the fork retaining bolts and the lock wire.
7. Install the first and second-speed poppet ball, lock plunger pin, spring and the retaining plug.
8. If necessary, install new oil seals in the shift rod bores, using a suitable installer to avoid damaging the seals.

MODEL 7041

Disassembly

1. Remove the transmission cover (Fig. 28) from the case.
2. Shift the transmission into neutral.
3. Remove the 2 detent spring retainer plugs from the right side of the case (Fig. 28) and remove the detent springs and balls.
4. Cut the lock wire and remove the lock screw from the first and second-speed shift fork. Pull the first and

second-speed shift rod out the front of the case. Remove the fork.

5. Cut the lock wire and remove the lock screw from the third and fourth speed shift fork. Pull the shift rod out of the front of the case and remove the fork.
6. Remove the interlock plunger from the interlock bore in the case.
7. Engage both sliding clutch sleeves to lock the input and output shafts.
8. Pull the cotter pins and remove the input and output shaft flange retaining nuts and flat washers.
9. Remove the input and output shaft flanges with a suitable puller.
10. Remove the input shaft bearing retainer-to-case attaching bolts.
11. Use puller screws to remove the input shaft bearing retainer and the input shaft and gear from the main case.
12. Remove the output shaft bearing retainer and gasket.
13. Remove the speedometer drive gear and spacer.
14. Remove the output shaft bearing with a suitable puller. Remove the first-speed gear thrust washer.
15. Remove the third and fourth-speed sliding clutch sleeve (Fig. 29).
16. Remove the remainder of the output shaft assembly out through the top of the case.
17. Remove the countershaft rear bearing retainer and shims. With a micrometer, measure the shim pack and tag the total shim pack thickness.
18. Tap the countershaft rearward until the countershaft rear bearing cup can be removed from the main case.
19. Tilt the front of the countershaft assembly upward and remove it through the top of the case.
20. Remove the countershaft front bearing cup from the case.

Assembly

1. Install the assembled (front and rear bearing cones installed) countershaft into the main case.
2. Install the rear bearing cup in the countershaft rear bearing bore in the main case.
3. Install the front bearing cup in the countershaft front bearing bore in the main case.
4. Adjust the countershaft bearing end play (preload) as follows:
   a. Install the front bearing retainer and gasket.
   b. Install the rear bearing retainer with a trial shim pack.
   c. Adjust the shim pack so that a 0.001 to a 0.003 inch end play is obtained on the countershaft bearings. In each trial, the bearing retainer bolts must be at proper torque. Also, the shaft must be rotated several times in each direction to seat the rollers before a final preload and/or end play check is made.
   d. After the end play and/or preload has been established, remove the front bearing retainer.
5. Place the output shaft assembly in the case.
6. Slide the first-speed gear thrust washer over the rear end of the output shaft.
7. With a suitable tool, press the output shaft rear bearing onto the shaft and into the case. The snap ring groove on the bearing OD goes to the rear.

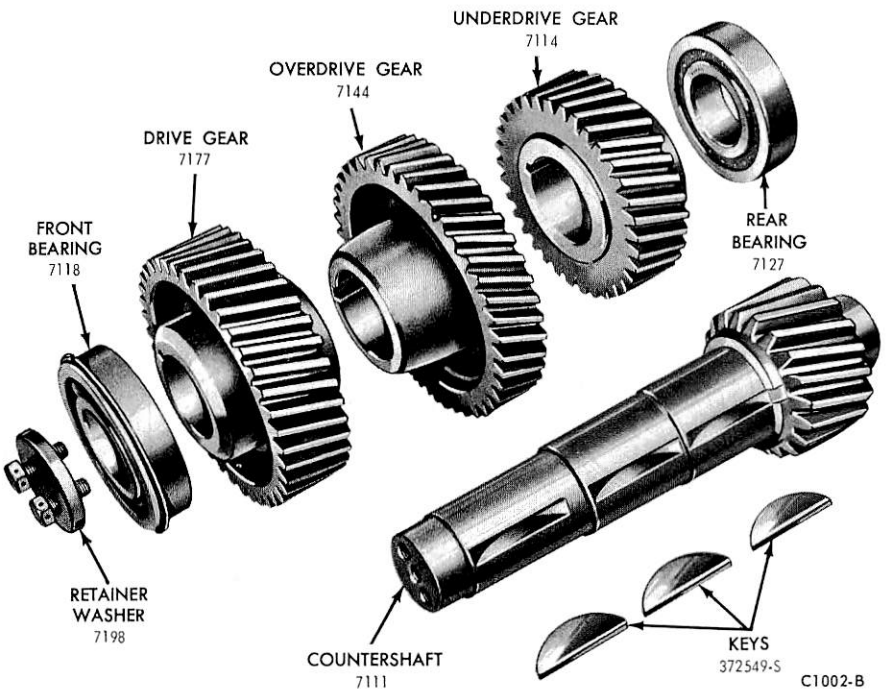

FIG. 26 Countershaft and Gear—Model 8341

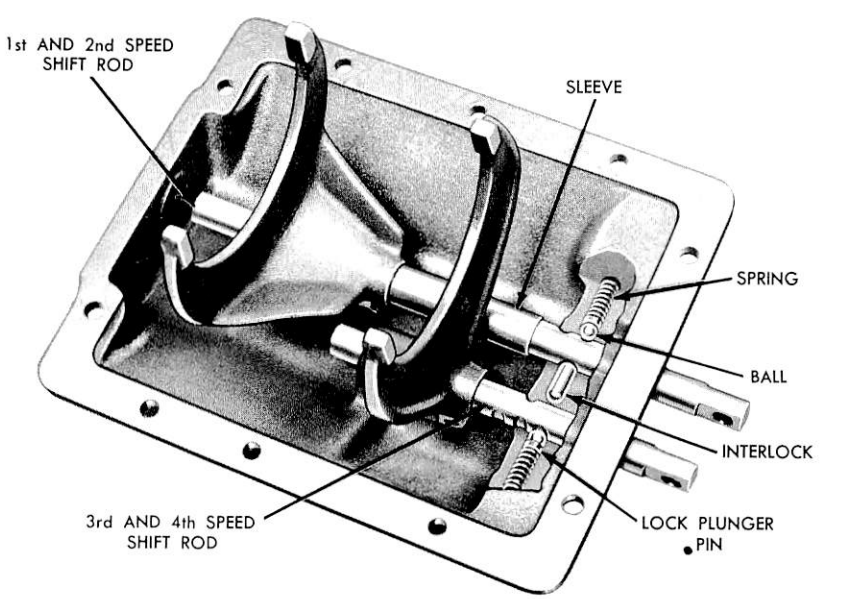

FIG. 27 Gear Shift Housing—Model 8341

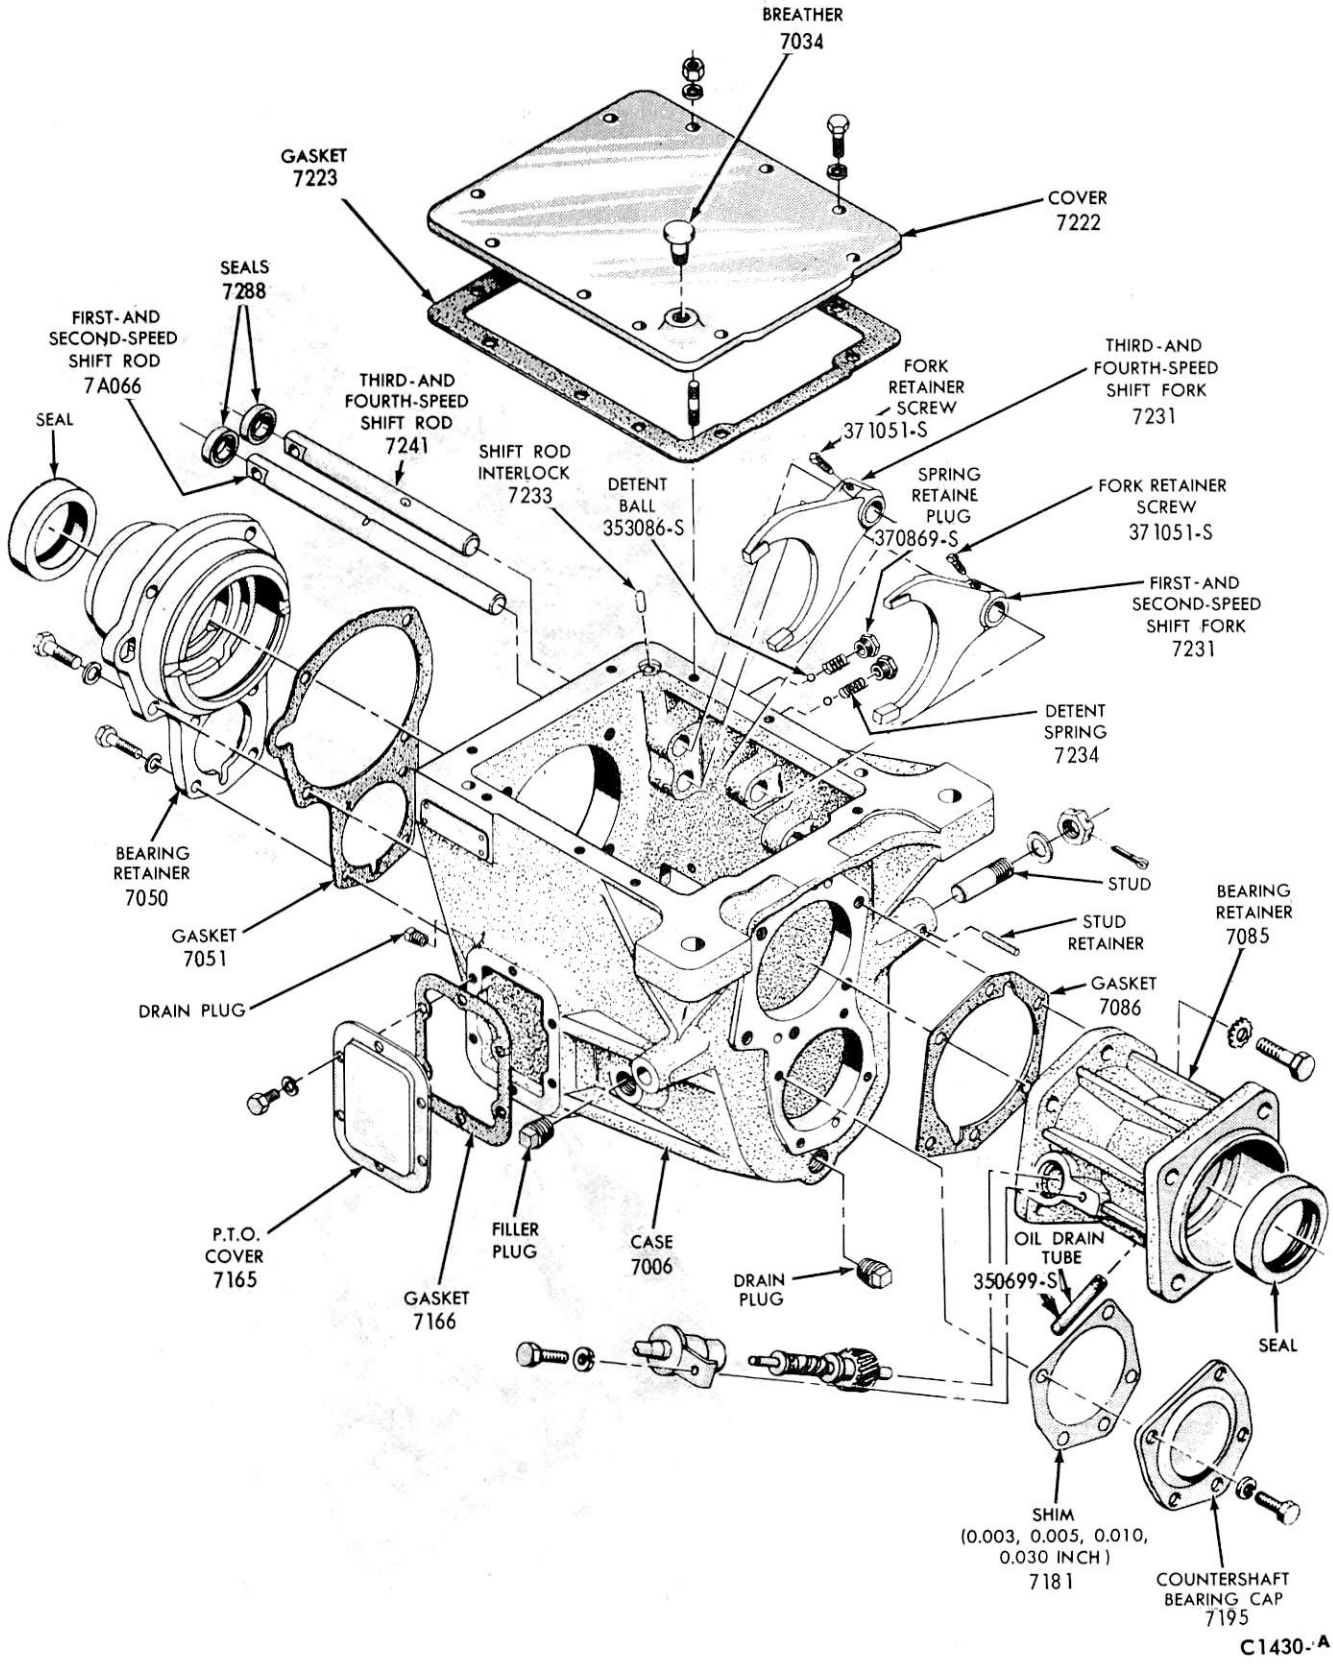

FIG. 28 Transmission Case Disassembled—Model 7041

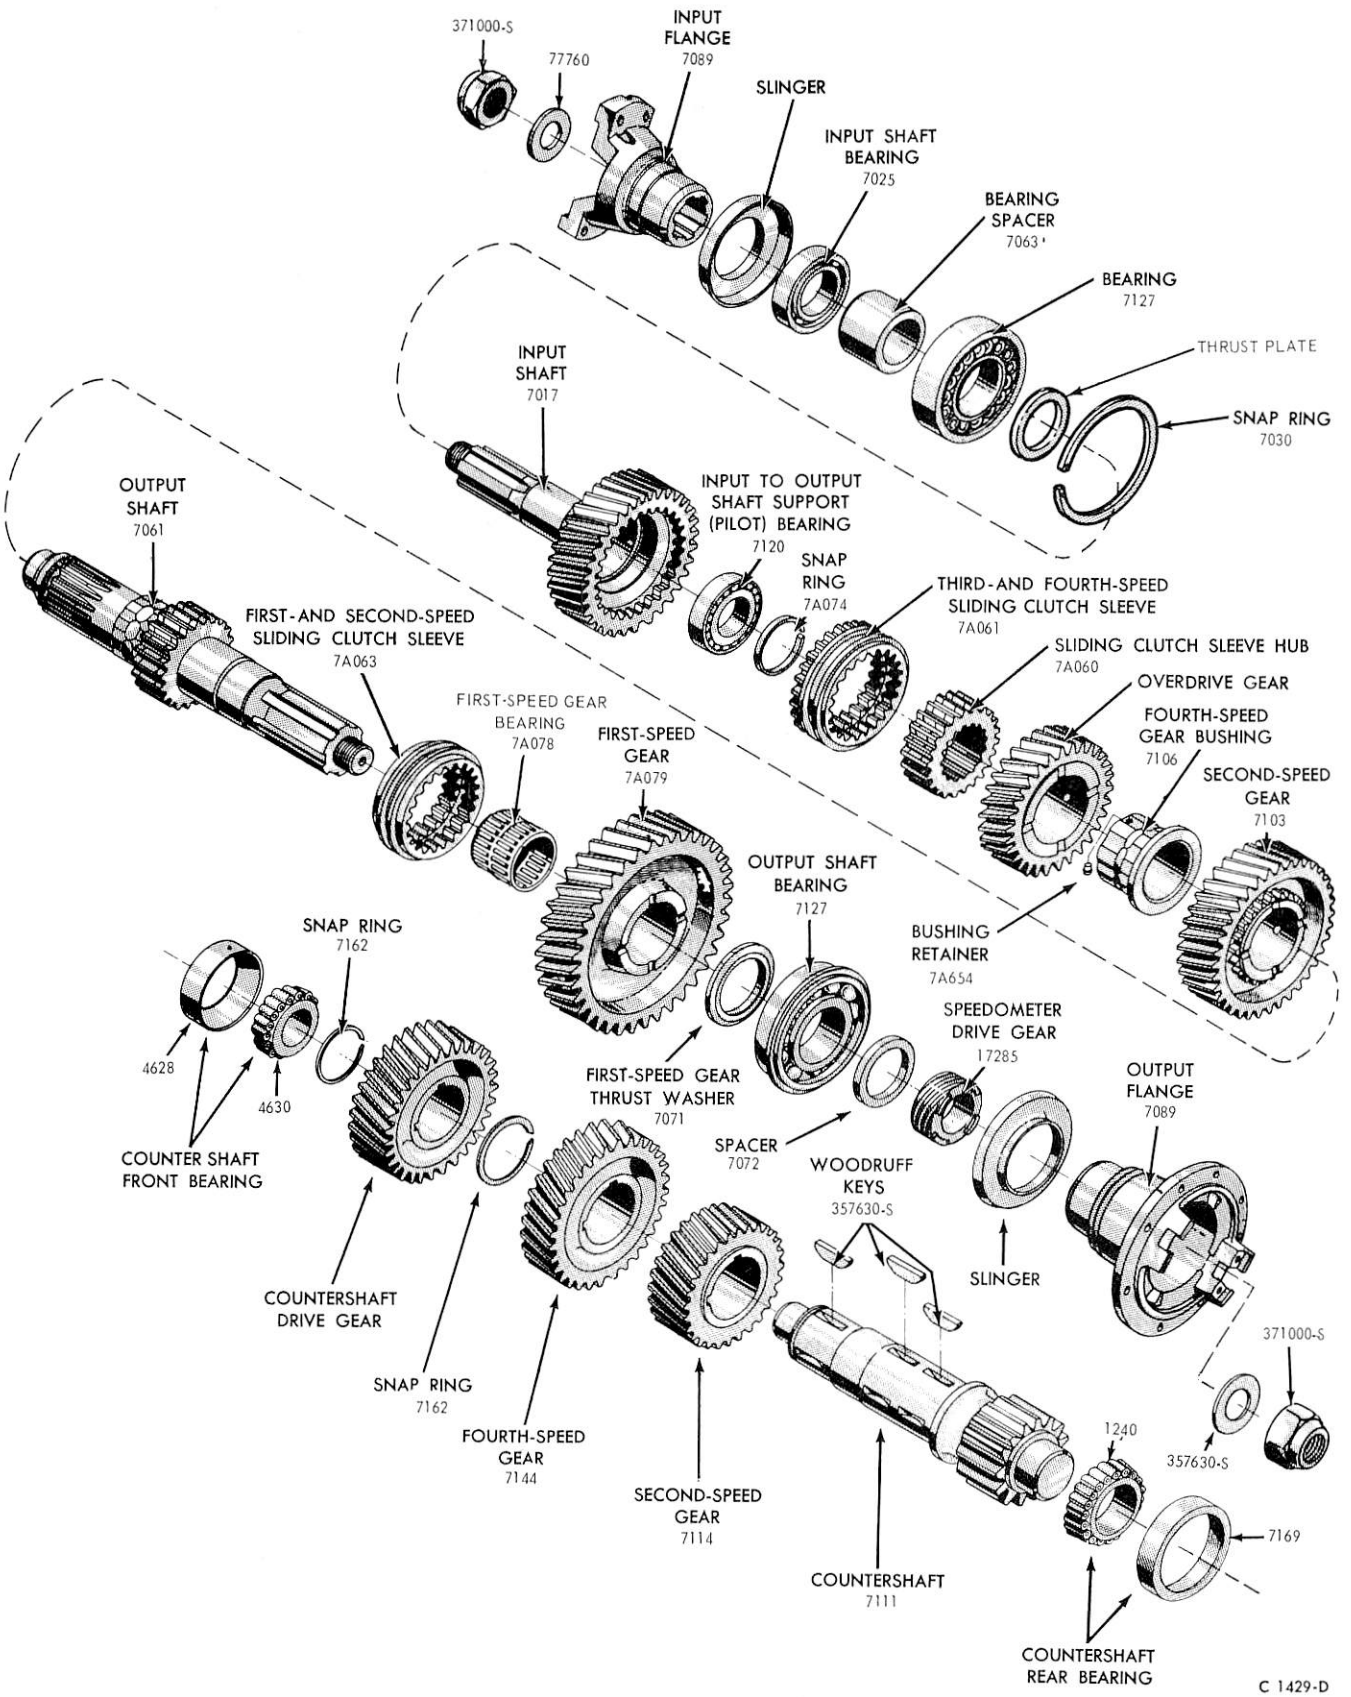

FIG. 29 Transmission Gear Train Disassembled—Model 7041

8. Install the speedometer gear spacer with the flat side to the rear and install the speedometer gear.
9. Install the output shaft bearing retainer and gasket.
10. Install the third and fourth-speed sliding clutch sleeve.
11. Install the pilot (pocket) bearing on the front of the output shaft.
12. Install the input shaft in the case and onto the pilot bearing.
13. Install the input shaft bearing retainer and gasket.
14. Install the input shaft bearing spacer, front bearing and seal in the bearing retainer.
15. Press the input shaft flange on the input shaft T. Torque the retainer nut to specifications. Install the cotter pin.
16. Press output shaft flange into position and install flat washer and retainer nut. Torque the nut to specifications. Install the cotter pin.
17. Start the first and second-speed shift rod into the case. Place the first and second-speed fork in position and push the rod through it.
18. Insert the interlock in the case. Move the first and second rod to its neutral position.
19. Place the third and fourth-speed fork into position and slide the shift rod through the fork. Move the rod to its neutral position.
20. Install the fork lock screws and the lock wire.
21. Install the detent balls, springs and spring retainers.
22. Install the top cover.

SUB-ASSEMBLIES

OUTPUT SHAFT

Disassembly

1. Slide the first-speed gear and bushing off the rear of the output shaft (Fig. 29).
2. Slide the first and second-speed sliding clutch sleeve off its hub and off the rear of the output shaft.
3. Remove the third and fourth-speed (or third and overdrive) sliding clutch sleeve hub snap ring from the front of the output shaft.
4. Remove the sleeve hub from the front of the output shaft.
5. Slide the third-speed (or overdrive) gear off the front of the output shaft.
6. Place the output shaft assembly in a press. Support the assembly on the outer rear face of the second-speed gear and press the output shaft through the third-speed (or overdrive) gear bushing and the second-speed gear. The bushing retainer will come off with the third-speed (or overdrive) gear bushing.

Assembly

1. Place the second-speed gear on the front of the output shaft with the clutch teeth toward the rear of the shaft (Fig. 29).
2. Install the retainer (Fig. 29) in the fourth-speed or (overdrive) gear bushing and press the bushing onto the output shaft. The flanged end of the bushing goes toward the rear of the output shaft.
3. Slide the fourth gear (or overdrive) gear on its bushing.
4. Install the third and fourth-speed (or overdrive) sliding clutch sleeve hub on the output shaft. Install the snap ring.
5. Install the first and second-speed sliding clutch sleeve over the rear of the output shaft and onto its hub which is integral with the shaft. The longer part of the hub (from the shift fork groove) goes toward the front of the input shaft.
6. Slide the first-speed gear onto the rear of the output shaft.

INPUT SHAFT

Disassembly

1. Press the input shaft through the input shaft front and rear bearings and out of the rear of the input shaft bearing housing.
2. The input shaft rear bearing and input shaft front-to-rear bearing spacer can be removed from the housing after the snap ring between the rear bearing outer race and housing has been removed.
3. Remove the input shaft front bearing and input shaft flange seal arm out through the front of the housing.
4. Remove the input-to-output shaft (pocket) bearing.

Assembly

1. Install the two-piece input shaft rear bearing into the input shaft bearing retainer housing with the thrust plate (Fig. 30) facing the rear. Assemble the flanged spacer with flanged end down toward the new bearing. (See stamped word 'FRONT' on sleeve.) Assemble small (front end) bearing into the bearing cap bore. Seat the bearing to cap shoulder firmly.

With tubing, or sleeve supporting the small bearing in the cap, place tubing and cap on the Arbor Press (with large rear bearing face up). Check the large bearing to be sure the thrust plate of bearing is still in proper place. Position the drive gear in the bearing cap sub-assembly and press the gear slowly into both bearings. Be sure proper seating between the thrust plate and drive gear shoulder is achieved as shown in Figure 30. (Fig. 30)

2. Install the snap ring in the housing rear of the bearing outer race.

COUNTERSHAFT

Disassembly

1. Remove the front and rear countershaft bearing cones with a suitable puller.
2. Remove the countershaft drive gear snap ring.
3. Place the countershaft assembly in a press. Support the drive gear at its hub or as near to the hub as possible. Press the countershaft out of the drive gear.
4. Remove the two exposed Woodruff keys from the countershaft and remove the fourth-speed (or overdrive) gear snap ring.
5. Place the countershaft assembly in a press. Support the assembly on the rear face of the fourth-speed (or overdrive) gear, and press the output shaft out of it.
6. Remove the exposed Woodruff keys.
7. Return the assembly to the press. Support the second-speed gear and press the countershaft out of it.
8. Remove the exposed Woodruff keys.

Assembly

1. **To assemble the countershaft, reverse the procedure given under Disassembly. Observe the following cautions:**
   a. Coat the bores of all gears with white lead before they are pressed on the countershaft.
   b. If the Woodruff keys are mutilated or burred after they are installed in the shaft, file the keys to the correct dimension and remove the burrs. This will prevent chips and slivers from peeling off during gear installation. These chips and slivers may prevent the next gear from seating properly.
   c. Most gear bores are chamfered only on the shaft-entering side. Press the shaft into the chamfered end of the gear bore.

MODEL 5831

Disassembly

1. Remove the gear shift housing and install the transmission assembly in an overhaul stand.
2. Lock the transmission in two gears, remove the input yoke nut, and remove the input shaft yoke and slinger.
3. Remove the transmission support

from the input shaft bearing retainer.
4. Remove the nut and flange (and drum) from the output shaft. Remove the brake shoe assembly.
5. Remove the attaching bolts from the transmission rear mounting bracket and remove the bracket.
6. Remove the output shaft rear bearing retainer bolts and lock washers. Remove the retainer and gasket, and remove the speedometer drive gear from the output shaft.
7. Remove the input shaft bearing retainer bolts and lock washers. Remove the retainer, the gasket, and the bearing spacer from the input shaft.
8. Remove the countershaft rear bearing cap and shims, and tie the shim pack together for use at assembly.
9. With a soft hammer, tap the underdrive gear toward the rear of the transmission until the bearing clears the case bearing bore.
10. Install a suitable two-jawed puller, and remove the bearing from the output shaft. Remove the underdrive sleeve and hub from the output shaft through the rear bearing bore (Fig. 31).
11. Tilt the front of the output shaft upward until it clears the input shaft, and slide the output shaft out of the case.
12. Remove the 13 pilot bearing rollers from the recess in the input shaft.
13. Remove the input shaft bearing snap ring from the bearing.
14. Tap the bearing and gear into the case with a brass hammer.
15. With a brass drift and hammer, drive the countershaft toward the rear of the case until the countershaft rear bearing cup is out of the case.
16. Slide the countershaft toward the rear of the case until it clears the bore in the case, and remove the shaft from the case. **Remove any output shaft pilot bearing rollers which may have dropped into the case.**
17. With a brass drift, remove the countershaft front bearing cup from the case.
18. If the input shaft bearing is to be removed, install Tool T53T-7065-A on the input shaft bearing, and remove the bearing from the input shaft. Remove the tool from the bearing.

Assembly

Coat all parts with transmission lubricant to prevent scoring when the transmission is first operated.

1. Position the transmission support, making certain the support does not bind and is free on the bearing retainer. **Install the support so that the face marked FRONT is forward.**
2. Make certain the U-joint flange and yoke hubs, which contact the lips of the oil seals, are clean, smooth, and free of corrosion. If there is corrosion or roughness and it cannot be removed with fine emery cloth, install a new U-joint flange and yoke. Coat the hub of the front flange with new transmission lubricant.
3. Lock the transmission in two gears. Install the slinger, the input shaft yoke, the input yoke nut, and torque the nut to specification. Lock the nut in place with a new cotter pin.
4. Press the input shaft bearing onto the input shaft with the snap ring groove toward the splined end of the shaft.
5. Insert the splined end of the input shaft into the input shaft bearing bore from inside the case. After the bearing is positioned in the bore, install the snap ring on the bearing making certain that the snap ring seats solidly in its groove.
6. Coat the input shaft pilot bearing recess with enough petrolatum to hold the pilot bearing rollers in place and position the 13 rollers in the recess.
7. Install a new input shaft bearing spacer over the outer end of the input shaft and against the inner bearing. Apply B5A-19554-A sealing compound to a new input shaft bearing retainer gasket and install the gasket on the front of the case. The gasket oil passage hole must be properly aligned.
8. Carefully position the bearing retainer over the end of the input shaft, and carefully tap the retainer into place. Install the retainer attaching bolts, using new lock washers, and torque the bolts to specifications. Install the transmission vent in the top of the bearing retainer.
9. Install the transmission mounting bracket and torque the mounting bracket bolts to specification.
10. Install the brake shoe assembly. Install the rear U-joint flange (and drum), and torque the nut to specification. Secure the nut with a new cotter pin.
11. Make sure the transmission gears are in neutral. Apply B5A-19554-A sealing compound to a new shift housing gasket and place the shift housing gasket on the transmission case.

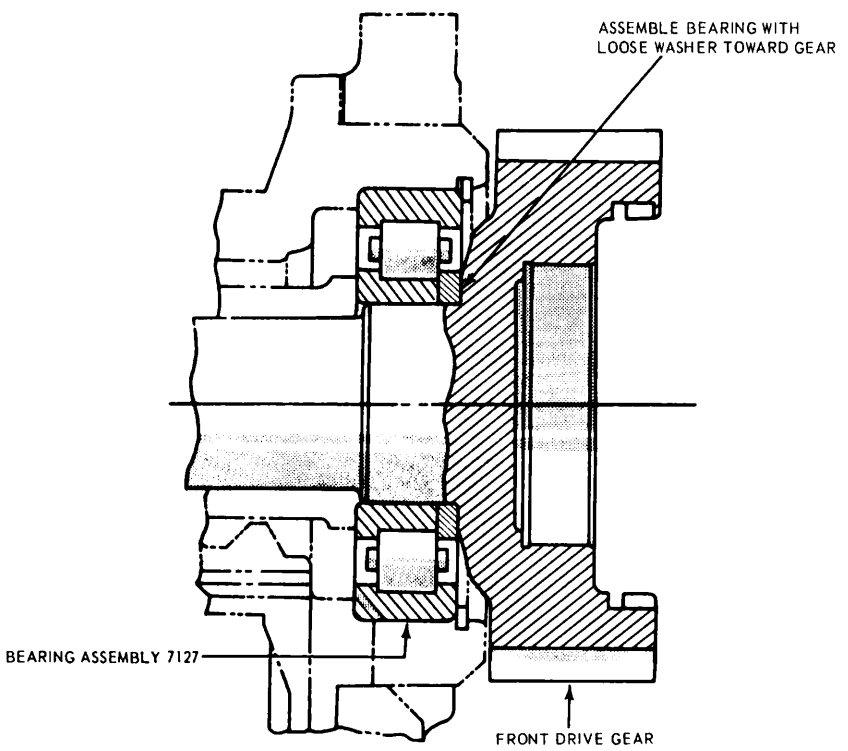

FIG. 30 Installing Input Shaft Rear Bearing—Model 7041

12. Position the housing on the gasket with the outer ends of the shift rods toward the front of the transmission and each shifter fork engaged in its respective sleeve groove. Install the housing on the case, and torque the bolts to specification.

SUB-ASSEMBLIES

OUTPUT SHAFT

Disassembly

1. Remove the underdrive gear from the output shaft.
2. Remove the direct and overdrive sleeve from the front end of the shaft.
3. From the front end of the output shaft, remove the snap ring that holds the hub in place. Remove the hub and the overdrive gear.

Assembly

1. Apply transmission lubricant to the shaft and gear splines. Position the output shaft overdrive gear on the front end of the shaft with the sleeve teeth toward the front (Fig. 30).
2. Position the output shaft direct and overdrive hub, with the face of the hub stamped X toward the front end of the shaft. Install the hub snap ring in its groove. **The snap ring must seat solidly in the groove.**
3. Coat the exterior teeth of the hub with new transmission lubricant and install the direct and overdrive sleeve on the hub with the external teeth on the hub of the sleeve toward the front end of the output shaft. Install the underdrive gear, with the sleeve teeth toward the rear.
4. Position the rear end of the output shaft and gear assembly in the rear bearing bore, and lower the output shaft into place. The output shaft overdrive and underdrive gear teeth must mesh with the respective countershaft gears.
5. Position the underdrive hub with the face stamped X toward the rear of the output shaft. Insert the hub through the output shaft bearing bore and against the face of the underdrive gear. Install the sleeve through the rear bearing bore with the long hub of the sleeve facing the underdrive gear (Fig. 31).
6. Position the output shaft rear bearing on the shaft, with the snap ring groove toward the rear of the transmission. Drive the bearing into place with a brass drift or with a steel tube which will bear on the

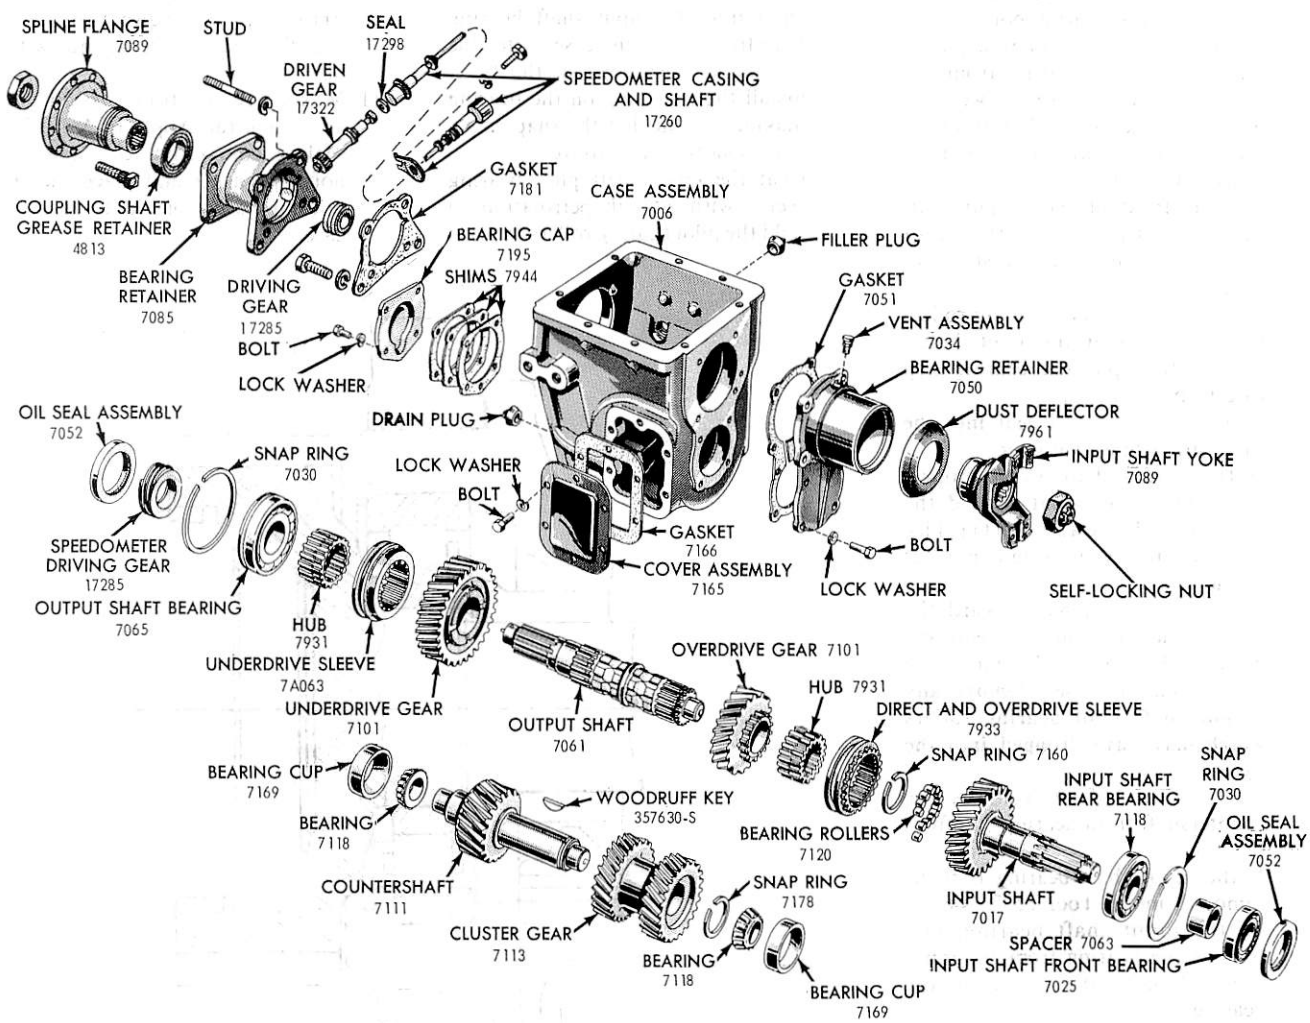

FIG. 31 Model 5831—Disassembled

bearing inner race. Install the snap ring in the bearing groove, seating the ring solidly.
7. Install the speedometer drive gear.
8. Apply B5A-19554-A sealing compound to the new output shaft rear bearing retainer gasket and position the output shaft rear bearing retainer gasket on the rear of the transmission.
9. Position the bearing retainer, and install the bolts and new lock washers. Torque the bolts to specification.
10. Install the power take-off covers on the transmission case, using new gaskets.

COUNTERSHAFT

Disassembly

1. Remove the countershaft drive gear snap ring from the groove in the shaft, leaving the ring on the shaft behind the bearing.
2. Position the countershaft in a press, and press the countershaft out of the front bearing, the snap ring, and the cluster gear.
3. Remove the countershaft rear bearing and remove the Woodruff key from the countershaft.

Assembly

1. Press the countershaft rear roller bearing onto the countershaft. Install the Woodruff key in the countershaft keyway.
2. Position the rear end of the countershaft in a press plate. Position the cluster gear on the countershaft aligning the gear keyway with the Woodruff key in the countershaft. The countershaft drive gear (the smaller cluster gear) must be toward the front.
3. Press the cluster gear onto the countershaft. Install the cluster gear snap ring.
4. Press the countershaft front roller bearing onto the countershaft. Lower the rear end of the countershaft, and slide the assembly forward into position.
5. Brush a thin coating of transmission lubricant onto the inner faces of the countershaft bearing cups. Position a cup in the countershaft bearing retainer, with a new retainer gasket to properly locate the countershaft front roller bearing cup.
6. Position the countershaft rear bearing cap without shims, and install the bolts.

Measure the clearance between the cap and case. Select a shim or shims which will permit the countershaft to have a 0.001 to 0.003 inch end play. Shims are available in the following sizes: 0.003, 0.010, and 0.030 inch.

After the countershaft bearing adjustment is completed, torque the bolts to specification.

BEARING RETAINERS

Disassembly

Press the oil seal and bearing out of the input shaft bearing retainer, and remove the vent. Press the seal out of the output shaft rear bearing retainer.

1. Press the input shaft outer bearing squarely into the input shaft bearing retainer. Apply B5A-19554-A sealing compound to the OD of a new input shaft oil seal and install the oil seal. The wiping lip of the seal must be positioned toward the rear of the retainer.
2. Apply B5A-19554-A sealing compound to the OD of a new output shaft oil seal and install the oil seal in the output shaft rear bearing retainer, with the wiping lip of the oil seal toward the front of the transmission.

GEAR SHIFT HOUSING

Disassembly

1. Remove the shift rod spring and ball plug from the side of the housing, and remove the spring and ball (Fig. 32).
2. Remove the lock wire and set screw from the direct and overdrive shifter fork. Slide the direct and overdrive shift rod out of the front of the housing, and remove the shifter fork. Remove the plunger from the housing.
3. Remove the lock wire and set screw from the underdrive shifter fork. Pull the underdrive shift rod out of the shifter fork. Remove the ball and spring from the housing.
4. If the oil seals in the front of the housing are damaged, or cause oil leaks, remove the seals from the cover.

Assembly

1. Place the housing in a vise, with the plunger spring and ball opening in the housing at the top. Dip the spring in transmission lubricant, and position it in the housing (Fig. 32).
2. Place one of the shift rod balls on top of the spring. Insert the underdrive shift rod (longer shaft) through the front of the housing. Hold the ball down, and push the shift rod through the center support. The notches in the rod must be indexed with the ball.
3. Pull the shift rod back far enough to permit installation of the underdrive shifter fork. Install the fork on the shaft **with the longer hub of the fork toward the front of the housing.** Align the lock screw hole in the fork with the lock screw recess in the shift rod.

Install the lock screw, tighten it solidly, and install a new lock wire. Shift the rod and fork assembly to neutral position.

4. Insert the plunger in the cross hole in the cover. Insert the direct and overdrive shift rod into the housing. Position the direct and overdrive shifter fork on the rod, and slide the rod through the center support. Align the lock screw hole in the rod, install the lock screw, and tighten it firmly. Secure the lock screw with a new lock wire.
5. Install the shift rod ball, dip the spring in new transmission lubricant, and position the spring on top of the ball. Secure the spring with the retaining plug. Tighten the plug solidly.
6. If the housing shifter shaft oil seals were removed, place the new oil seals (dipped in transmission lubricant), over the front ends of the two shifter shafts with the lips of the seals toward the rear of the cover. Press them carefully into place. The lips of the seals must not be damaged during installation. Shift the direct and overdrive shifter shaft and fork assembly to the neutral position.

DESCRIPTION

TRANSFER CASE

A manually-shifted 2-speed transfer case in the 4-wheel drive Bronco transfers the power from the engine and transmission to the front and rear driving axles. The transfer case shift lever positions, from front to rear, are 4L (low gear, all wheels), N (Neutral), 2H (high gear, rear wheels), and 4H (high gear, all wheels).

REMOVAL AND INSTALLATION

TRANSFER CASE

Removal

1. Shift the transfer case into neutral.
2. Remove the bolts attaching the fan shroud to the radiator support.
3. Raise the vehicle on a hoist.
4. Support the transfer case shield with a jack and remove the bolts that attach the shield to the frame side rails. Remove the shield.
5. Drain the transmission and transfer case lubricant.
6. Disconnect the front and rear drive shafts at the transfer case (Fig. 1).
7. Disconnect the speedometer cable at the transfer case.
8. If equipped with a manual transmission, disconnect the shift rods from the transmission shift levers. Then, place the first-reverse gear shift lever into the first gear position, and insert the fabricated tool (Fig. 2). This tool will prevent the input shaft roller bearings from dropping into the transmission case when separating the transfer case from the transmission and output shaft.
9. Support the engine with a jack.
10. Remove the two cotter pins, bolts, washers, plates, and insulators that secure the crossmember to the transfer case adapter.
11. Remove the crossmember to frame side support attaching bolts.
12. Raise the transmission and remove the upper insulators from the crossmember, remove the crossmember.
13. Roll back the boot enclosing the transfer case shift linkage. Remove the threaded cap holding the shift lever assembly to the shift bracket. **Remove the shift lever assembly.**
14. Secure the transfer case to a transmission jack, and remove the transfer case adapter-to-transmission attaching bolts.
15. Move the transfer case and jack rearward until it clears the transmission output shaft. Lower the transfer case.

Installation

1. Position the transfer case to the transmission and install the attaching bolts. Torque the bolts to specifications (Fig. 1).
2. Position the transfer case shift lever and install the threaded cap to the shift bracket. Reposition the rubber boot.
3. Raise the transmission and transfer case high enough to provide

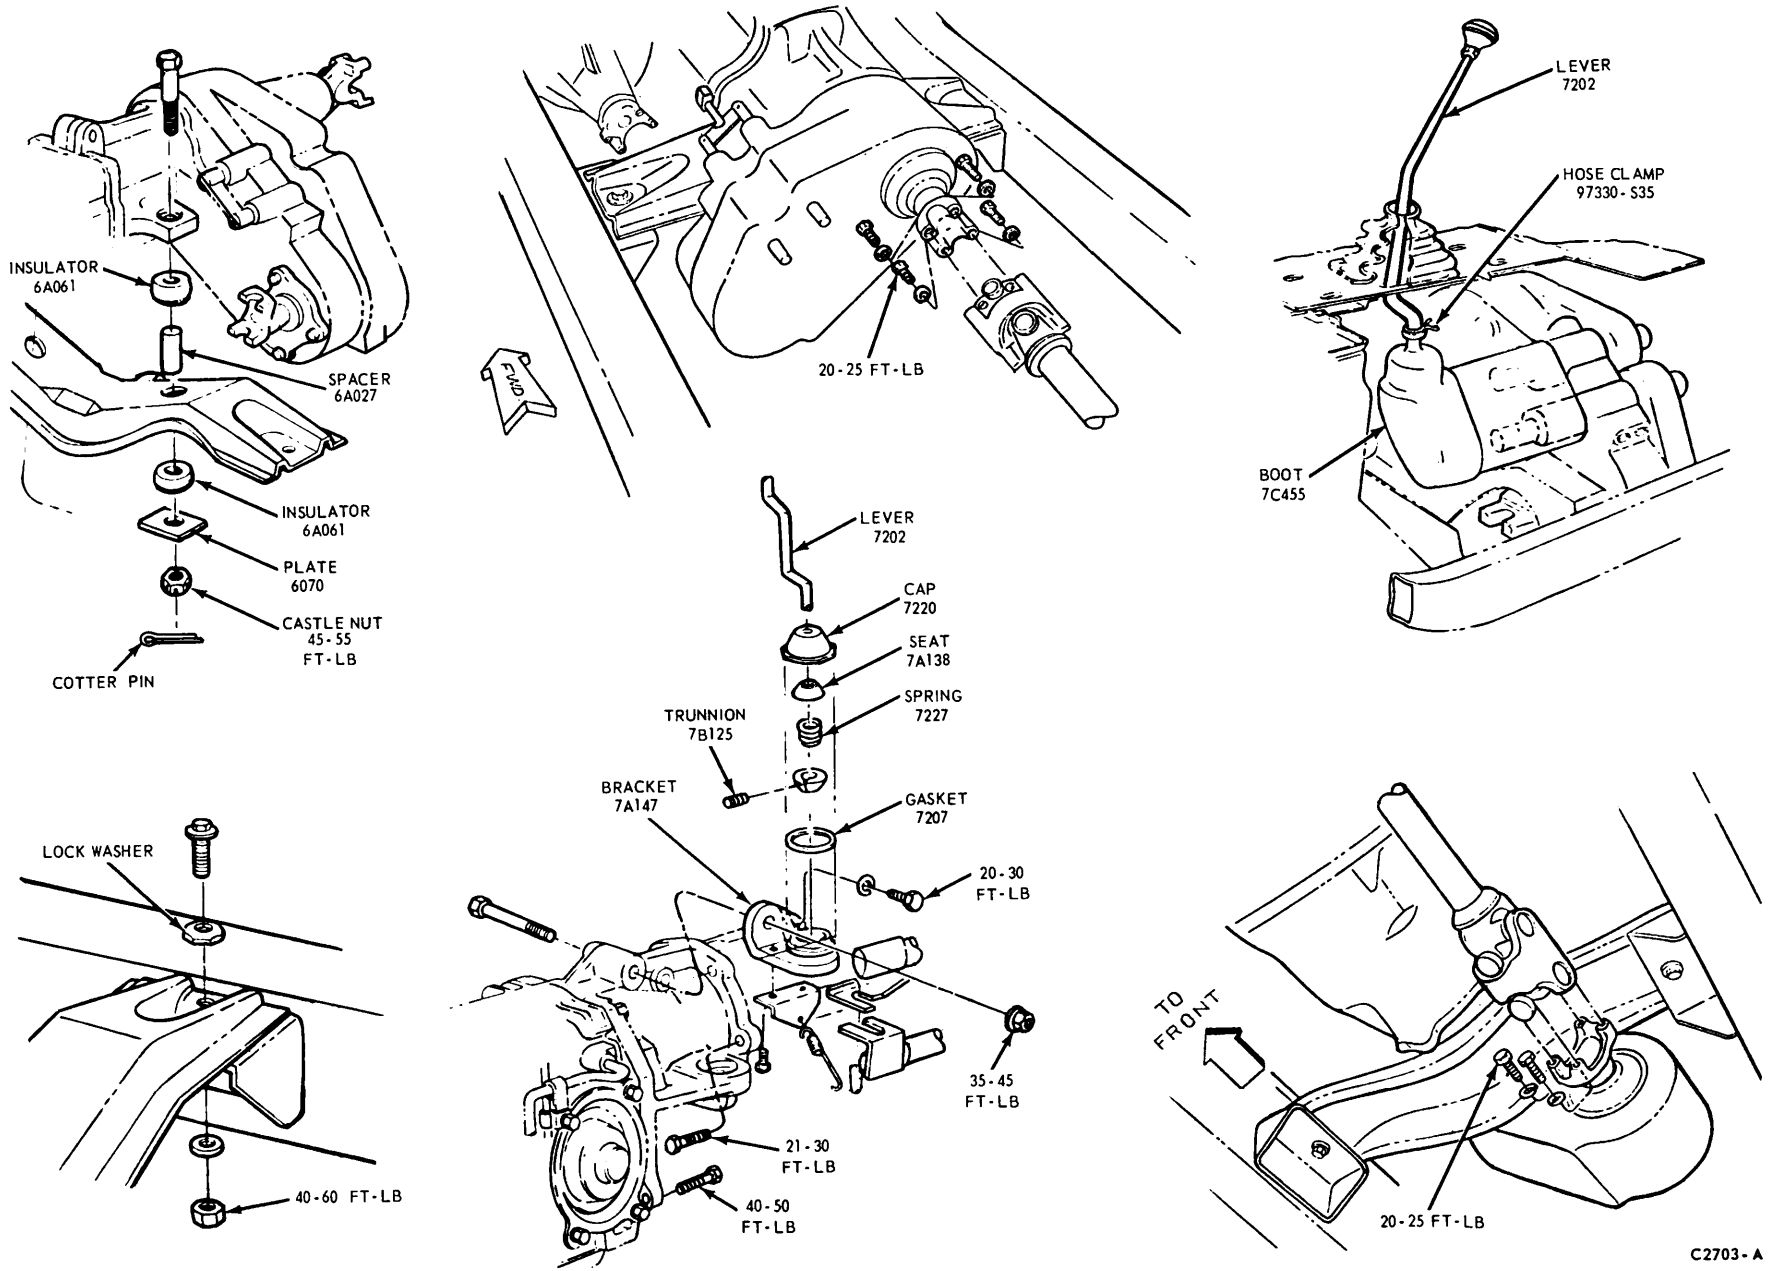

FIG. 1 Transfer Case Installation

clearance for installing the crossmember. Position the upper insulators to the crossmember and install the crossmember-to-frame side support attaching bolts. (Torque to specifications Fig. 1).

4. Align the bolt holes in the transfer case adapter with those in the crossmember, then lower the transmission and remove the jack.
5. Install the crossmember-to-transfer case adapter bolts, insulators, plates, and washers. Torque the bolts to specifications (Fig. 1). Secure the bolts with cotter pins.
6. Remove the engine jack.
7. If equipped with a manual transmission, remove the fabricated tool (Fig. 2), and connect each shift rod to its respective lever on the transmission. Refer to Part 16-11 for rod adjustment instructions.
8. Connect the speedometer cable.
9. Install the rear axle driveshaft to the transfer case, and torque the attaching bolts to specifications.
10. Install the front wheel driveshaft to the transfer case, and torque the attaching bolts to specifications.
11. Fill the transmission and transfer case to the proper levels with the recommended lubricant.
12. Position the transfer case shield to the frame side rails, and install the attaching bolts.
13. Lower the vehicle.
14. Install the fan shroud.
15. Check transfer case operation.

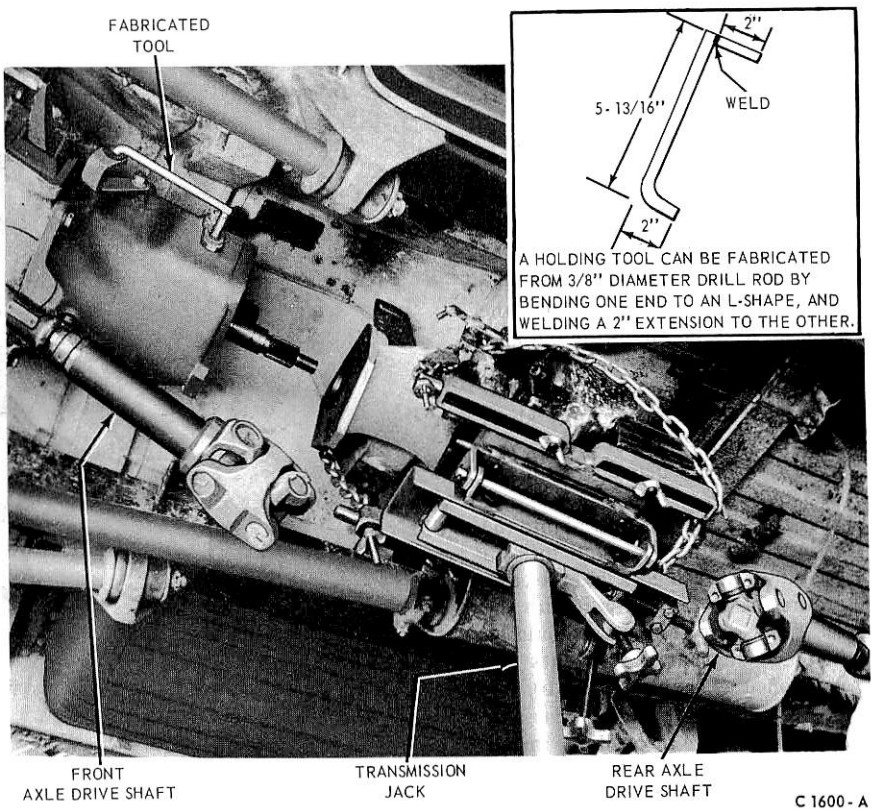

FIG. 2 Removing or Installing Transfer Case—Bronco-Manual Transmission

DISASSEMBLY AND ASSEMBLY

TRANSFER CASE

Disassembly

1. Clean the dirt from the transfer case, and remove the bottom cover plate.
2. Remove the retaining plug, flat washer, detent spring, and ball that engages the front drive shaft rail detent rod. Then, remove the plug from the front drive detent rod access hole (Fig. 3).
3. Remove the retaining plug, detent spring, and ball that engages the rear drive shift rail detent rod (Fig. 3).
4. Remove the idler shaft lock plate from the rear of the case.
5. **Using a hammer and soft drift, drive the idler shaft rearward and out of the case. Then, lift the thrust washers and idler gear from the case (Fig. 3). When removing the idler gear, do not lose any of the rollers.**
6. Remove the flange retaining nuts from the front and rear output shafts (Fig. 5).
7. Remove the flange from the front and rear output shafts (Fig. 6). Discard the front flange O-ring.
8. Remove the bolts securing the adapter housing to the case and remove the adapter as an assembly (Fig. 7).
9. Remove the bolts that attach the rear output shaft bearing retainer to the case, and remove the retainer and output shaft as an assembly. **Be careful not to lose any of the rollers.**
10. Disconnect the shift rail link from the two shift rails.
11. Lift the rear output shaft sliding gear from the case (Fig. 7).
12. Remove the set screw securing the rear shift fork to the shift fork to the shift rail. Then, remove the rear drive shift rail and fork from the case (Fig. 7).
13. Remove the front output shaft rear cover and shims. Tie the shims together.
14. Remove the front output shaft bearing retainer and gasket. Remove the retainer seal if it is worn or damaged.
15. Tap the threaded end of the front output shaft to remove the rear cup from the case bore.
16. Wedge the front output shaft front bearing away from the main drive gear to allow removal of the snap ring from its groove in the shaft. Then, tap the shaft and rear bearing out of the case (Fig. 8).
17. Lift the sliding gear, main drive gear, front bearing, spacer, and snap ring from the case.
18. Remove the front cup from the case

bore.

19. Remove the set screw securing the front shift fork to the shift rail. Then, remove the shift rail and fork from the case.
20. Remove the detent rods (Fig. 9).

Assembly

1. Install the front detent rod in the case.
2. Slide the front drive shift rail all the way into the case, and position the shift fork on the rail as the rail goes into the case. Secure the fork to the rail with the set screw.
3. Position the front output shaft sliding gear in the shift fork.
4. Install the rear detent rod in the case.
5. Slide the rear drive shift rail into the case, and position the shift fork on the rail as the rail goes into the case. Secure the fork to the rail with the set screw. **The shift rails should be inserted so that the detents are positioned as shown in Fig. 10.**
6. **While holding the sliding gear and main drive gear in position, install the front output shaft and rear bearing assembly through the two gears from the rear of the case.**
7. Install the main drive gear spacer and secure with the snap ring (Fig. 11).
8. Install the front output shaft rear bearing cup.
9. Position the front output shaft rear cover and shims to the case, and install the attaching bolts.
10. Using front flange and the tool shown in Fig. 4, install the front output shaft front bearing on the shaft. Install the front bearing cup (Fig. 11).
11. **If the front bearing retainer oil seal was removed, install a new seal using Tool T57-L7657. Position the bearing retainer and gasket to the case, and install the attaching bolts.**
12. Place the rear output shaft rear bearing retainer on a work bench, and install 13 needle bearings in the splined hub of the output shaft with vaseline or grease.
13. Position the rear output shaft rear bearing retainer assembly to the case and install the attaching bolts.
14. Install the rear output shaft sliding gear in the shifting fork and on the splines of the output shaft.
15. Position the adapter housing assembly to the rear output shaft and case. Install the attaching bolts (Fig. 7).
16. Install the roller bearings in the bore of the idler shaft gear with vaseline or grease.

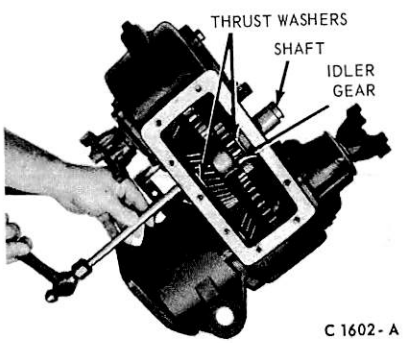

FIG. 4 Removing Idler Shaft

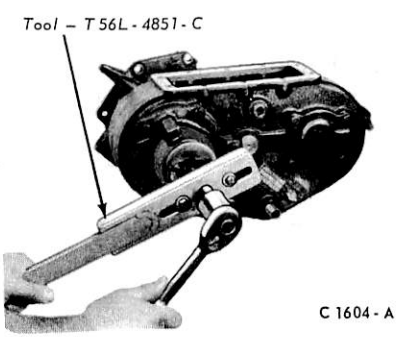

FIG. 6 Removing Flange

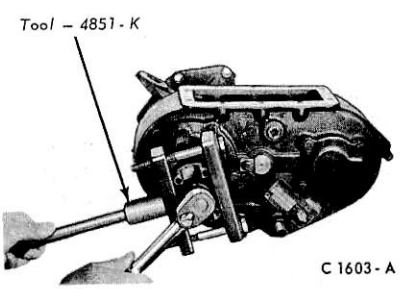

FIG. 5 Removing or Installing Flange Retaining Nut

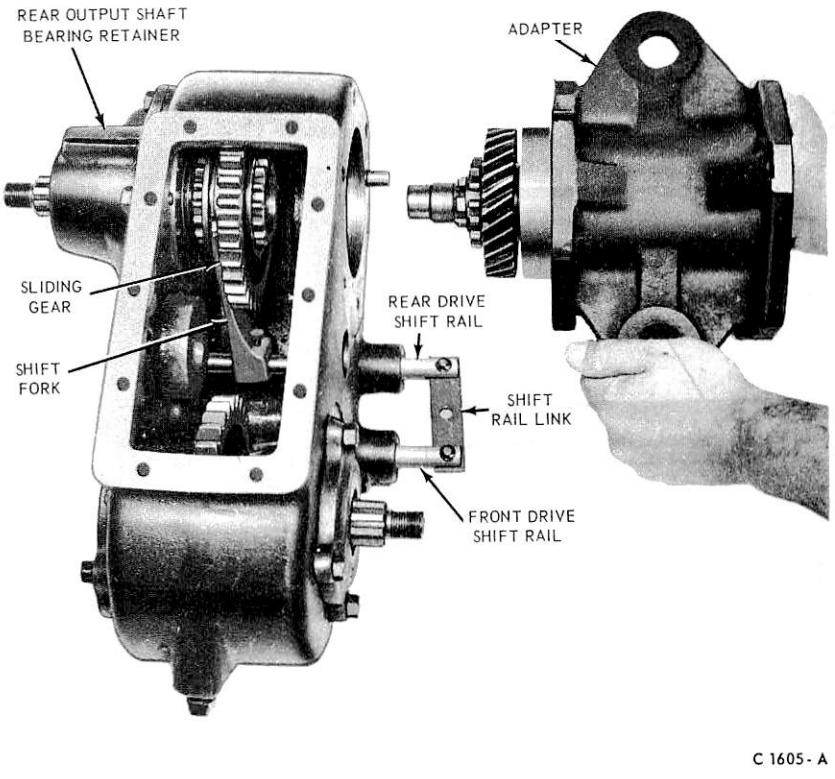

FIG. 7 Removing or Installing Adapter Housing

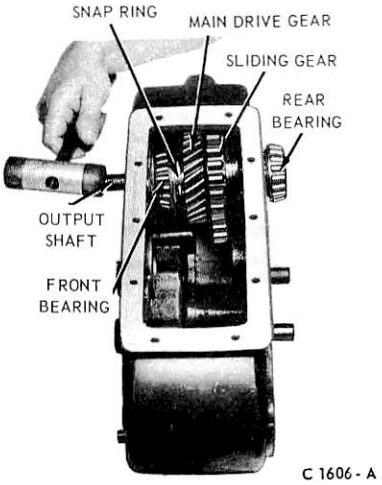

FIG. 8 Removing Front Output Shaft

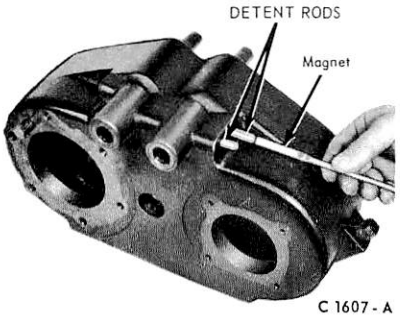

FIG. 9 Removing Detent Rods

17. Position the idler gear and thrust washers in the case, and drive the idler shaft into the rear of the case through the idler gear and thrust washers. **After installing the idler shaft, tap the sides of the case to relieve tension from the case.** Install the idler shaft lock plate.
18. Secure the shift rail link to the two shift rails.
19. Install the front and rear drive shift rail detent balls, springs, and retaining plugs. **Be sure that the heavier loaded spring and flat washer are installed in the front drive shift rail. Install the rod access hole plug.**
20. Install the flange, washer, and retaining nut on each of the output shafts, using the tool shown in Fig. 4. **Be sure to install a new O-ring in the front output shaft flange.** Torque the attaching nuts to specifications.
21. Install a dial indicator on the front drive output shaft and check the end play as shown in Fig. 11. The end play should be 0.001-0.005 inch. If not within these limits, adjust the shim pack at the front output shaft rear cover.
22. Position the cover plate to the case and install the attaching bolts.

SUB-ASSEMBLIES

INPUT SHAFT

Disassembly

1. Remove the snap ring from the front of the shaft (Fig. 13).
2. Place the adpater housing and input shaft on a press, and press the shaft out of the main drive gear and housing.
3. Remove the bearing retaining snap ring from the housing bore, and remove the bearing.
4. Remove the seal in the adapter housing if it is worn or damaged.

Assembly

1. If the adapter housing seal was removed, install a new seal with the tool shown in Fig. 14.
2. Place the bearing in the housing and secure with the snap ring.
3. Using the main drive gear as a base, press the input shaft through the housing seal, bearings, and main drive gear. Install the snap ring on the front of the shaft.

REAR DRIVE OUTPUT SHAFT

Disassembly

1. Remove the needle bearings from the bore of the shaft (Fig. 15).
2. Remove the speedometer driven gear from the bearing retainer housing.
3. Place the bearing retainer and rear output shaft assembly in a press, and press the shaft out of the retainer.
4. Lift the speedometer drive gear and shims from the shaft (Fig. 15). Tie the shims together.
5. Press the outer cup, bearing and seal from the bearing retainer as shown in Fig. 16.
6. Remove the inner cup with the tool shown in Fig. 16.
7. Remove the inner bearing from the output shaft with the tool shown in Fig. 17.

Assembly

1. Press the shaft onto the inner bearing with the tool shown in Fig. 17.
2. Install the outer cup in the bearing retainer with tool T55P-4616A1.
3. Install the inner cup with tool T56T-4616-A2.
4. Position the outer bearing into the bearing retainer. Then, place the

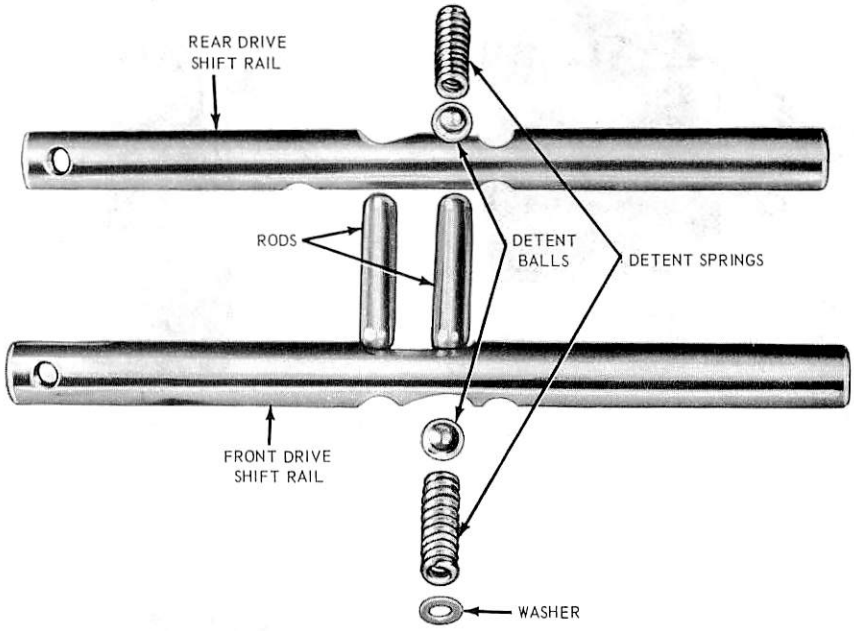

FIG. 10 Shift Mechanism

shims and speedometer drive gear on the output shaft, and install the shaft in the bearing retainer housing.

5. Place the bearing retainer and shaft in a vise. Install the output shaft flange and torque the attaching nut to specifications. Install a dial indicator on the flange end of the output shaft, and check the end play. The end play should be 0.003-0.005 inch. If not within these limits, adjust the shim pack (Fig. 15) between the speedometer drive gear and rear output shaft outer bearing.
6. After establishing the correct end play, remove the output shaft flange and press the bearing retainer seal in the housing with tool T56T-4616-A. Install the speedometer driven gear.

FRONT DRIVE OUTPUT SHAFT

Disassembly

1. To remove the front output shaft rear bearing, use the sliding gear as a base and press the bearing from the shaft.

Assembly

1. Install the bearing as shown in Fig. 18.

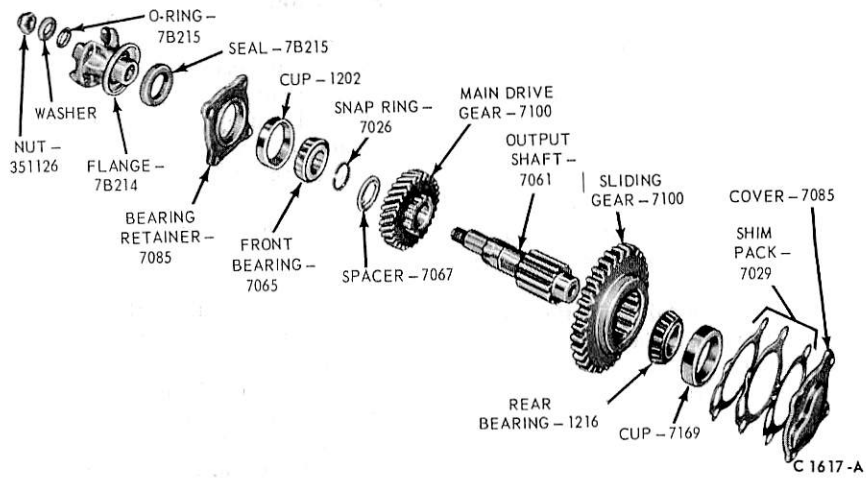

FIG. 11 Front Output Shaft—Disassembled

SHIFT RAIL OIL SEALS

Disassembly

1. Remove the shift rail seals as shown in Fig. 19.

Assembly

1. Install the two shift rail oil seals, using the tool shown in Fig. 20.

DESCRIPTION

TRANSFER CASE

A manually shifted single-speed transfer case in the F-100 4 x 4 transmits the power from the engine and transmission to the front and rear axles. There are two positions for the transfer case; front axle drive engaged and front axle drive disengaged (Fig. 1).

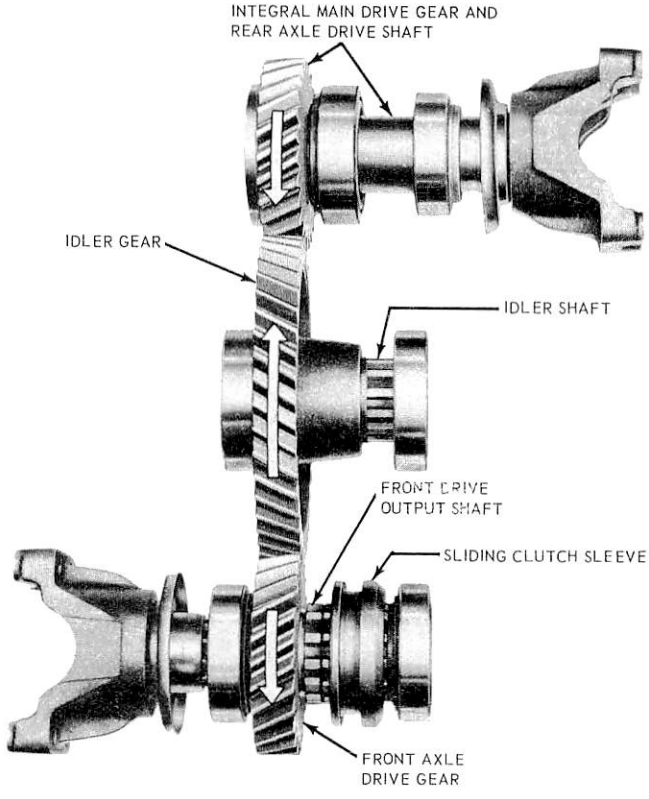

FIG. 1 Transfer Case Gear Train

REMOVAL AND INSTALLATION

TRANSFER CASE

Removal

1. Raise the vehicle on a hoist.
2. Disconnect the front and rear drive shafts at the transfer case.
3. Disconnect the shift rod from the transfer case shift lever arm.
4. Remove the bolts and nuts that attach the transfer case to the transmission extension housing, and remove the transfer case from under the vehicle.

Installation

1. Using a new gasket, position the transfer case to the extension housing and install the attaching bolts and nuts.
2. Connect the shift rod to the shift lever arm and secure with the spring washer, flat washer, and cotter pin.
3. Connect the front wheel drive shaft to the transfer case, and torque the bolts to specifications.
4. Connect the rear axle drive shaft to the transfer case, and torque the bolts to specifications.
5. Lower the vehicle and check for proper shift operation.

DISASSEMBLY AND ASSEMBLY

TRANSFER CASE

Disassembly

1. Clean the dirt from the transfer case and drain the lubricant.
2. Remove the bolts that attach the cover to the top of the case, and remove the cover (Fig. 2).
3. Remove the set screw securing the shift fork to the shift rail. Slide the shift rail out of the case.
4. Remove the shift fork from the case.
5. Remove the detent spring and ball that engages the front drive shift rail.
6. Remove the flange attaching nuts, flat washer, and O-ring from the front and rear output shafts. Discard the O-rings.
7. Remove the flange from the front and rear output shafts (Fig. 3).
8. Remove the bolts that attach the rear output shaft bearing retainer to the case, and remove the retainer and output shaft as an assembly.
9. Remove the front and rear idler shaft covers.
10. Using a hammer and soft drift, drive the idler shaft and rear idler bearing rearward and out of the case (Fig. 4). Then, lift the front bearing and idler gear from the case.
11. Remove the front output shaft bearing retainer and gasket. Remove the retainer seal if it is worn or damaged.
12. Remove the front output shaft rear cover and shims. Tie the shims together.
13. Tap the end of the front output shaft toward the front of the case to remove the front bearing cup. Remove the rear bearing cup by tapping the front output shaft rearward.

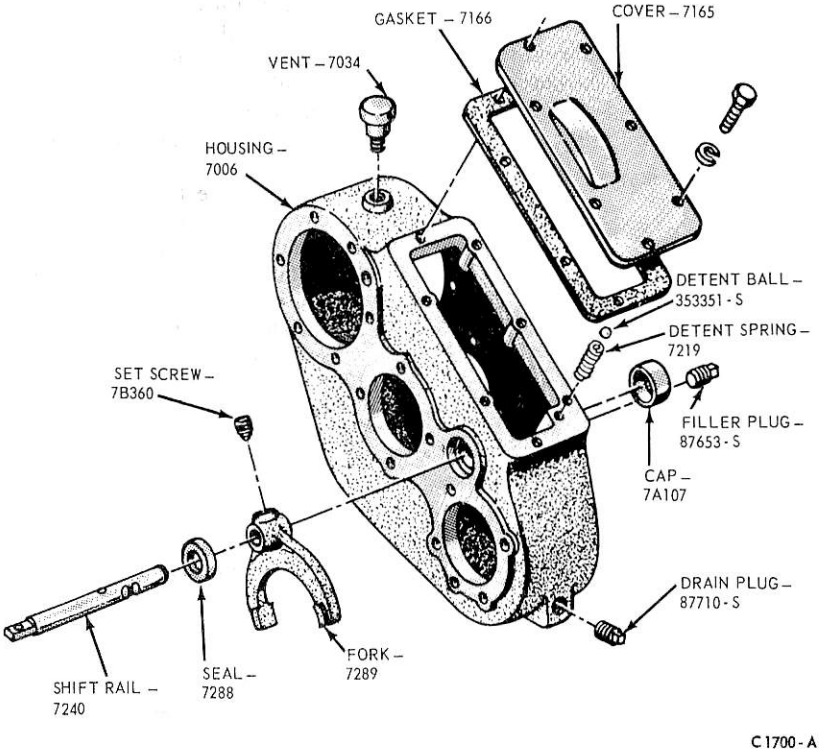

FIG. 2 Transfer Case Housing and Related Parts

14. Wedge the front output shaft front bearing away from the main drive gear to allow removal of the snap ring from its groove in the shaft. Then, drive the output shaft and rear bearing out of the case.
15. Lift the sliding gear, main drive gear, front bearing, thrust washer, and snap ring from the case.
16. Remove the shift rail seal from the case if it is worn or damaged.

Assembly

1. While holding the drive gear, sliding gear and thrust washer in the case, install the frontput shaft through the gears and washer from the rear of the case (Fig. 5). Install the snap ring.
2. Install the front output shaft rear bearing cup.
3. Position the front output shaft rear cover and shims to the case. After

removing old sealant from all parting surfaces with lacquer thinner, apply gasket sealer C6TZ-19554-A to the attaching bolts and torque to specifications. With the cover installed, apply gasket sealer C6TZ-19554-A to the outside edge of the adjusting shims, case and cover parting lines.

4. Using Tool T55P-7567-A, install the front output shaft front bearing on the shaft. Install the front bearig the shaft. Install the front bearing (Fig. 5).
5. If the front bearing retainer oil seal was removed, install a new seal using Tool T60K-7657-B. Position the bearing retainer and gasket to the case, and install the attaching bolts.
6. Install the flange, O-ring washer, and attaching nut on the front output shaft, using Tool T57T-4851-B. Be sure a new O-ring is installed on the shaft.
7. Install a dial indicator on the front drive output shaft and check the end play as shown in Fig. 6. The end play should be 0.003-0.005 inch. If not within these limits, increase or decrease the shim pack thickness at the front output shaft rear cover.
8. Position the idler gear in the case, and install the idler shaft through the gear. Install the front bearing on the shaft.
9. Position the front and rear idler covers and gaskets to the case, and install the attaching bolts.
10. Install a new shift rail seal in the case if it was removed.
11. Install the shift rail detent ball and spring in the top of the case.
12. Slide the shift rail into the front of the case, and position the shift fork on the rail as the rail enters the case. Depressing the detent ball and spring will allow the rail to pass. Secure the fork to the rail with the set screw.
13. Position the rear output shaft and bearing retainer assembly to the case, and install the attaching bolts.
14. Install the flange, O-ring, washer, and attaching nut on the rear output shaft, using Tool T58T-4851. Be sure a new O-ring is installed on the shaft.
15. Position the top cover and gasket to the case and install the attaching bolts.
16. Fill the transfer case to the proper level with the recommended lubricant.

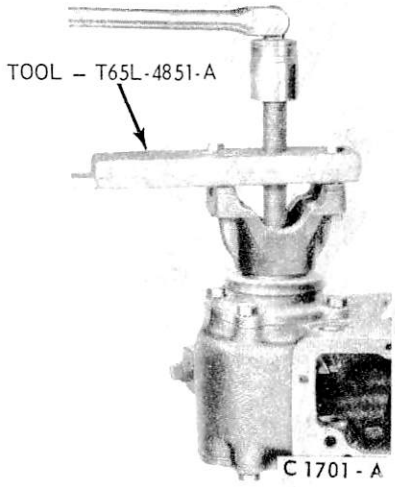

FIG. 3 Removing Flange

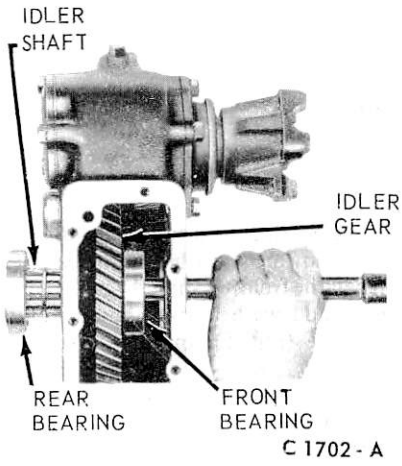

FIG. 4 Removing Idler Shaft

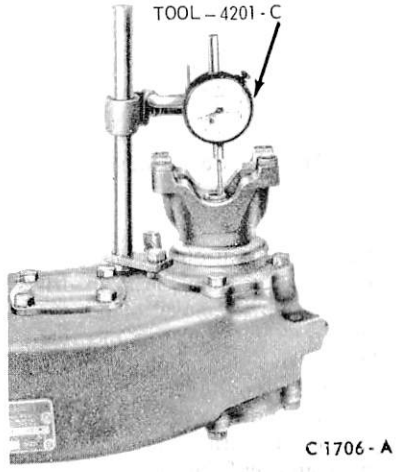

FIG. 6 Checking Front Drive Output Shaft End Play

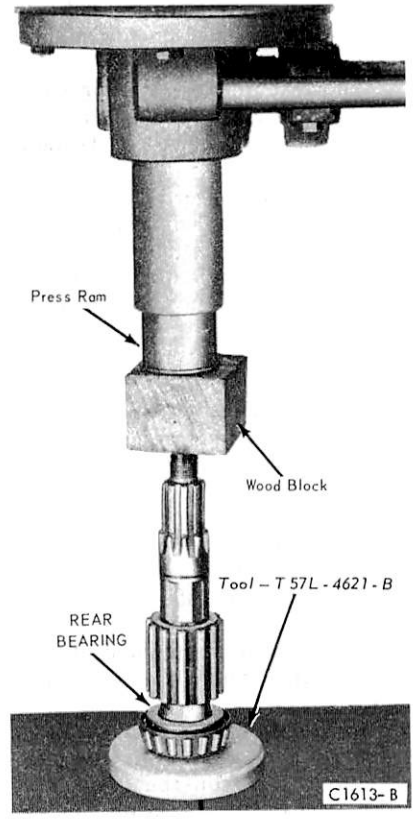

FIG. 7 Installing Front Output Shaft Rear Bearing

SUB-ASSEMBLIES

FRONT DRIVE OUTPUT SHAFT BEARING

Removal

1. To remove the front output shaft rear bearing, use the sliding gear as a base and press the bearing from the shaft.

Installation

1. Install the bearing as shown in Fig. 7.

IDLER SHAFT BEARING

Removal

1. Remove the snap ring from the idler shaft (Fig. 8).
2. Using the idler gear as a base, press the idler shaft out of the rear bearing.

Installation

1. Using a press, install the rear idler bearing on the idler shaft. Install the snap ring.

REAR DRIVE OUTPUT SHAFT BEARINGS

Removal

1. Tap the output shaft rearward to remove the shaft from the bearing retainer. Remove the shims and spacer from the shaft (Fig. 9).
2. Using Tool OTC-951, remove the inner bearing from the output shaft.
3. Place the bearing retainer on a press, and press out the outer cup, outer bearing, and oil seal using Tool T57T-7003-A.
4. Using a soft drift, drive the inner bearing cup from the retainer.

Installation

1. Press the inner bearing on the output shaft with Tool T53T-4621-B.
2. Using a soft hammer, tap the inner bearing cup into the bearing retainer.
3. Install the outer cup with Tool T60K-7657-B.
4. Place the spacer and shims on the output shaft and install the shaft in the bearing retainer housing.

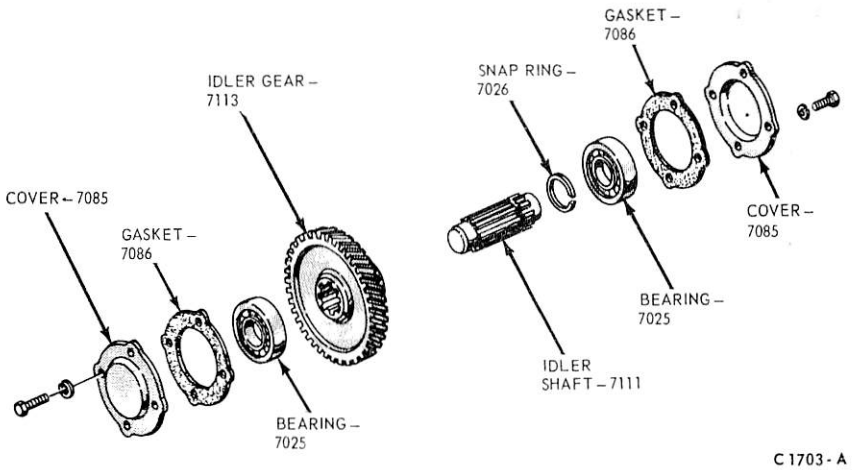

FIG. 8 Idler Shaft—Disassembled

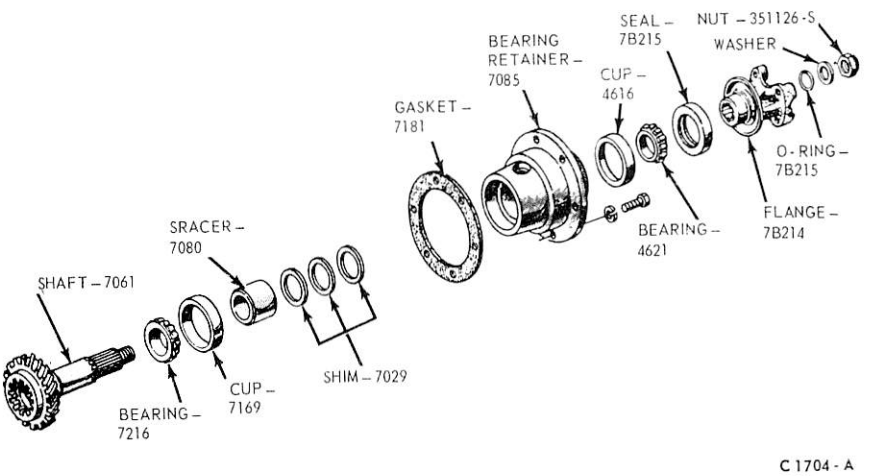

FIG. 9 Rear Drive Output Shaft—Disassembled

5. Install the outer bearing on the output shaft with Tool T55P-7657-A.
6. Place the bearing retainer and output shaft in a vise. Install a dial indicator on the end of the output shaft, and check the end play. The end play should be 0.003-0.005 inch. If not within these limits, adjust the shim pack (Fig. 4) between the spacer and the front and rear bearing cones.
7. After establishing the correct end play, install the bearing retainer seal in the housing with Tool T53T-7065-B.

DESCRIPTION

TRANSFER CASE

A manually-shifted 2-speed transfer case in the 4-Wheel Drive F-250 controls the power from the engine and transmission to the front and rear driving axles (Fig. 1). The transfer case shift lever positions, from front to rear, are 4L (low gear, all wheels), N (neutral), 2H (high gear, rear wheels), and 4H (high gear, all wheels).

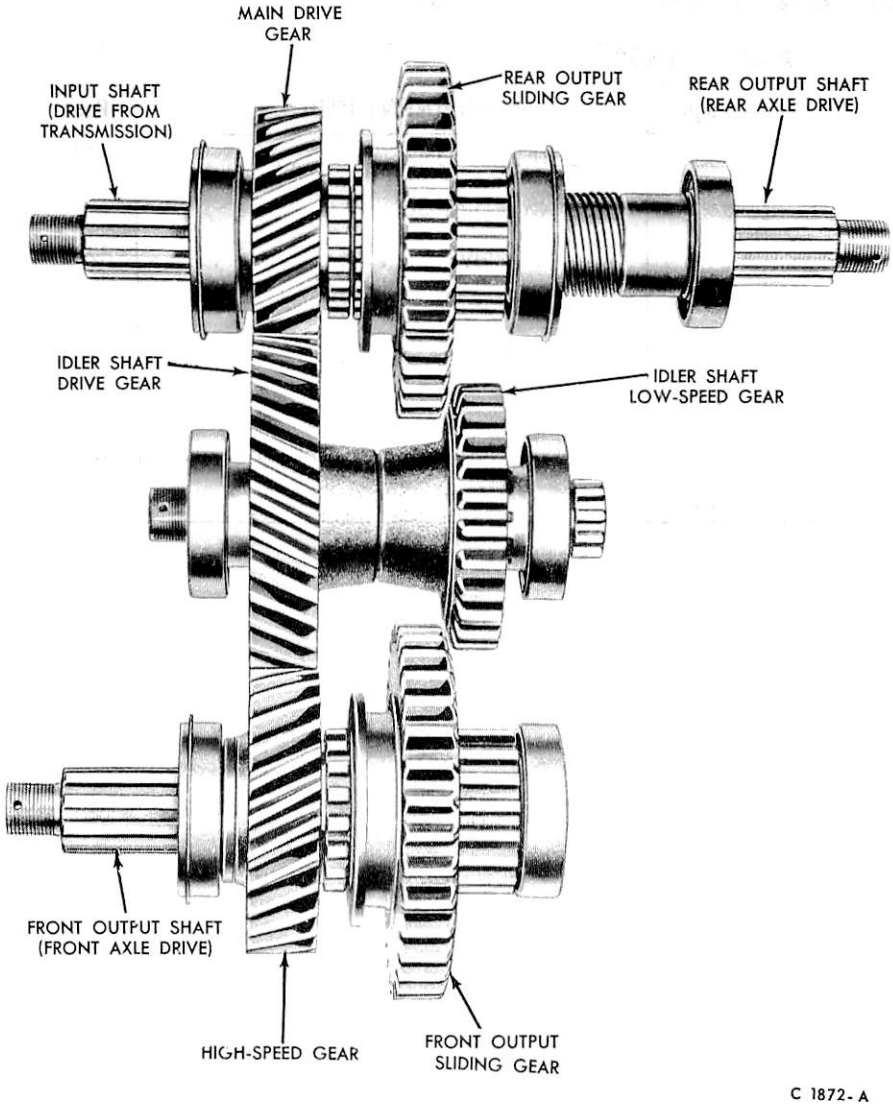

FIG. 1 Transfer Case Gear Train in Neutral

REMOVAL AND INSTALLATION

TRANSFER CASE

Removal

1. Drain the transfer case, and disconnect the rear axle drive shaft from the flange at the transfer case (Fig. 2).
2. Disconnect the front wheel drive shaft and the transmission output shaft at the transfer case.
3. Disconnect the shift selector rod and the speedometer cable at the transfer case.
4. Secure the transfer case to a transmission jack, and remove the mounting bolts.
5. Remove the transfer case, and mount it on a floor stand.

Installation

1. Remove the transfer case from the floor stand and place it on the transmission jack.
2. If necessary to replace a mounting stud, see Fig. 3 for correct positioning of the components.
3. Raise the transfer case into position on the mounting bolts, and install the retaining nuts and lock washers (Fig. 2). Torque the nuts to specification, and remove the jack.
4. Connect the shift selector rod and the speedometer cable.
5. Connect the transmission output shaft. Torque the U-bolt nuts to specification.
6. Connect the front axle drive shaft and torque the universal joint U-bolt nuts to specification.
7. Fill the transfer case to filler plug level with the specified lubricant.

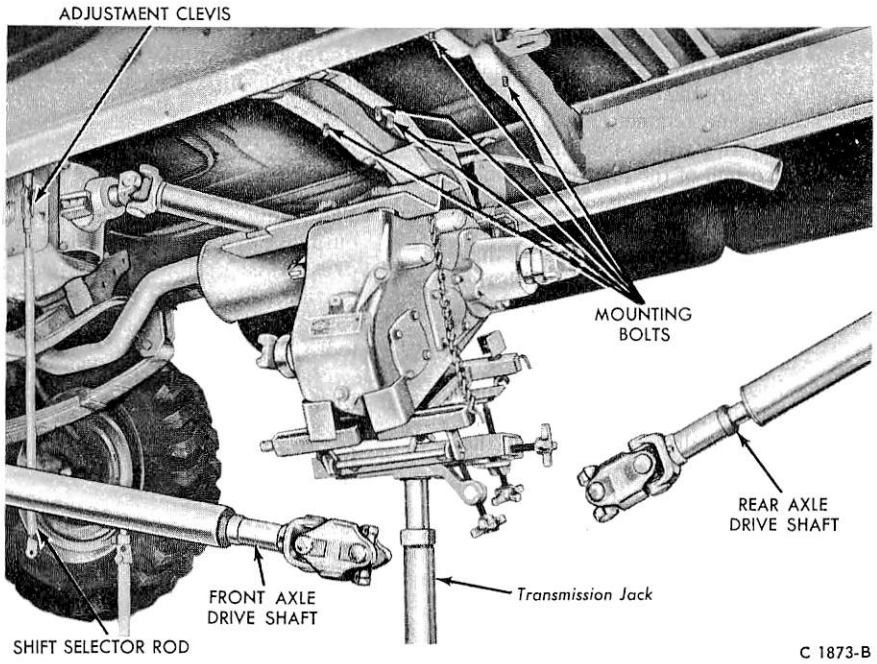

FIG. 2 Removing or Installing Transfer Case

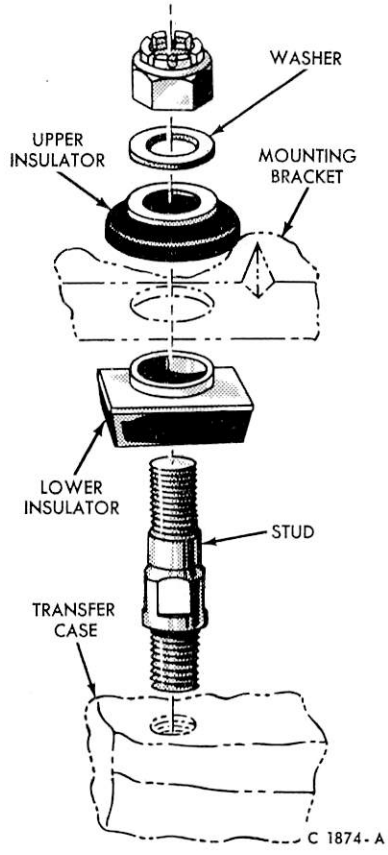

FIG. 3 Transfer Case Mounting Stud

DISASSEMBLY AND ASSEMBLY

TRANSFER CASE

Disassembly

1. Clean the dirt from the transfer case, and remove the power take-off cover plate (Fig. 4).
2. Remove both idler shaft bearing retainers.
3. Using a soft hammer, tap the idler shaft and bearing to the rear until the bearing is free of the case.
4. Remove the idler shaft, two gears and spacer.
5. Remove the idler shaft front bearing from the case.
6. Remove the flange retaining nuts from the front output shaft, the input shaft, and the rear output shaft (Fig. 5).
7. Remove the flanges and washers from the front output shaft, the input shaft, and the rear output shaft (Fig. 6).
8. Remove the front output shaft front and rear bearing retainers.
9. Tap the front output shaft and rear bearing through the gears and case (Fig. 7). Lift the high speed gear from the case.
10. Remove the front output shaft front bearing and washer from the case.
11. Remove the set screw that retains the front drive shaft fork to the shift rail (Fig. 7).
12. Remove the front output shaft sliding gear from the case.
13. If the input shaft oil seal is to be replaced, remove it with a four-jaw puller and slide hammer. Otherwise, leave the oil seal in the front bearing retainer.
14. Remove the input shaft bearing retainer.
15. If the output shaft bearing retainer oil seal is to be replaced, remove it with a puller and slide hammer. Otherwise, leave the oil seal in the bearing retainer.
16. Remove the rear output shaft bearing retainer, and then remove the speedometer drive assembly from the bearing retainer.
17. Loosen the rear output shaft assembly from the case by driving on the front end of the input shaft with a mallet.
18. Remove the rear output shaft and bearing retainer as an assembly (Fig. 8).
19. Tap the input shaft through the front bearing, through the main drive gear, through the sliding gear, and out of the case (Fig. 9).

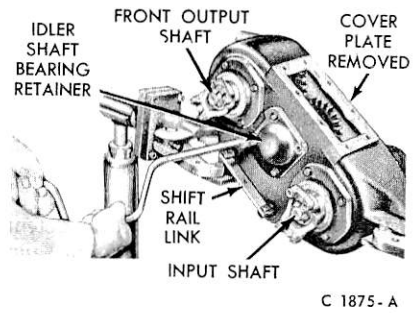

FIG. 4 Front Side of Transfer Case

20. Lift the main drive gear out of the case, and then drive the input shaft front bearing from the case with a mallet.
21. Remove the set screw that retains the rear drive shift fork to the shift rail (Fig. 10).
22. Remove the rear output shaft sliding gear from the case.
23. Remove the shift rail link from the two shift rails (Fig. 4).
24. Remove the retaining plug, detent spring, and ball that engages the front drive shift rail detent rod (Fig. 11).
25. Remove the retaining plug detent spring, and ball that engages the rear drive shift rail detent rod. Then remove the front drive detent rod access hole plug (Fig. 12).
26. Pull the front drive shift rail to the maximum outward position.
27. Pull the rear drive shift rail out far enough to allow the two detent rods to slide out of the case (Fig. 13).
28. Remove the rear drive shift rail and fork from the case.
29. Remove the rear drive shift rail and shift fork from the case.
30. Remove the shift rail seals (Fig. 14).

Assembly

1. Slide the front drive shift rail all the way into the case, and position the shift fork on the rail as the rail goes into the case.
2. Install the two detent rods in the case (Fig. 13).
3. Install the rear drive shift fork, and hold the detent rods and the shift fork in place as the **rear drive** shift rail is pushed in as far as it will go.
4. Pull the **front drive** shift rail out to its next detent. This will permit the **rear drive** shift rail to be pushed in to the full extent of its travel. After pushing the **rear drive** shift rail all the way in, push the **front drive** shift rail back to its extreme inward position.
5. Install the rear drive shift rail detent ball, spring and retaining plug, and then install the access hole plug (Fig. 12).
6. Install the front drive shift rail detent ball, spring and retaining plug (Fig. 11).
7. Secure the shift rail link in the two shift rails.
8. Position the rear output sliding gear in the shift fork, secure the fork to the rear drive shift rail with the set screw (Fig. 10).
9. Install the input shaft front bearing and retainer assembly. Coat the retainer and bolts with sealer.
10. Position the main drive gear in the case. Then slide the input shaft into the rear of the case through the main drive gear, then through the front bearing and retainer (Fig. 9).
11. Install the roller bearing in the splined hub of the rear output shaft assembly with petrolatum or grease. Then install the shaft and bearing retainer assembly, making sure that the output shaft is aligned with the input shaft (Fig. 8). Coat the case, bearing retainer and bolts with sealers.
12. Position the front output sliding gear in the shift fork, secure the fork to the front drive shift rail with the set screw.
13. While holding the sliding gear and high speed gear in position, install the front output shaft and rear bearing assembly through the two gears from the rear of the case (Fig. 7).
14. After coating the retainer and bolts with sealer, install the front output shaft rear bearing retainer and gasket.
15. Install the washer and front bearing over the front output shaft at the front of the case (Fig. 7), and then install the front bearing retainer and gasket. Coat the retainer with sealer.
16. Install the flange, washer, flange retaining nut and cotter key on each of the three shafts, using the tool shown in Fig. 5. Torque the nuts to specification.
17. Position the idler shaft gears in the case and install the idler shaft and rear bearing assembly from the rear of the case. After applying sealer to the plate and bolts, install the rear bearing retainer plate.
18. Position the spacer on the front end of the idler shaft and install the front bearing. Tap the bearing lightly with a mallet.
19. Install the washer, retaining nut and cotter pin on the front end of the idler shaft.
20. After applying sealer to the plate and bolts, install the idler shaft front bearing retainer plate.
21. After applying sealer to the plate and bolts, install the power take-off cover plate.

SUB-ASSEMBLIES

IDLER SHAFT BEARING

To remove or install the idler shaft rear bearing, use the tool shown in Fig. 15.

FRONT OUTPUT SHAFT BEARING

To remove or install the front output shaft rear bearing, use the tool shown in Fig. 15.

REAR OUTPUT SHAFT BEARING

Disassembly

1. Place the bearing retainer and rear output shaft assembly in a press, and press the shaft out of the rear bearing and retainer.
2. Remove the front bearing with the tool shown in Fig. 15.

Assembly

1. Install the front bearing as shown in Fig. 16.
2. Install the rear bearing and retainer (Fig. 17).

OIL SEALS

To install a new oil seal in any of the bearing retainers, press the seal into the retainer with the tool shown in Fig. 18.

1. Install the two shift rail oil seals in the case, using the tool shown in Fig. 19.

In steps 2 and 3, the shift rails should be inserted so that the detents are positioned as shown in Fig. 20.

DESCRIPTION

TRANSFER CASE

The Rockwell 223-C9 transfer case (Figs. 1, 3 and 4) is a two-speed unit used to transmit power to both the front and rear driving axles on the Ford F-600 4 x 4 truck.

An internal-expanding parking brake is mounted on this transfer case.

A two-lever control system for the unit is mounted in the truck cab.

ADJUSTMENTS

TRANSFER CASE

Instructions for adjusting the shift and parking brake linkage are given in Figure 2.

REMOVAL AND INSTALLATION

TRANSFER CASE

Removal

1. Drain the transfer case.
2. Disconnect speedometer cable.
3. Disconnect the output and input shafts and use wire or rope to secure shafts out of the way. **Do not let the shafts hang.**
4. Disconnect parking brake rod at the parking brake bellcrank. Secure rod out of the way.
5. Remove clevis pins and washers and disconnect de-clutch and shift control rods from the shift rails. Secure rods out of the way.
6. Using a transmission jack, support the transfer case while removing the case to support bracket bolts (Fig. 1).
7. Carefully lower case to the floor and remove from under truck.

Installation

1. Using a transmission jack, raise the transfer case and align the threaded mounting holes with the holes in the mounting brackets.
2. Install and torque the mounting bolts.
3. Connect the parking brake rod at the parking brake bellcrank (Fig. 2). Adjust if necessary (Fig. 2).
4. Connect the de-clutch and shift control rods and install clevis pins, washers and cotter pins. Adjust if necessary (Fig. 2).
5. Connect the output and input shafts.
6. Connect the speedometer cable.
7. Fill the transfer case with the specified lubricant.

DISASSEMBLY AND ASSEMBLY

TRANSFER CASE

Disassembly

1. Clean the exterior of the case before proceeding with disassembly.
2. Remove the three driving yokes from the input and output shafts, using a standard slide-hammer as required.
3. Remove the attaching capscrews and washers and lift off the cover and gasket (Fig. 5).

Shift Components

1. Remove the detent springs and use a magnet to remove the detent balls (Fig. 5).
2. Pull both shift shafts out through the front of the case (Fig. 6). If the shafts cannot be removed in this manner, use a soft metal drift and drive the shafts and expansion plugs out through the rear of the case (Fig. 6).
3. Remove the shift shaft oil seals from the front of case if worn or if they are to be replaced.
4. Lift out the range shift and the de-clutch forks.

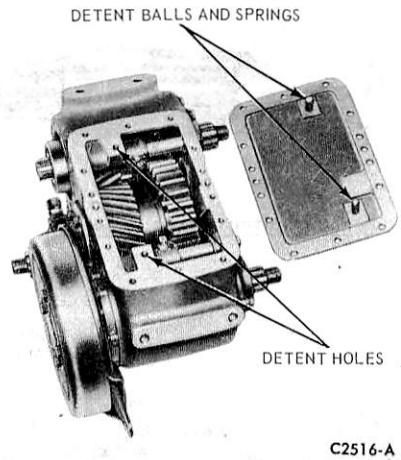

FIG. 5 Removing Cover

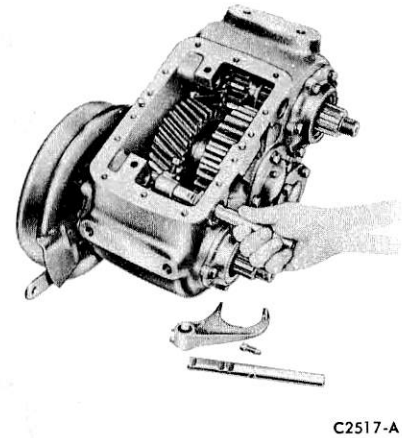

FIG. 6 Removing Shift Shafts

Front Output Shaft

1. Remove the front output shaft bearing cap and gasket (Fig. 7). Pull the shaft and de-clutch collar from the case.
2. Slide a long bar through the front output shaft gear and tap out the small and large expansion plugs located in the brake hub (Fig. 8).

Parking Brake

1. Cut the lock wire and remove the capscrews retaining the brake drum to the brake flange. Remove the drum.
2. Remove the brake hub retaining snap ring (Fig. 9).

3. Using a suitable puller, remove the brake hub from the front output shaft gear (Fig. 10).
4. Unhook the brake shoe return springs and remove the brake shoes and lever (Fig. 11).
5. Remove the mounting bolts and lift off the brake backing plate, washer, deflector and gasket (Fig. 12). **Do not attempt to remove the front output gear at this time. The idler shaft must be removed first, as the gears interfere, otherwise.**

Idler Shaft

1. Remove the idler shaft front and rear bearing caps. Wire the forward bearing cap shims together for re-assembly.
2. Remove the screws and retainer plate from the front end of the idler shaft and then press the shaft out through the rear of the case (Fig. 13).
3. Lift out the low gear, spacer and front bearing (Fig. 14).
4. Remove the high gear. Tap the idler shaft front bearing cup from the case.
5. Remove the snap ring (Fig. 15) and press the bearing from the idler shaft.

Front Output Gear

1. With the idler shaft assembly removed, the front output gear and bearing can now be removed. Remove the front output gear rear bearing cap and gasket.
2. Remove the bearing-retaining snap ring and tap the gear and bearing into the case. Reach through the cover opening and lift out the gear and bearing (Fig. 16).
3. Press the bearing off the shaft.

Rear Output Shaft

1. To remove the rear output shaft, remove the capscrews and lift off the front and rear bearing caps. Wire the shims together for re-assembly.
2. Remove the speedometer drive gear and spacer.
3. Block the rear output gear with a piece of wood as shown in Fig. 17 and press the rear output shaft and front bearing out of the case. The rear output gear and rear bearing can be lifted out of the case through the cover opening.

Input Shaft

1. Remove the input shaft front and rear bearing covers. Wire the shim pack together for re-assembly.
2. Using a block of wood between the sliding gear and the case (Fig. 18), press out the input shaft and front bearing. **Do not pound on the shaft if the gear becomes bound.**
3. Lift out the sliding gear, drive gear and spacer (Fig. 19).
4. Remove front bearing from the input shaft.

ASSEMBLY

Input Shaft

1. Install the input shaft front bearing on the input shaft with the shielded side against the shaft shoulder (Fig. 4).
2. Start the input shaft into the case. Working thru the cover opening, mount the sliding gear, spacer and drive gear (with bushing) on the input shaft.
3. Using a suitable sleeve against the inner race of the front bearing, (Fig. 20) tap the input shaft into position.
4. Position the original shim pack plus an additional 0.010 inch of shims to make sure there is end play in the assembly. Install the front cover and tighten the capscrews to the specified torque (see Specifications of this Part).
5. Place the thrust washer on the shaft and install the rear bearing with the shielded side toward the inside.
6. Position a new gasket and install the bearing cover to the rear of the case. Tighten the capscrews to specifications.
7. Mount a dial indicator with the stem against the front end of the input shaft (Fig. 21) and check the amount of end play in the shaft assembly. **Remove enough shims from under the front bearing cap to arrive at 0.003-0.005 inch end play.** Tighten the retaining capscrews to specifications.

Rear Output Shaft

1. Using a suitable sleeve, press the front bearing onto the rear output shaft (Fig. 22).
2. Hold the rear output gear in position inside the case (Fig. 22) and slide the shaft through it.
3. Install the front bearing cup and the original shim pack plus an additional 0.010 inch of shims. Install the front bearing cover, lock washers and capscrews and torque the cap screws to specifications.
4. Using a suitable sleeve, press the rear bearing onto the rear output shaft (Fig. 23). Tap the bearing cup into position.
5. Install the speedometer drive gear and spacer over the shaft.
6. Position a new gasket, bearing cap and oil seal over the shaft. Install the lock washer and capscrews and torque the capscrews to specifications.
7. Rotate the shaft to seat the bearings. Mount a dial indicator against the rear end of the shaft to check the amount of end play in the assembly (Fig. 24).
8. **Remove sufficient shims from under the front bearing cap to arrive at an adjustment of zero end play and zero preload.**

Front Output Gear

1. **The front output gear must be installed in the case before the idler assembly is installed.**
2. Install the ball bearing on the front output gear hub (Fig. 4).
3. Position the gear and bearing in the case and install the retaining snap ring on the bearing (Fig. 25).
4. Install the rear bearing cap over a new gasket. Install the capscrews and lock washers and torque the capscrews to specifications.

Idler Gear

1. Press the rear bearing on the idler shaft (Fig. 4) and install the snap ring.
2. Hold the high gear in position inside the case and tap the idler shaft through it with a soft hammer (Fig. 26). The short hub side of the gear faces toward the vehicle rear.
3. Install the gear spacer on the idler shaft and then install the low gear with the long hub toward the vehicle front of the case.
4. With the shaft in position, install the rear bearing cup in the case. Use a new gasket and install the rear bearing cap, lock washers and cap screws. Torque the capscrews to specifications.
5. Drive the front bearing onto the idler shaft (Fig. 27). Hold the shaft rigid to avoid damaging the rear bearing and cup. Install the bearing retainer plate and capscrews. Lock wire the capscrews.
6. Tap the front bearing cup into place in the case.
7. Install sufficient extra shims to set up end play in the idler assembly. Install the front bearing cap and secure with lock washers and capscrews. Torque the capscrews to specifications.
8. Mount a dial indicator on the case with the stem set against the inside face of the low gear (Fig. 28). Check the amount of end play by working the assembly back and forth with two prybars as shown in Figure 28. **Remove sufficient shims to get a bearing end play adjustment of 0.003-0.005 inch.**

Front Output Shaft

1. Begin the installation of the front output shaft by installing the ball bearing on the shaft with the bearing snap ring toward the outside (Fig. 4).
2. Install the sliding collar on the shaft. Slide the shaft into the case (Fig. 29).

3. With the shaft in position, install a new gasket, bearing cap and oil seal. Secure in position with lock washers and capscrews. Torque the capscrews to specifications.

Parking Brake

1. Position a new gasket to the case and then mount the brake backing plate, deflector and stamped washer. Insert the capscrews with star washers and tighten to specifications.
2. Position the brake lever on the backing plate.
3. Position the brake shoes on the backing plate with actuating pawl in the web slot.
4. Install brake shoe return springs.
5. Slide the brake hub over the splines of the front output gear. Install the retaining ring.
6. Install the brake drum with lock washers and capscrews. Torque the capscrews to specifications and insert lock wire.
7. Install the expansion plugs. The smaller plug goes in the bore of the front output gear and the larger in the brake hub.

Shift Components

1. Install new shift shaft oil seals in the case, if required.
2. Position the de-clutch fork in the collar.
3. Lubricate the de-clutch shift shaft and slide it into the case and through the shift fork bore.
4. With the shift shaft in position, insert the set screw. Tighten the screw and lock wire to the fork.
5. Position the range shift fork in the sliding gear.
6. Slide the range shift shaft through the bore of the fork. Install the set screw and tighten lock wire to the shift fork.
7. Install the expansion plugs at the rear of the case and flatten to expand.
8. Place the detent balls and springs in position in the case bores.
9. Install the cover with a new gasket and tighten the retaining capscrews to the specified torque.
10. Install the input shaft rear bearing cover, using a new gasket. Tighten the retaining capscrews to specifications.
11. Install the driving yokes and torque the retaining nuts to specifications.

Description

Transfer Case

This manually-shifted unit provides two speed operation by means of a constant-mesh helical gear train. Speeds are changed by using sliding clutch gears. A single shift lever controls the integrated shift linkage system.

Adjustment

Instructions and specifications for linkage adjustment are given in Figures 2, 3 and 4.

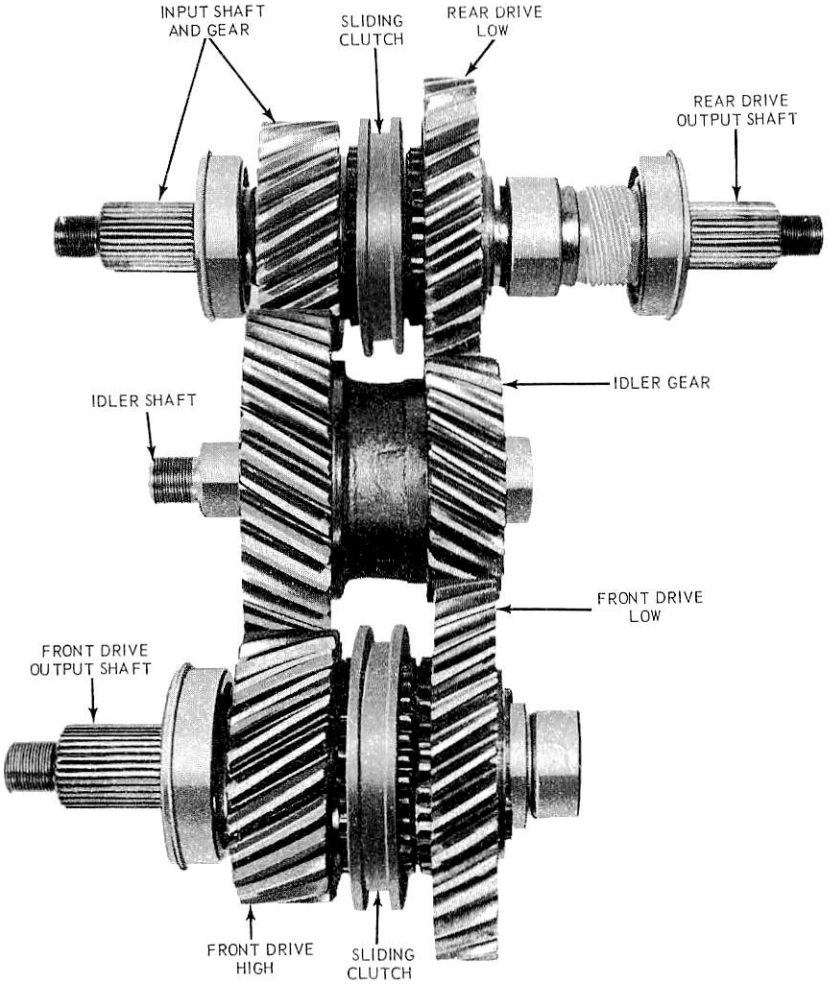

FIG. 1 Gear Train-Model 205 Transfer Case

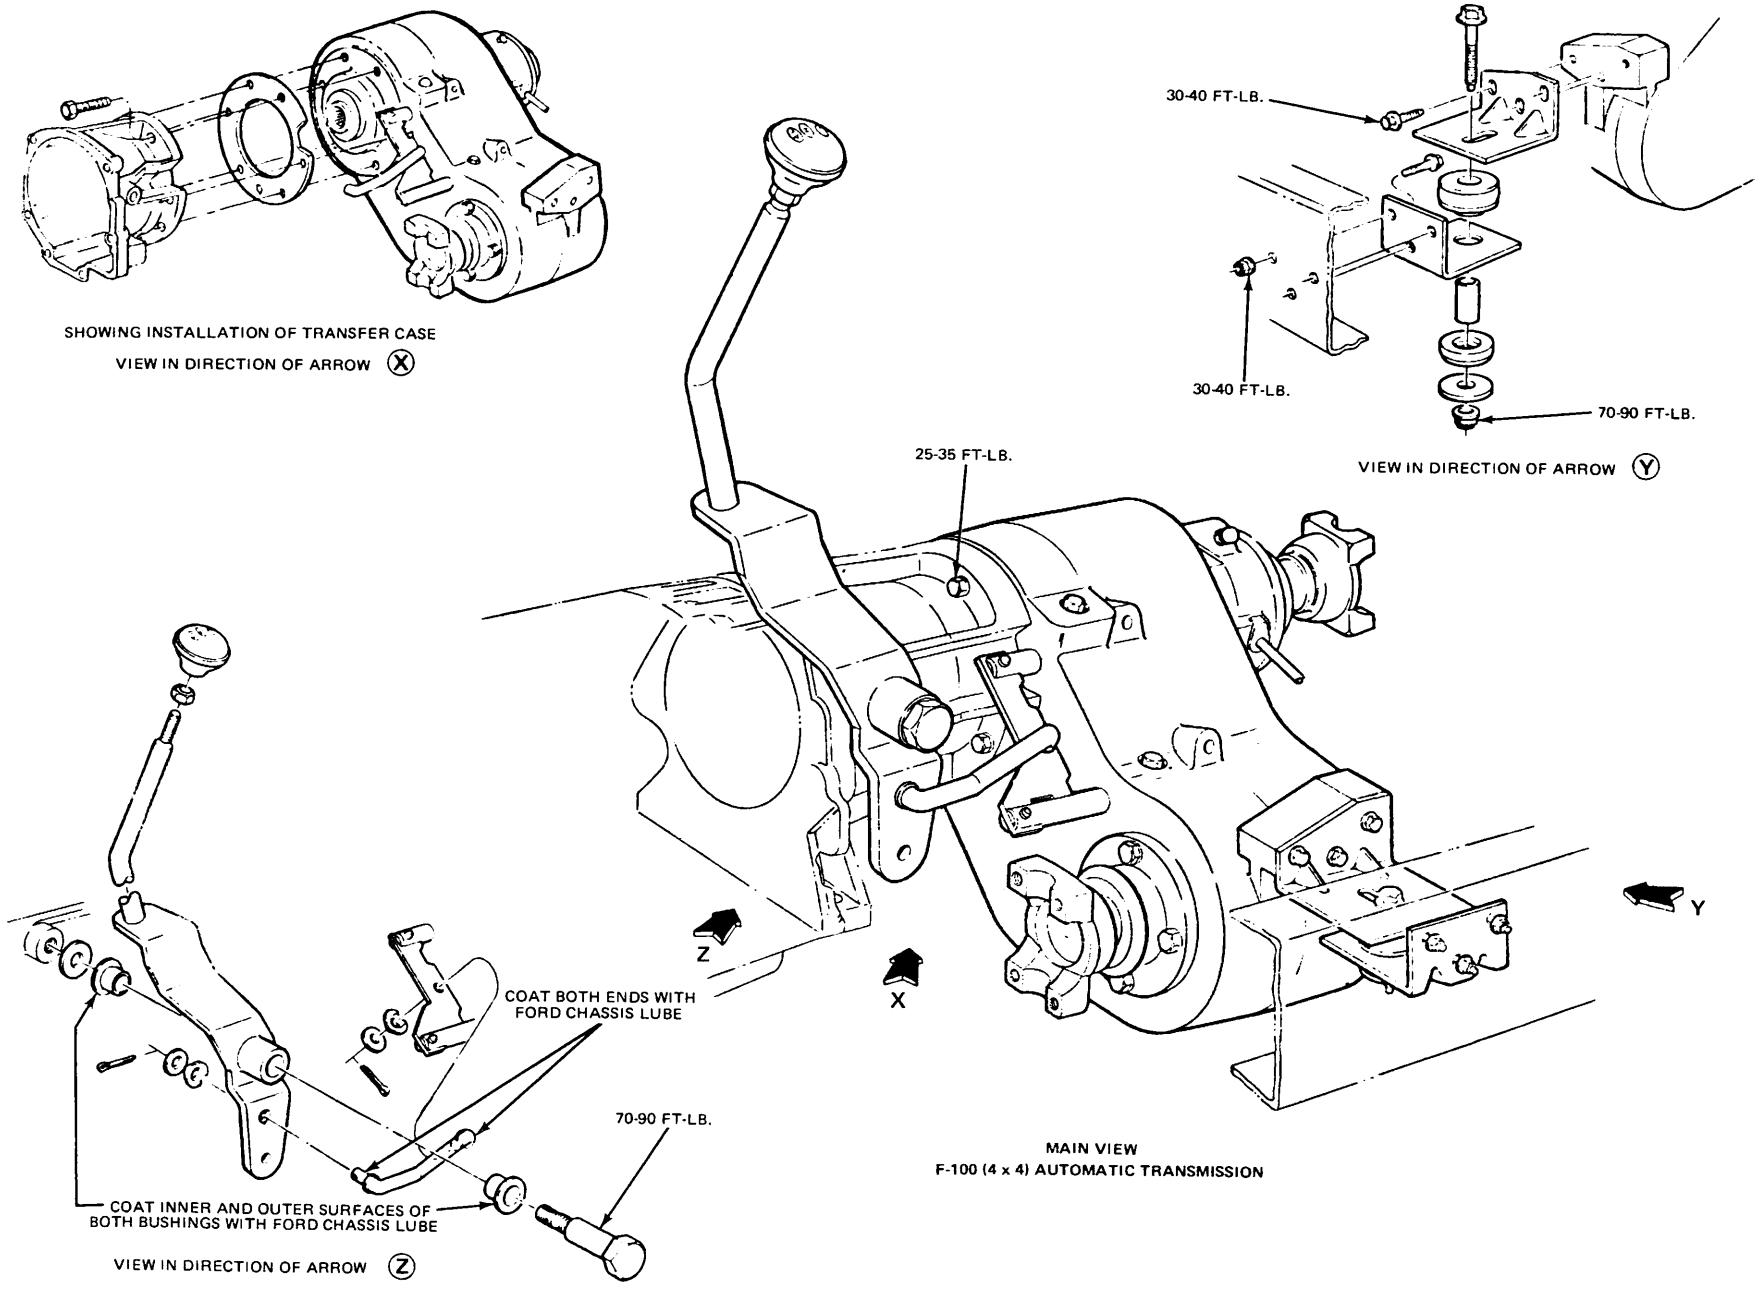

FIG. 2 Model 205 Transfer Case Installation—F-100

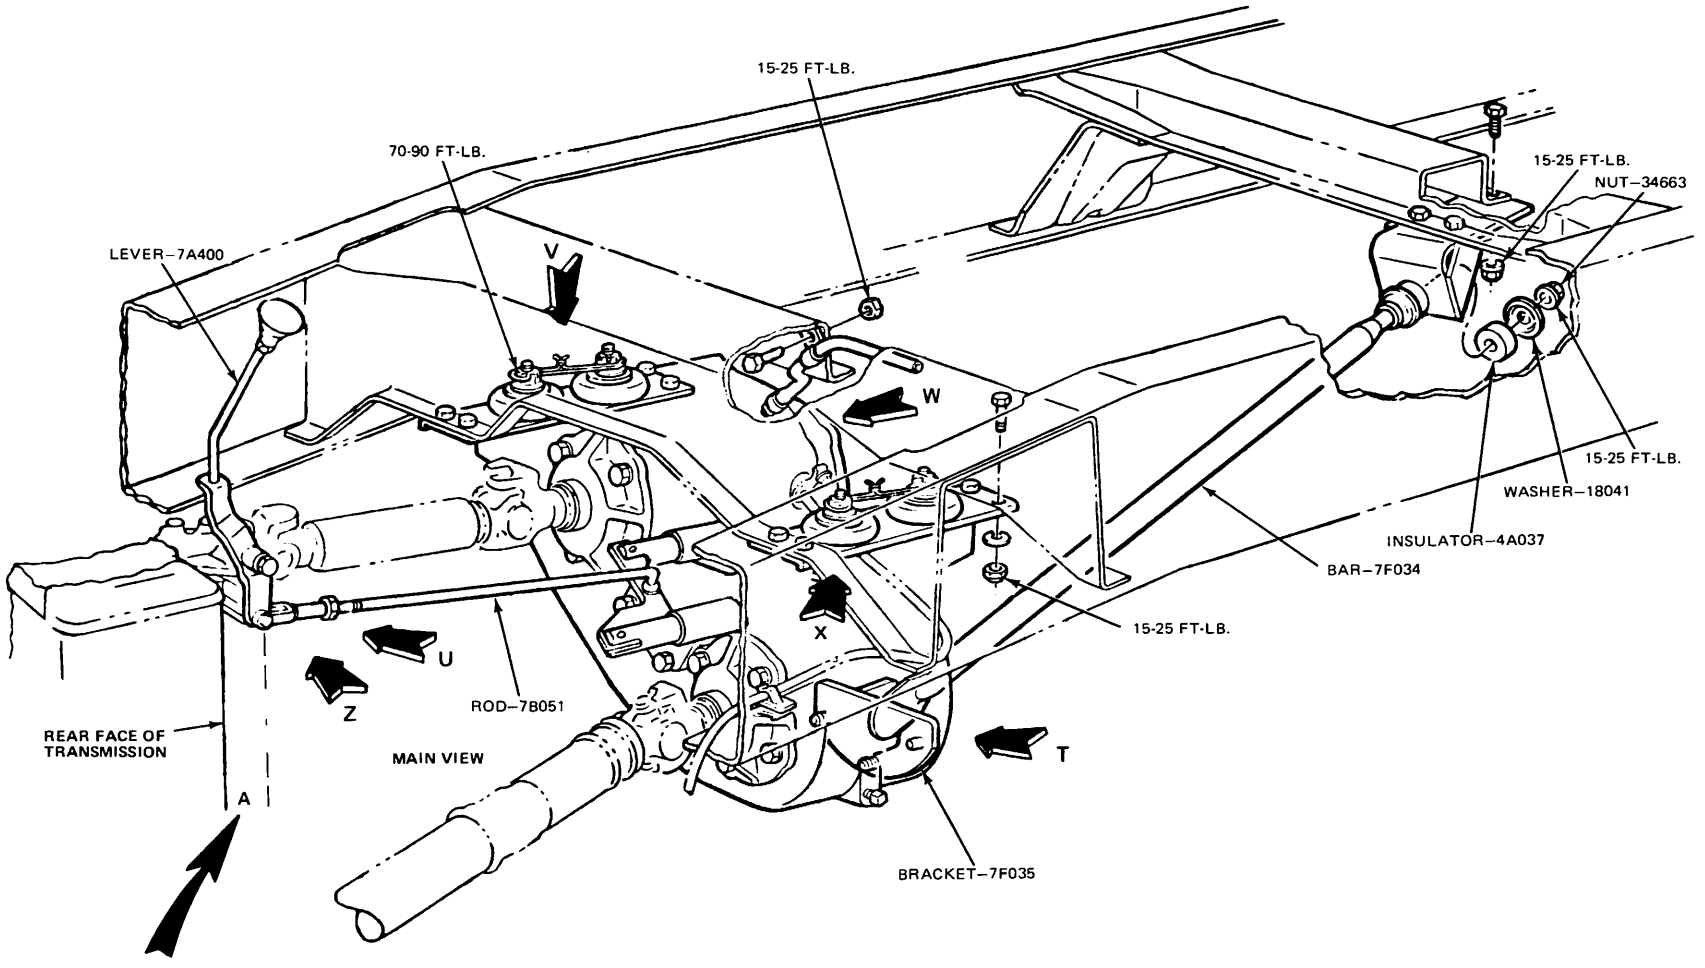

ADJUSTMENT: MODEL 435 MANUAL TRANSMISSION

TRANSFER CASE MUST BE IN 4 WHEEL LOW (CROSS LINK ASSEMBLY ALL THE WAY IN)

DIMENSION "A" MUST BE $\frac{3.94}{3.82}$

ADJUST ROD (7B051) TO CORRECT LENGTH AND TIGHTEN LOCK NUT AT CLEVIS. SEE FIGURE C2711-A FOR AUTOMATIC TRANSMISSION | LINKAGE ADJUSTMENT

DETAILS OF VIEWS T–U–V–W–X–Y–Z ARE SHOWN ON FIGURE C2711-A

C2710-A

FIG. 3 Model 205 Transfer Case Installation—F-250

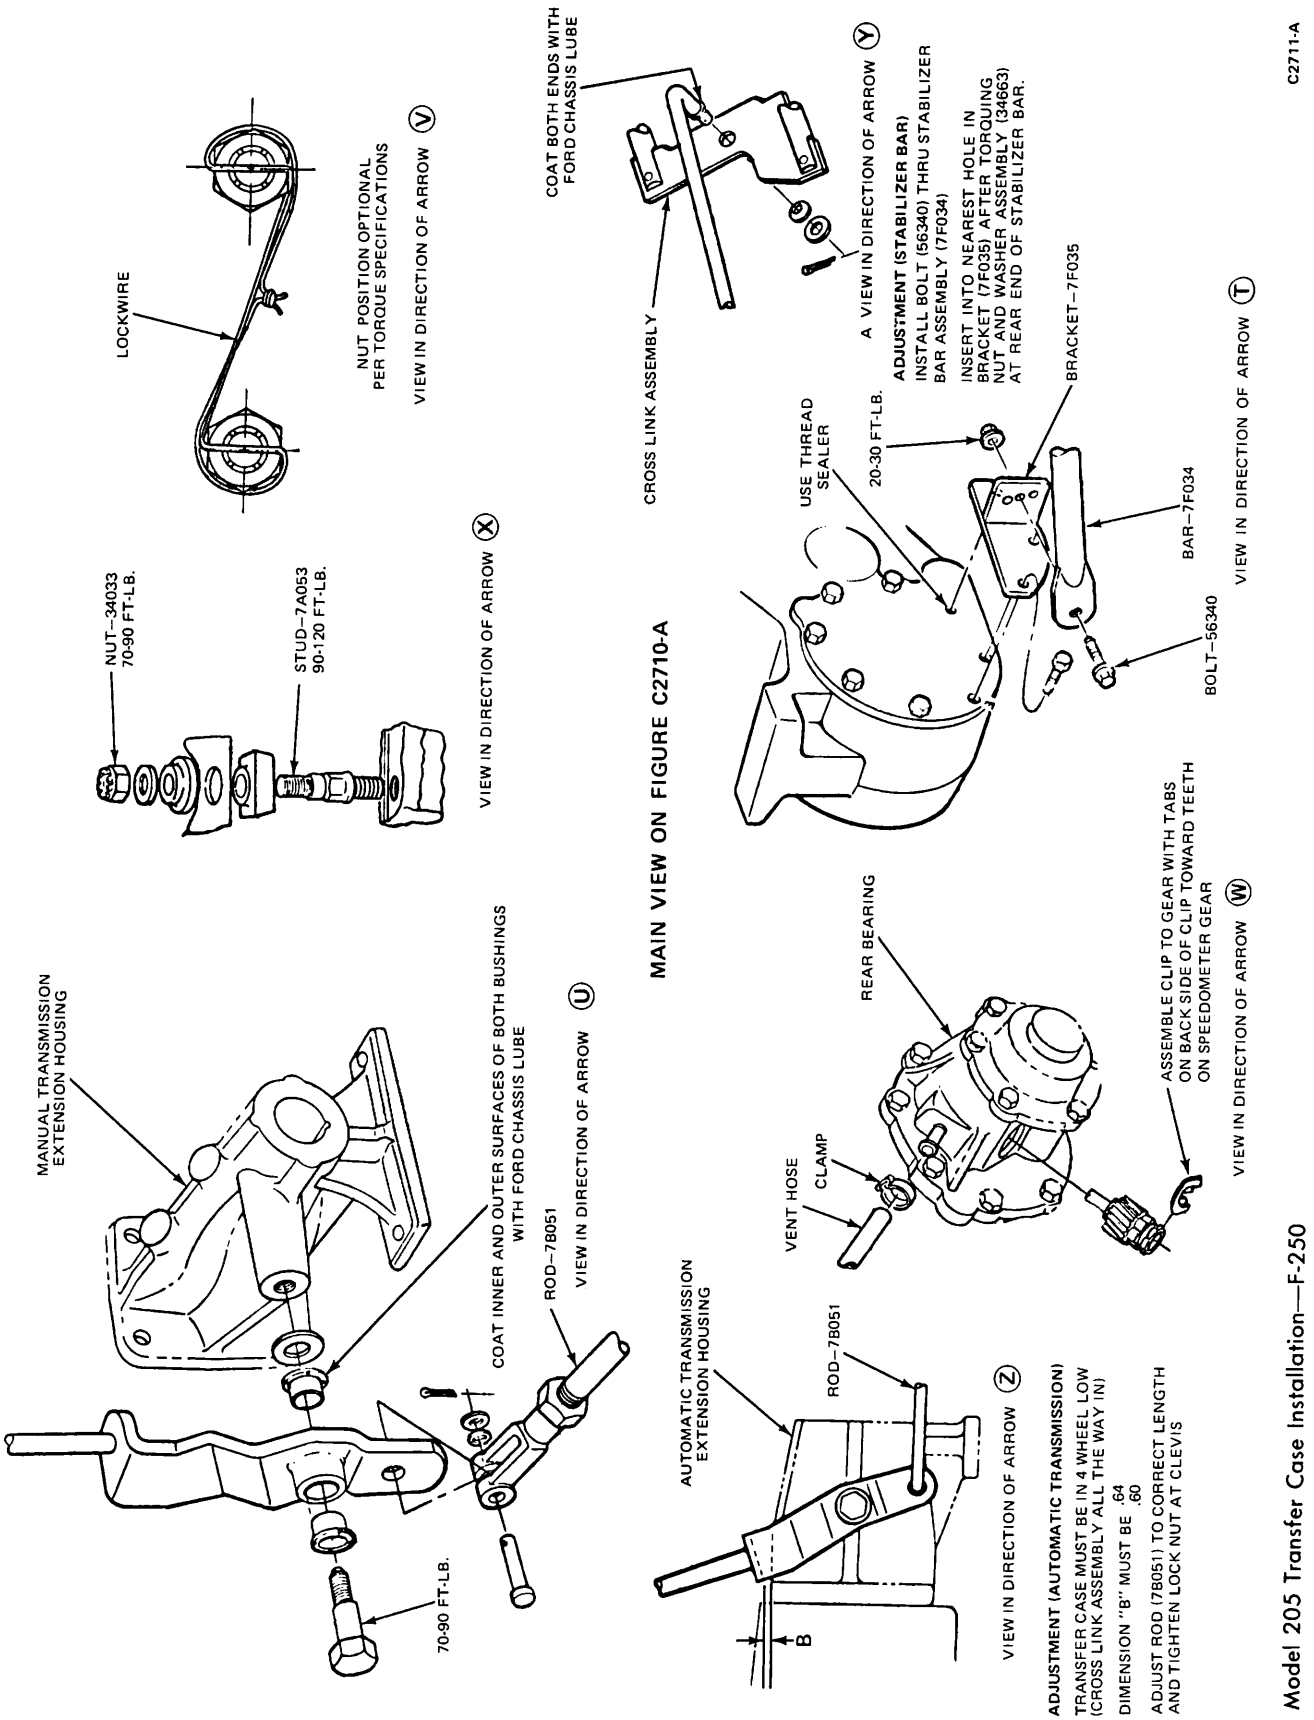

FIG. 4 Model 205 Transfer Case Installation—F-250

REMOVAL AND INSTALLATION

Transfer Case

Removal

1. Drain the transfer case, and disconnect the rear axle drive shaft from the flange at the transfer case (Fig. 2).
2. Disconnect the front wheel drive shaft and the transmission output shaft at the transfer case if on F-250 installation (Fig. 3 and 4). On F-100 installations, disconnect the front wheel drive shaft and remove the bolts attaching the transmission adapter to the transfer case (Fig. 2).
3. Disconnect the shift selector rod and the speedometer cable at the transfer case.
4. Secure the transfer case to a transmission jack, and remove the mounting bolts.
5. Remove the transfer case, and mount it on a floor stand or place on a work bench.

Installation

1. Remove the transfer case from the floor stand or bench and place it on the transmission jack.
2. If necessary to replace a mounting stud on an F-250, see Fig. 3, for correct positioning of the components.
3. Raise the transfer case into position on the mounting bolts. If an F-100 installation, mate the transfer case to the transmission adapter and install and torque the attaching bolts (Fig. 2). Install the mount attaching bolts, nuts and lock washers (Figs. 2, 3 and 4). Torque the bolts and nuts to specification, and remove the jack.
4. Connect the shift selector rod and the speedometer cable.
5. If an F-250 installation, connect the transmission output shaft to the transfer case input shaft. Torque the U-bolt nuts to specification.
6. Connect the front and rear axle drive shafts and torque the universal joint U-bolt nuts to specification.
7. Fill the transfer case to filler plug level with specified lubricant.

DISASSEMBLY AND ASSEMBLY

Transfer Case

Disassembly

1. Clean the exterior of the case.
2. Using a flange-holding tool, loosen the lock nuts and universal joint flanges.
3. Remove the front output shaft rear bearing retainer, (large aluminum plate) front bearing retainer and drive flange (Figs. 5 and 6).
4. Using a soft-faced hammer, tap the shaft assembly from the case (Fig. 7). Remove the sliding clutch, front output high gear, washer and bearing which remain in the case.
5. Remove rear output shaft housing attaching bolts and remove the housing and bearing retainer along with the speedometer gear (Fig. 8).
6. Slide the rear output shaft from the case (do not lose 15 needle bearings).
7. Using a blunt punch, drive the two 1/4 inch shift rail pin access hole plugs into the case.
8. Remove the two shift rail poppet (detent) nuts and springs from the case. Using a magnet, remove the two poppet balls.
9. Position both shift rails in neutral and remove the shift fork retaining roll pins, using a longhandled screw extractor or punch.
10. Remove one shift rail to shift rail link clevis pin.
11. Remove the range shift rail first, then the 4 wheel shift rail (Fig. 9).
12. Remove shift forks and sliding clutch from case.
13. Remove the cup plugs and rail pins (if driven out) from the case.
14. Remove idler gear shaft lock nut.
15. Remove idler gear shaft rear cover.
16. Remove idler gear shaft using Tool J-23429 and a soft-faced hammer.
17. Roll idler gear assembly to front output shaft hole and remove from case (Fig. 10).

Assembly

1. Assemble idler shaft, bearings, spacer and shims to the dummy shaft Tool J-23429. Install the assembly into the case through the front output shaft bore, large end first.
2. Install idler shaft from large bore side and drive into position, using a soft-faced hammer (Fig. 11).
3. Install washer and new lock nut. Check for free idler gear rotation. Torque the lock nut to specifications
4. Position the idler shaft cover so that the flat faces the front output shaft rear bearing retainer (cover). Install a new gasket and the retaining capscrews and torque to specifications.
5. If removed, install interlock pins into the inter-lock bore, working through the front output shaft opening.
6. Start 4 wheel drive shift rail into the case from the front, solid end first, with detent notches up.
7. Position shift fork onto the shift rail with the long end facing inward. Push the rail through the fork and into neutral position.
8. Position input shaft and bearing into case (Fig. 13).
9. Start engine shift rail into case from front, with detent notches up.
10. Position sliding clutch to fork. Position the sliding clutch on the input shaft and align fork with shift rail. Push rail through fork into neutral position.
11. Using a long punch, install the roll pins locking the shift forks to the shift rails.
12. Position front wheel high gear and thrust washer in case. (Fig. 14). Position the sliding clutch in the shift fork. Shift rail and fork into the front wheel drive (4 -Hi) position while meshing the internal teeth of the sliding clutch with the mating teeth on the front wheel high gear.

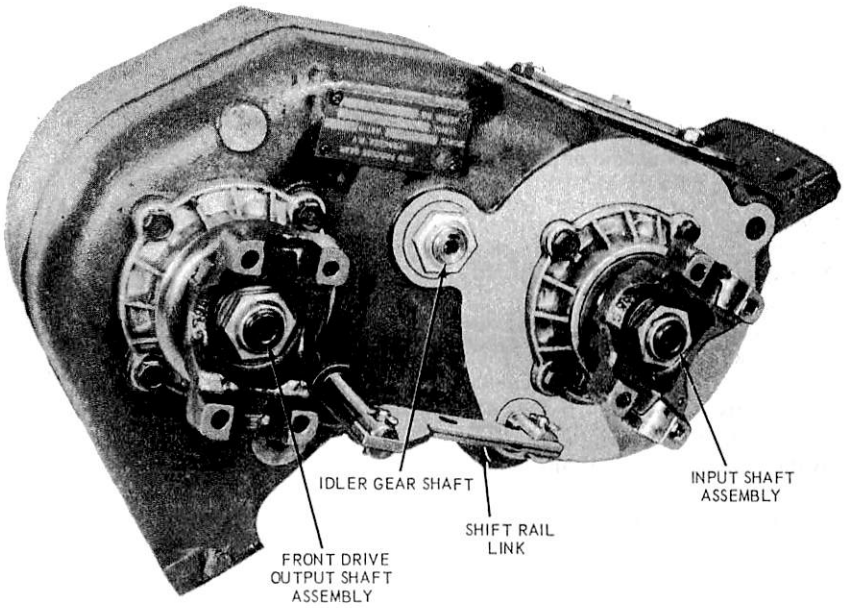

FIG. 5 Model 205 Transfer Case-Front View

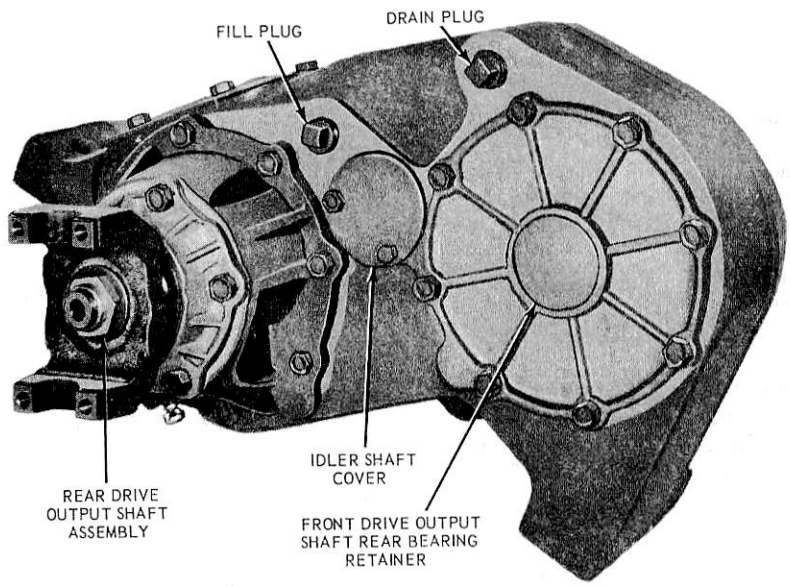

FIG. 6 Model 205 Transfer Case-Rear View

13. Line up thrust washer, high gear and sliding clutch with bearing bore in case and insert front output shaft and low gear into the high gear assembly (Fig. 14).
14. Install a new seal in front output shaft front bearing retainer (Fig. 12) and install bearing and retainer and new gasket in case. Torque the cap screws to specifications.
15. Lubricate the roller bearing in the front output shaft rear bearing retainer (aluminum cover) and position to shaft and case, using two new gaskets. Apply thread sealer to the attaching cap screws, install and torque to specifications.
16. Position range shift rail in High and install rear output shaft and retainer assembly to housing and input shaft, (Fig. 8), using one or two new gaskets as required for clearance on the input shaft pilot.
17. Install and torque rear output shaft housing bolts to specifications.
18. Install shift rail pin access plugs using a punch and sealing compound.

19. Install drain and fill plugs and torque to specifications.
20. Install cross-link clevis pin.

Sub-Assemblies

REAR OUTPUT SHAFT

Disassembly (Fig. 13)

1. Remove snap ring from the rear output shaft and slide off the thrust washer. Remove the washer-positioning pin.
2. Remove tanged thrust washer from shaft and slide off the low speed gear, making provision to catch the two rows of needle bearings (32 per row) and spacer.
3. Remove remaining tanged thrust washer.
4. Using a hooked tool, remove the retainer ring, washer, needle bearings and spacer from the pilot bore of the rear outut shaft.
5. Remove rear bearing retainer and ball bearing from the rear output shaft bearing housing.
6. Remove the caged roller bearing from the housing only if replacing.

Assembly (Fig. 13)

1. Install new bearing retainer oil seal into the bearing retainer.
2. Install a new caged roller bearing into the bearing housing, if required.
3. Install the roller bearings, spacer, washer and retainer ring in the pilot bore of the rear output shaft, using low melting point petrolatum.
4. Install tanged thrustwasher onto output shaft with the tang indexing in the groove in the clutch teeth.
5. Position the output shaft low gear on the output shaft and using the shaft and petrolatum as assembly aids, insert the two rows of roller bearings and the spacer into the gear.
6. Install the second tanged thrust washer on the output shaft with the tang facing away from the gear.
7. Install washer positioning pin and thick thrust washer on the shaft. Rotate the thick washer until the tang on the thin washer (step 6) fits into slot about 90° away from the positioning pin.

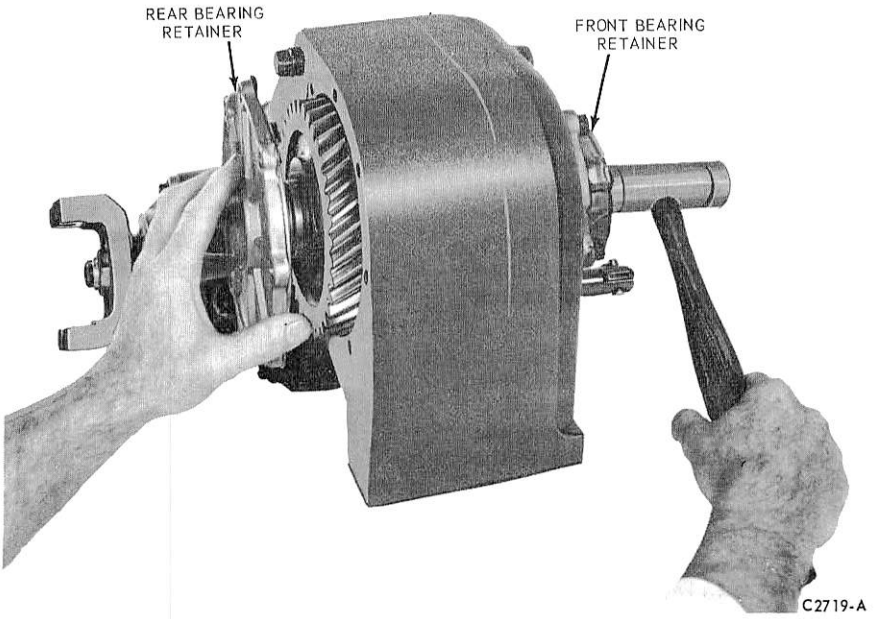

FIG. 7 Removing Front Output Shaft

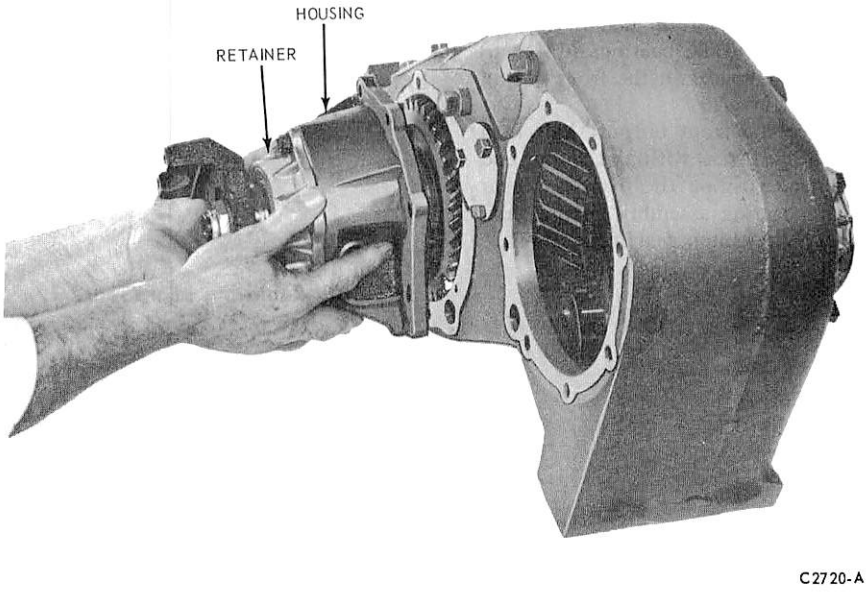

FIG. 8 Removing or Installing Rear Output Shaft

8. Install retaining snap ring.
9. Check end play between the snap ring and the thick thrust washer. It should be 0.002 -0.027 inch.
10. Position the rear output shaft assembly in the output shaft bearing housing and install the speedometer gear and rear ball bearing.
11. Install the rear bearing retainer with new gasket and torque the attaching cap screws to specifications.
12. Install the output drive flange, washer and a new lock nut. Using a flange holding tool, torque the lock nut to specifications.

FRONT OUTPUT SHAFT (FIG. 14)

Disassembly

1. Remove the snap ring retaining the thrust washer and low gear to the shaft.
2. Remove the thick thrust washer and positioning pin.
3. Make provision to catch the roller bearings (two rows of 32 each) and slide the gear off the shaft along with the roller bearing spacer.
4. If necessary to replace the roller bearing in the rear bearing retainer, (aluminum cover) replace the entire assembly.

Assembly

1. Using petrolatum, install the two rows of needle bearings (32 each) and the spacer in the front output shaft low gear.
2. Place the front output shaft in a softfaced vise with the spline end down. Position the front low gear and bearing assembly on the shaft with the clutch gear facing down.

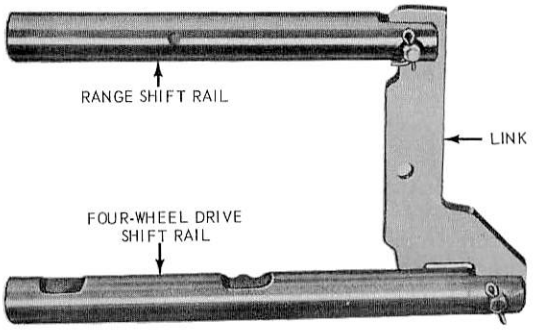

FIG. 9 Shift Rails

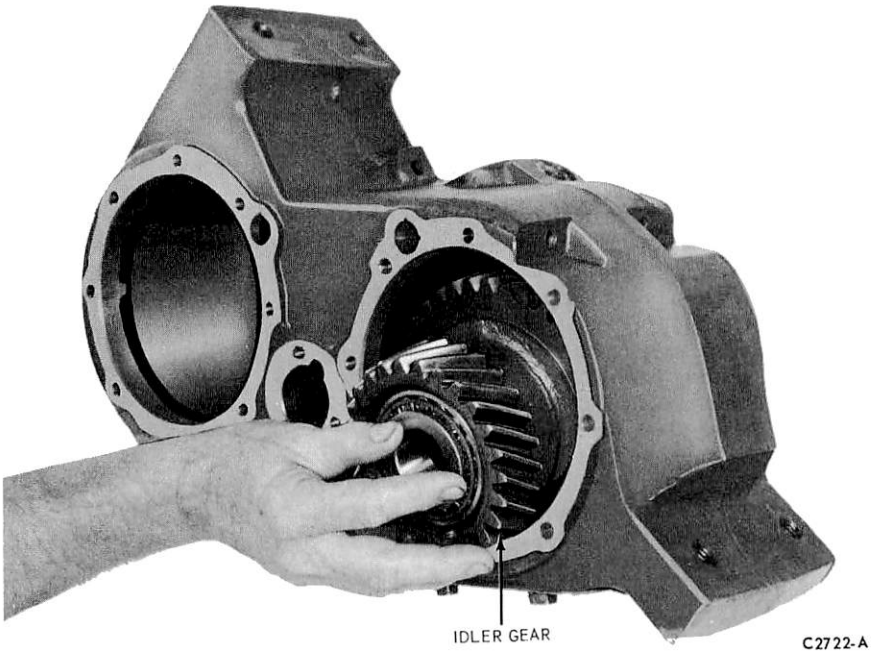

FIG. 10 Removing Idler Gear

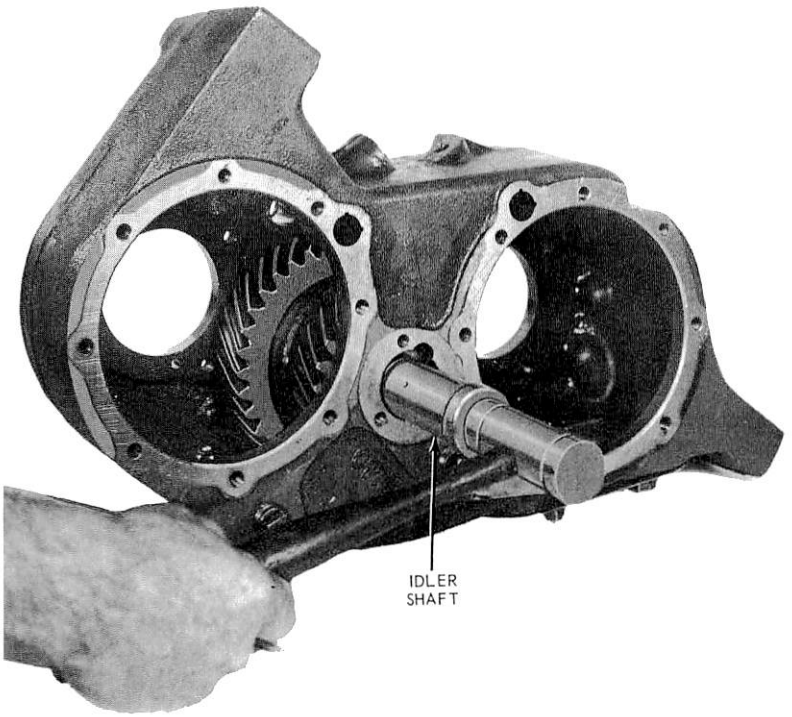
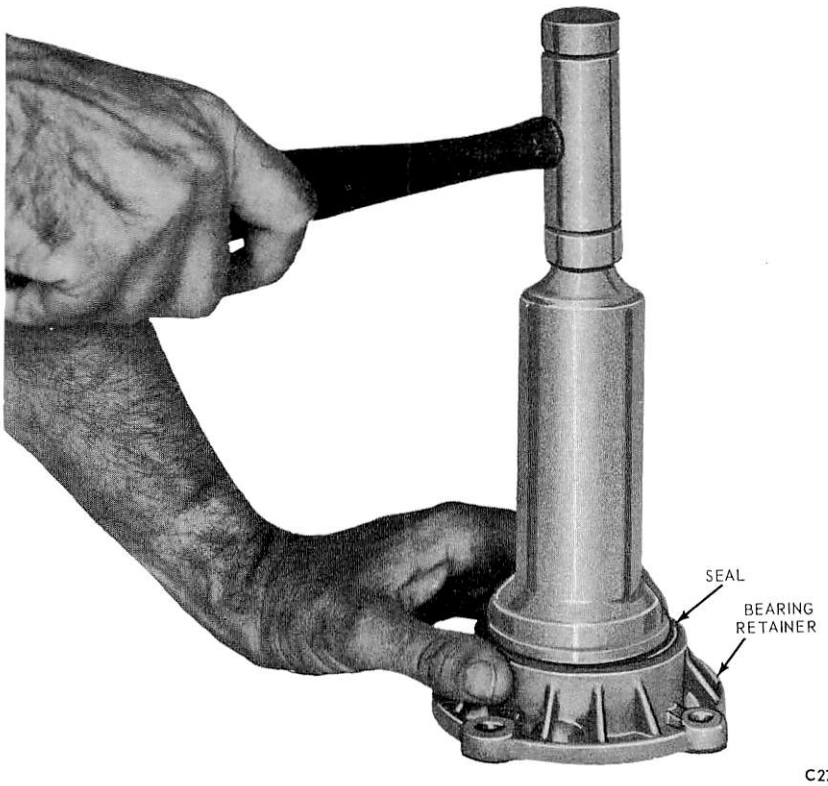


C2724-A

FIG. 11 Installing Idler Gear



C2725-A

FIG. 12 Installing Seal

bearing assembly on the shaft with thee clutch gear facing down.

3. Install thrust washer positioning pin, thrust washer and a new snap ring. Position the snap ring so that the opening is opposite the pin.

IDLER GEAR

Disassembly (Fig. 15)

1. If necessary to replace bearings, drive out the bearing cups using the drive slot provided in the gear bore.

Assembly

Checking End Play-Press Method

1. Press in new bearing cups if removed.
2. Assemble the idler gear, bearings, spacer and shims using the dummy shaft, Tool No. J-23429 or equivalent.
3. Place the assembly in a press and using a piece of pipe that will clear the dummy shaft, apply enough pressure to the bearing cones to remove looseness between the bearing spacer and shims (Fig. 16.) Using a dial indicator check the end play between the bearing cones and cups. Tolerance should be 0 to 0.002 inch. Adjust this tolerance by adding or subtracting shims between the bearings and the bearing spacer.

Checking End Play (Vise Method)

1. Assemble the idler shaft, bearings spacer and shims on the idler shaft.
2. Clamp the large end of the shaft in a vise (Fig. 17).
3. Using a suitable sleeve or short piece of pipe, assemble the locknut and washer on the shaft as shown (Fig. 17) and torque the locknut to installation Specification.
4. Using a dial indicator, check the end play between the bearing cones and cups. Tolerance should be 0 to 0.002 inch. Adjust this tolerance by adding or subtracting shims between the bearings and the bearing spacer.

TESTING

When diagnosing transmission problems, refer to the truck Diagnosis Manual for the detailed information on the items that could be causing the problem.

The following preliminary checks should be made before proceeding with other diagnosis checks.

MANUAL LINKAGE CHECKS

Correct manual linkage adjustment is necessary to position the manual valve for proper fluid pressure direction to the different transmission components. Improperly adjusted manual linkage may cause cross-leakage and subsequent transmission failure. Refer to Linkage Adjustments in Part 17-02 for detailed manual linkage adjustment procedures.

TRANSMISSION FLUID LEVEL CHECK

The automatic transmission is designed to operate with the oil level between the add and full mark on the dipstick at an operating temperature of 150 degrees F to 170 degrees F, and should be checked under these conditions. The operating temperature may be obtained by driving 15 to 20 miles of city type driving with the outside temperature above 50 degrees F. If the transmission is not at an operating temperature of 150 degrees F to 170 degrees F and it becomes necessary to check the fluid level, the transmission may be checked at 70 degrees to 95 degrees F. Check the fluid level as follows:

Transmission at Operating Temperature (150 Degrees F to 170 Degrees F)

1. With transmission in Park P position, engine at curb idle rpm, foot brakes applied and vehicle on level surface, move the transmission selector lever through each range, allowing time in each range to engage transmission, return to Park P position, and apply parking brake. **Do not turn off the engine during the fluid level check.**
2. Clean all dirt from the transmission fluid dipstick cap before removing the dipstick from the filler tube.
3. Pull the dipstick out of the tube, wipe it clean, and push it all the way

back into the tube. Be sure it is fully seated.

4. Pull the dipstick out of the tube again and check the fluid level. The fluid level should be between the **add** and **full** mark. If additional fluid is required, add enough fluid through the filler tube to bring the level between the **add** and **full** marks on the dipstick. **Do not overfill the transmission,** as this will result in foaming and loss of fluid through the vent and possible transmission malfunction.
5. Install the dipstick, making sure it is fully seated in the tube.

Transmission at Room Temperature (70 Degrees F to 95 Degrees F)

1. With transmission in Park P position, engine at curb idle rpm, foot brakes applied and vehicle on level surface, move the transmission selector lever through each range allowing time in each range to engage transmission, return to Park P position and apply parking brake. **Do not turn off the engine during the fluid level check.**
2. Clean all dirt from the transmission fluid dipstick cap before removing the dipstick from the filler tube.
3. Pull the dipstick out of the tube, wipe it clean, and push it all the way back into the tube. Be sure it is fully seated.
4. Pull the dipstick out of the filler tube again and check the fluid level. For **C4 and FMX transmission,** the fluid level should be between the middle and top holes on the dipstick. If the fluid level is below the middle hole, add enough fluid through the filler tube to bring the level between the **middle hole** and the **add** mark. For **C6 transmissions,** the fluid level should be between the middle and top holes on the dipstick. If the fluid level is below the middle hole, add enough fluid through the filler tube to bring the level between the **middle and top** holes.
5. Install the dipstick, making sure it is fully seated in the tube.

If the transmission fluid level is correctly established at 70 degrees F to 95 degrees F, it will appear between the **add** and **full** marks on the dipstick when the transmission reaches an operating temperature of 150 degrees F to 170 degrees F. This fluid is set between the middle hole and the **add** mark for C4 and FMX transmissions and between the middle and top holes for the C6 transmission to allow for expansion of the fluid as transmission temperatures rise to normal operating temperatures of 150 degrees F to 170 degrees F. **Do not overfill;** however, if fluid is too low, extreme cold temperatures will contract the fluid, which may result in transmission malfunction.

FLUID AERATION CHECK

A fluid level that is too high will cause the fluid to become aerated: Aerated fluid will cause low control pressure, and the aerated fluid may be forced out the vent.

Check the transmission fluid level. Low fluid level can affect the operation of the transmission, and may indicate fluid leaks that could cause transmission damage.

TRANSMISSION FLUID LEAKAGE CHECKS

Check the speedometer cable connection at the transmission. Replace the rubber seal if necessary.

On an FMX transmission, inspect the governor inspection plate for leakage. Install a new gasket if needed.

Leakage at the oil pan gasket often can be stopped by tightening the attaching bolts to the proper torque. If necessary, replace the gasket.

Check the fluid filler tube connection at the transmission case or pan. If leakage is found here, install a new O-ring or tighten the fitting to the specified torque.

Check the fluid lines and fittings between the transmission and the cooler in the radiator tank for looseness, wear, or damage. If leakage cannot be stopped by tightening a fitting, replace the damaged parts.

Check the engine coolant in the radiator. If transmission fluid is present in the coolant, the cooler in the radiator is probably leaking.

The cooler can be further checked for leaks by disconnecting the lines from the cooler fittings and applying 50-75 psi air pressure to the fittings. Remove the radiator cap to relieve the pressure build up at the exterior of the oil cooler tank. If the cooler is leaking and will not hold pressure, the cooler must be replaced. Cooler replacement is described in the Cooling System Section of Group 27.

If leakage is found at either the downshift control lever shaft or the manual lever shaft, replace either or both seals.

Inspect the pipe plug on the left side of the transmission case at the front. If the plug shows leakage, torque the plug to specifications. If tightening does not stop the leaks, replace the plug. On a C6 transmission, a TV pressure plug is also provided on the right rear side of the case.

When a converter drain plug leaks, remove the drain plug with a six-point wrench. Coat the threads with FoMoCo Perfect Seal Sealing Compound or its equivalent, and install the plug. Torque the drain plug to specification. **Fluid leakage from the converter housing may be caused by engine oil leaking past the rear main bearing or from oil gallery plugs, or power steering oil leakage**

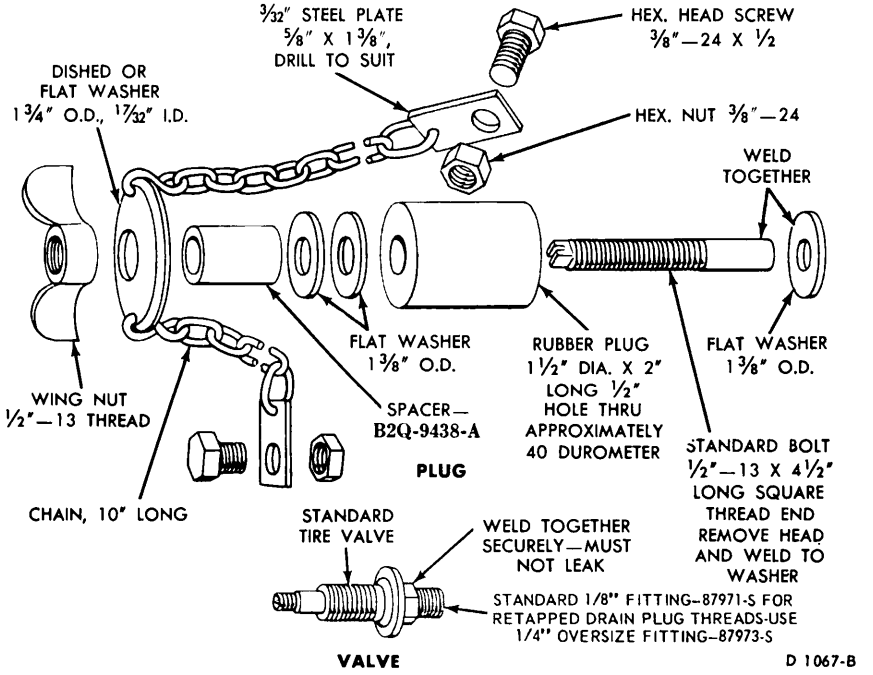

FIG. 2 Converter Leak Checking tool

from steering system. Be sure to determine the exact cause of the leak before repair procedures are started.

Oil-soluble aniline or fluorescent dyes premixed at the rate of 1/2 teaspoon of dye powder to 1/2 pint of transmission fluid have proved helpful in locating the source of the fluid leakage. Such dyes may be used to determine whether an engine oil or transmission fluid leak is present or if the fluid in the oil cooler leaks into the engine coolant system. A black light, however, must be used with the fluorescent dye solution.

CONVERTER LEAKAGE CHECK

If there are indications that the welds on the torque converter are leaking, the converter will have to be removed and the following check made before the unit is replaced.

A leak checking tool (Fig. 2) can be made from standard parts. The tool can be used to check all converters.

1. Install the plug in the converter (Fig. 3) and expand it by tightening the wing nut. Attach the safety chains.
2. Install the air valve in the drain plug hole.
3. Introduce air pressure into the converter. Check the pressure with a tire gauge and adjust it to 20 psi.
4. Place the converter in a tank of water. Observe the weld areas for bubbles. If no bubbles are observed, it may be assumed that the welds are not leaking.

ENGINE IDLE SPEED CHECK

Check and, if necessary, adjust the engine idle speed, using the procedure given in Group 24.

If the idle speed is too low, the engine will run roughly. An idle speed that is too high will cause the vehicle to creep, have harsh engagements and harsh closed-throttle downshifts.

ANTI-STALL DASHPOT CLEARANCE CHECK

After the engine idle speed has been properly adjusted, check the anti-stall dashpot clearance. Follow the procedure given in Group 24 for checking and adjusting this clearance.

CONTROL PRESSURE CHECK

When the vacuum diaphragm unit is operating properly and the downshift linkage is adjusted properly, all the transmission shifts (automatic and kickdown) should occur within the road speed limits specified in the Specifications.

If the shifts do not occur within limits or the transmission slips during shift point, use the following procedure to determine whether the engine, transmission, linkage, vacuum diaphragm unit or valve body is causing the condition.

1. Using the automatic transmission tester (Fig. 4), attach the tachometer to the engine and the vacuum gauge to the transmission vacuum line at the vacuum unit (Fig. 5).

On vehicles equipped with a dual area diaphragm (DAD), check the control pressure at 10 inches of vacuum by removing the exhaust gas recirculation (EGR) control hose from the diaphragm and plugging the hose. **Do not plug the EGR port in the diaphragm; this port must be left open to atmospheric pressure.** When checking the control pressure at stall and idle, keep the hose connected.

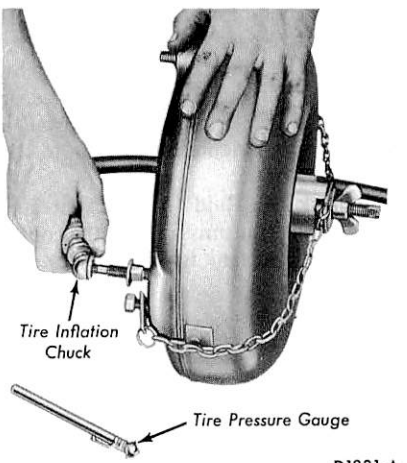

FIG. 3 Converter Leak Checking tool Installation

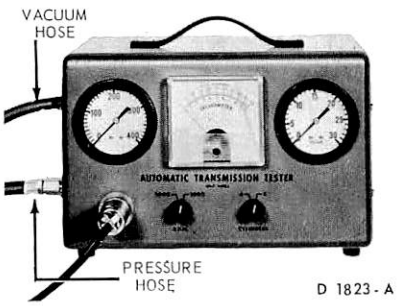

FIG. 4 Rotunda ARE-29-05 Automatic Transmission Tester

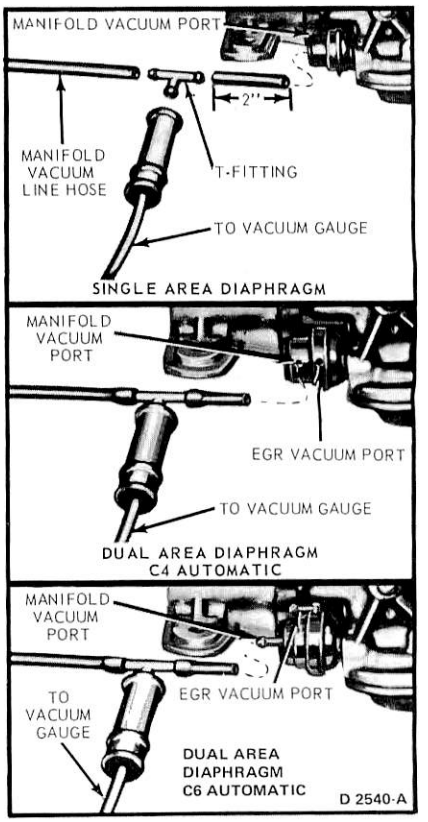

FIG. 5 Typical Vacuum Test Line Connections

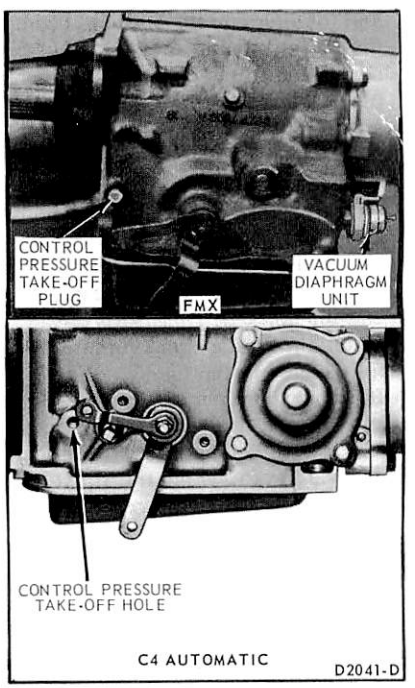

FIG. 6 Typical Vacuum Diaphragm and Control Pressure Connecting Point

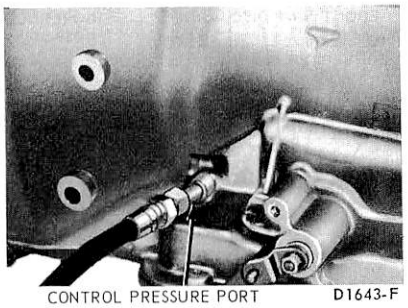

FIG. 7 Control Pressure Connecting Point-C6 Transmission

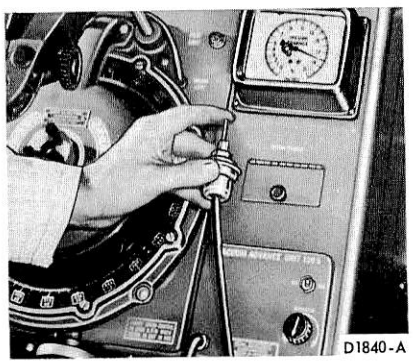

FIG. 8 Testing Transmission Vacuum Unit for Leakage

2. Attach the pressure gauge to the control pressure outlet at the transmission (Figs. 6 and 7).
3. Firmly apply the parking brake and start the engine.
4. Adjust the engine idle speed to the specified rpm. If the engine idle speed cannot be brought within limits by adjustment at the carburetor idle adjustment screw, check the throttle and downshift linkage for a binding condition. If the linkage is satisfactory, check for vacuum leaks in the transmission diaphragm unit (Fig. 8) and its connecting tubes and hoses. Check all other vacuum operated units (such as the power brake) for vacuum leaks.

VACUUM DIAPHRAGM CHECK

To check the vacuum unit for diaphragm leakage, remove the unit from the transmission. Use a distributor tester equipped with a vacuum pump (Fig. 8). Set the regulator knob so that the vacuum gauge reads 18 inches with the end of the vacuum hose blocked off.

Then, on single area diaphragms, connect the vacuum hose to the manifold vacuum port as shown in Fig. 8. On dual area diaphragms, connect the vacuum hose to the EGR port leaving the manifold vacuum port open to the atmosphere. If the gauge still reads 18 inches, the vacuum unit diaphragm is not leaking. As the hose is removed from the transmission vacuum unit, hold a finger over the end of the control rod. When the hose is removed, the internal spring of the vacuum unit should push the control rod outward. If the vacuum diaphragm needs replacing, install a new unit that has been released for service. Refer to the specification section for vacuum diaphragm assembly identification.

STALL TEST

Start the engine to allow it to reach its normal temperature. Apply both the parking and service brakes while making tests.

The stall test is made in D, 2, 1 or R, at full throttle to check engine performance, converter clutch operation or installation, and the holding ability of the forward clutch, reverse-high clutch and low-reverse band and the gear train one-way clutch. **While making this test, do not hold the throttle open for more than five seconds at a time.** Then move the selector lever to Neutral and run engine at 1000 rpm for about 15 seconds to cool the converter before making the next test. If the engine speed recorded by the tachometer exceeds the maximum limits shown in the Specifications, release the accelerator immediately because clutch or band slippage is indicated.

SHIFT POINT CHECKS

Check the minimum throttle upshifts in D. The transmission should start in first gear, shift to second, and then shift to third, within the shift points specified in the specifications.

While the transmission is in third gear, depress the accelerator pedal through the detent (to the floor). The transmission should shift from third to second or third to first, depending on the vehicle speed.

Check the closed throttle downshift from third to first by coasting down from about 30 mph in third gear. The shift should occur within the limits specified in the specifications.

When the selector lever is at 2, the transmission can operate only in second gear.

With the transmission in third gear and road speed over 30 mph, the transmission should shift to second gear when the selector lever is moved from D to 2 to 1. When the same manual shift is made below about 25 mph, the transmission will shift from second or

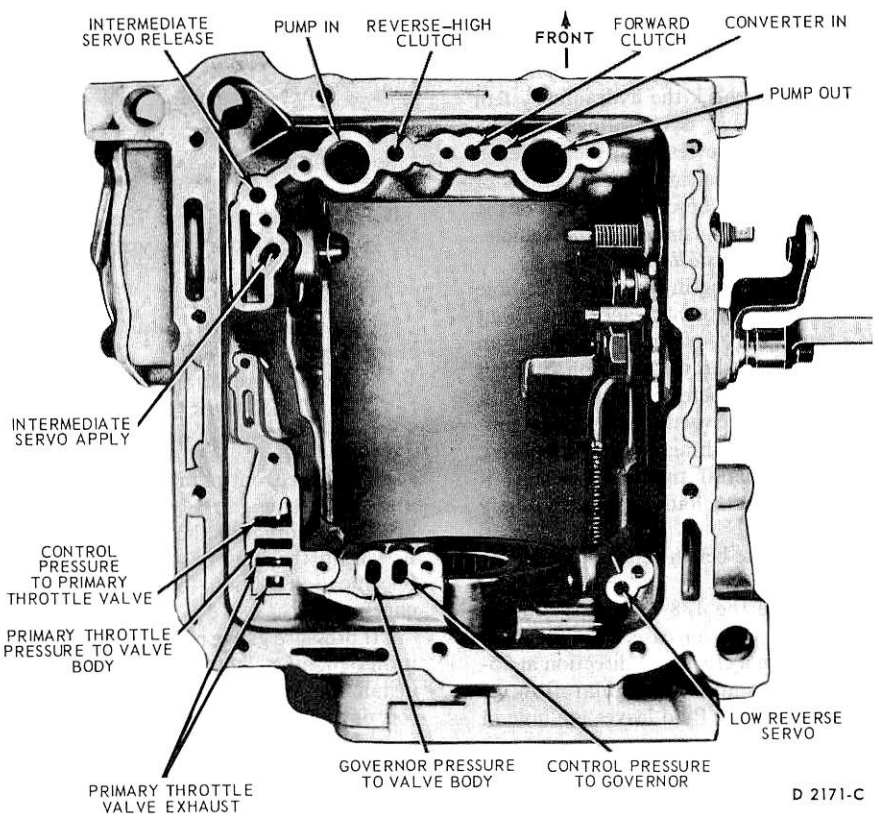

FIG. 9 Case Fluid Passage Hole Identification—C4 Automatic

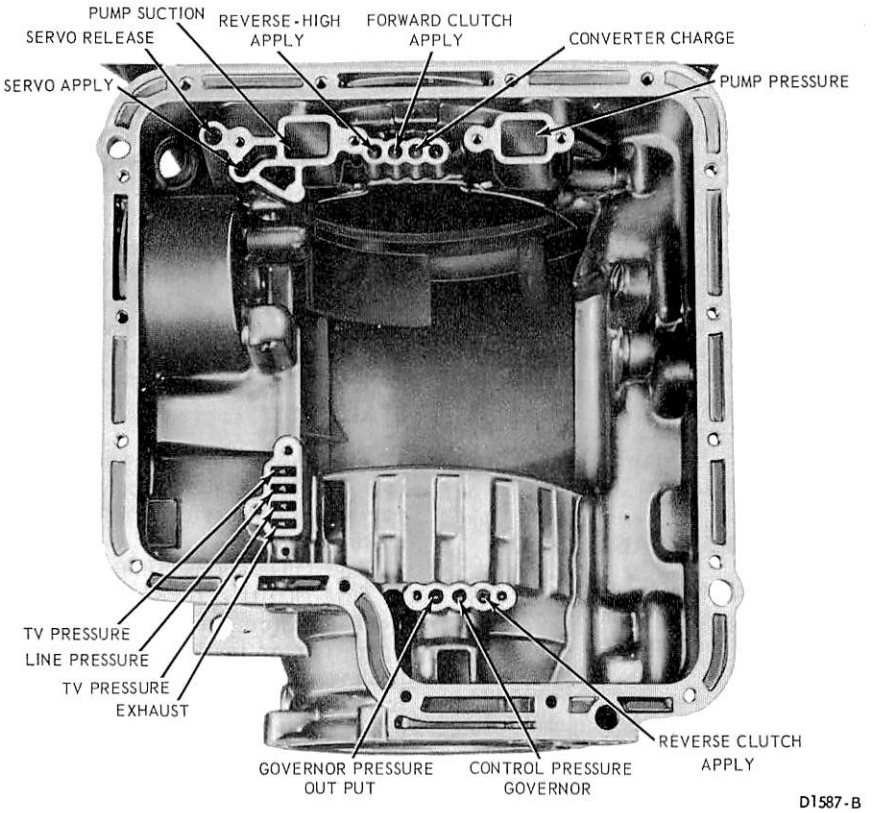

FIG. 10 Case Fluid Passage Hole Identification—C6 Automatic

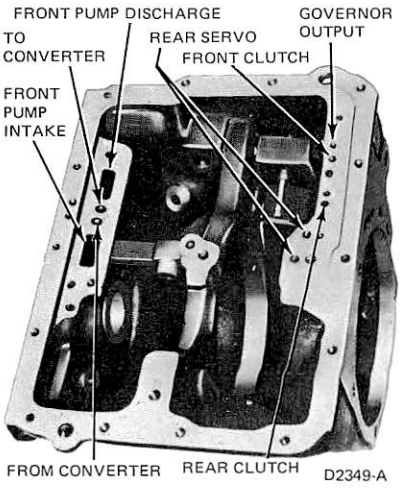

FIG. 11 Case Fluid Passage Hole Identification—FMX Automatic

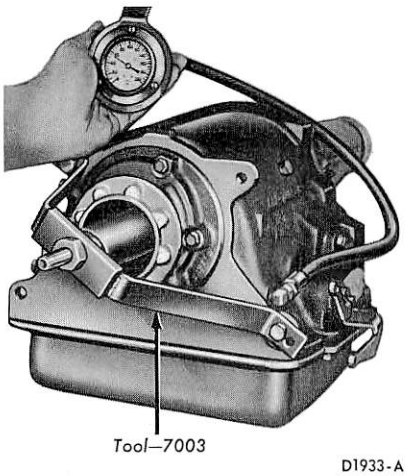

FIG. 12 Bench Testing Tool Installation—Typical

third to first. **This check will determine if the governor pressure and shift control valves are functioning properly.**

During the shift point check operation, if the transmission does not shift within specifications or certain gear ratios cannot be obtained, refer to the Diagnosis Manual to resolve the problem.

AIR PRESSURE CHECKS

A NO DRIVE condition can exist, even with correct transmission fluid pressure, because of inoperative clutches or bands. On automatic transmissions, an erratic shift could be caused by a stuck governor valve. The inoperative units can be located through a series of checks by substituting air pressure for the fluid pressure to determine the location of the malfunction.

To make the air pressure checks, drain the transmission fluid and remove the oil pan and the control valve body assembly. The inoperative units can be located by introducing air pressure into the various transmission case passages (Figs. 9, 10 or 11).

HYDRAULIC SYSTEM BENCH TESTS (FMX TRANSMISSIONS)

After the transmission has been assembled and is ready for installation in the vehicle, check the hydraulic system to make sure it is operating properly. These hydraulic tests can be made on the bench so that most malfunctions of the system can be corrected before the transmission is installed in the vehicle.

Testing Tool Installation

1. Install a plug in the filler tube hole in the case or pan, and pour about four quarts of clean transmission fluid into the transmission through the speedometer gear opening.
2. Remove the vacuum diaphragm unit and the diaphragm unit control rod, and reinstall the vacuum unit if these parts had been previously installed.
3. Install the bench testing tool on the transmission.
4. Remove the 1/8 inch pipe plug at the transmission case. Turn the front pump in a clockwise direction at 75-100 rpm until a regular flow of transmission fluid leaves the hole in the transmission case. This operation bleeds the air from the pump.
5. Install the pressure gauge (77820 or T57L-77820-A) as shown in Fig. 12.

Pressure Tests

Turn the front pump at 75-100 rpm and note the gauge readings. The pressure readings on the bench test must be within the limits as outlined in the Specification Section, for the engine idle check.

If pressure gauge readings are within limits in all selector lever positions, install the vacuum diaphragm control rod unit.

REMOVAL AND INSTALLATION

VACUUM DIAPHRAGM

REMOVAL AND INSTALLATION

1. Disconnect the hoses from the vacuum unit.
2. On C4 and C6 transmissions, remove the vacuum unit retaining bracket bolt and bracket (Fig. 13). Do not pry or bend the bracket. Pull the unit from the transmission case.

On an FMX transmission, remove the vacuum unit with the tool shown in Fig. 14.

3. Remove the control rod.
4. Install the vacuum unit control rod in the case.
5. On C4 and C6 transmissions, push the vacuum unit into the case and secure with the retaining bracket and bolt. Tighten the bolt 28-40 ft-lbs on C4 transmissions and 12-16 ft-lbs on C6 transmissions.

On an FMX transmission, thread the vacuum unit into the case and using a torque wrench with the tool shown in Fig. 14, tighten the unit to 15-23 ft-lbs torque.

6. Install the vacuum unit hoses to their respective connectors.

TRANSMISSION FLUID DRAIN AND REFILL

Normal maintenance and lubrication requirements do not necessitate periodic automatic transmission fluid changes.

If a major repair, such as a clutch band, bearing, etc., is required in the transmission, it will have to be removed for service. At this time the converter, transmission cooler and cooler lines must be thoroughly flushed to remove any dirt.

When filling a dry transmission and converter, install five quarts of fluid in C4 transmissions and eight quarts in C6 and FMX transmissions. Then, check the fluid level following the room temperature checking procedures described in this Part.

Following are the procedures for partial drain and refill due to in-vehicle repair operation.

C4 or MX Transmissions

1. Disconnect the fluid filler tube from the transmission oil pan to drain the fluid.
2. When the fluid has stopped draining from the transmission, remove and thoroughly clean the pan and the screen. Discard the pan gasket.
3. Place a new gasket on the pan, and install the pan on the transmission.
4. Connect the filler tube to the pan and tighten the fitting securely.
5. Add three quarts of fluid to the transmission through the filler tube.
6. Check the fluid level following the room temperature checking procedures described in this Part.

C6 or FMX Transmission

1. Raise the vehicle on a hoist or jack stands.
2. Place a drain pan under the transmission.
3. Loosen the pan attaching bolts to drain the fluid from the transmission.
4. After the fluid has drained to the level of the pan flange, remove the rest of the pan bolts working from the rear and both sides of the pan to allow it to drop and drain slowly.
5. When the fluid has stopped draining from the transmission, remove and thoroughly clean the pan and the screen. Discard the pan gasket.
6. Place a new gasket on the pan, and install the pan on the transmission
7. Add three quarts of fluid to the transmission through the filler tube.
8. Check the fluid level following the room temperature checking procedures described in this Part.

OIL COOLER TUBE REMOVAL AND INSTALLATION

When fluid leakage is found at the oil cooler, the cooler must be replaced. Cooler replacement is described in the Cooling System Section of Group 27.

When one or more of the fluid cooler steel tubes must be replaced, each replacement tube must be fabricated from the same size steel tubing as the original line.

Using the old tube as a guide, bend the new tube as required. Add the necessary fittings, and install the tube.

After the fittings have been tightened, add fluid as needed, and check for fluid leaks.

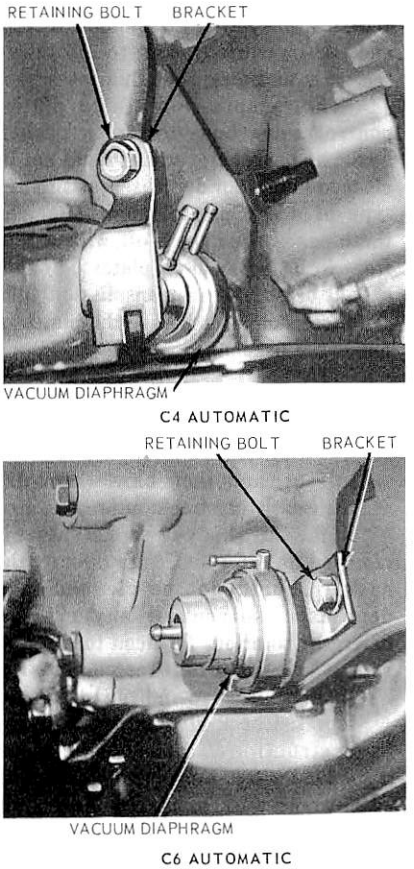

FIG. 13 Vacuum Diaphragm Installed-C4 and C6 Transmission

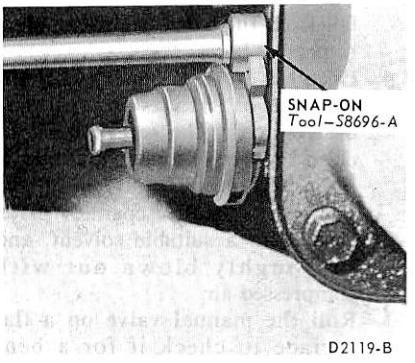

FIG. 14 Removing or Installing Vacuum Diaphragm FMX Transmission

CLEANING AND INSPECTION

TRANSMISSION

Clean the parts with suitable solvent and use moisture-free air to dry off all the parts and clean out fluid passages.

The composition clutch plates, control valve body-to-screen gasket, bands and synthetic seals should not be cleaned in a vapor degreaser or with any type of detergent solution. To clean these parts, wipe them off with a lint-free cloth. New clutch plates or bands should be soaked in transmission fluid for fifteen minutes before the plates or bands are assembled.

CONTROL VALVE BODY

1. Clean all parts thoroughly in clean solvent, and then blow them dry with moisture-free compressed air.

If the valve body-to-screen gasket is removed on a C4 or C6 Automatic, the gasket should not be cleaned in a degreaser, solvent or any type of detergent solution. To clean the gasket, wipe it off with a lint-free cloth.

2. Inspect all valve and plug bores for scores. Check all fluid passages for obstructions. Inspect the check valve for free movement. Inspect all mating surfaces for burrs or distortion. Inspect all plugs and valves for burrs or scores. **Crocus cloth can be used to polish valves and plugs if care is taken to avoid rounding the sharp edges of the valves and plugs.**
3. Inspect all springs for distortion. Check all valves and plugs for free movement in their respective bores. Valves and plugs, when dry, must fall from their own weight in their respective bores.
4. On a C6 transmission, inspect the separator plate screen for obstructions. The screen must be clean and free of foreign material. If it is contaminated, it should be removed from the separator plate, cleaned in a suitable solvent, and thoroughly blown out with compressed air.
5. Roll the manual valve on a flat surface to check it for a bent condition.

INTERMEDIATE SERVO (C4 AND C6 TRANSMISSIONS)

1. Inspect the servo bore for cracks and the piston bore and the servo piston stem for scores. Check fluid passages for obstructions. Replace seals that are damaged.
2. Check the servo spring and servo band strut(s) for distortion.
3. Inspect the cover seal and gasket cover sealing surface for damage.

LOW-REVERSE SERVO (C4 TRANSMISSION)

1. Inspect the servo body for cracks and the piston bore for scores.
2. Check the fluid passages for obstructions.
3. Inspect the band and the struts for distortion. Inspect the band ends for cracks.
4. Inspect the servo spring for distortion.
5. Inspect the band lining for excessive wear and bonding to the metal band.
6. Replace seals that are damaged.

FRONT SERVO (FMX TRANSMISSIONS)

1. Inspect the servo bore for cracks and the piston bore and the servo piston stem for scores. Check fluid passages for obstructions. Replace seals that are damaged.
2. Check the actuating lever for free movement, and inspect it for wear. If necessary to replace the actuating lever or shaft, remove the retaining pin and push the shaft out of the bracket.

Inspect the adjusting screw threads and the threads in the lever for damage.

3. Check the servo spring and servo band strut(s) for distortion.

REAR SERVO (FMX TRANSMISSION)

1. Inspect the servo body for cracks and the piston bore for scores.
2. Check the fluid passages for obstructions.
3. Inspect the band and the struts for distortion. Inspect the band ends for cracks.
4. Inspect the servo spring for distortion.
5. Inspect the band lining for excessive wear and bonding to the metal band.
6. Check the servo body to case mating surface for burrs. Check the accumulator piston and the check valve for freedom of movement. Check the actuating lever socket for scores.
7. Replace seals that are damaged.

EXTENSION HOUSING

1. Inspect the housing for cracks. Inspect the gasket surface for burrs or warpage. Check for leakage around the governor inspection cover and gasket on an FMX transmission. If leakage is found, install a new gasket.
2. Inspect the bushing for scores or wear.
3. Inspect the rear seal for hardness, cracks, or wear. If the seal shows wear or deterioration, replace the seal.
4. Inspect the seal counterbore and remove all burrs and scores with crocus cloth.

GOVERNOR

1. Inspect the governor valves and bores for scores. Minor scores may be removed from the valves with crocus cloth. Replace the governor if the valves or body is deeply scored.
2. On an FMX transmission, inspect the governor screen for obstructions. The screen must be clean and free of foreign material. If it is contaminated, it should be cleaned in a suitable solvent and thoroughly blown out with compressed air.
3. Check for free movement of the valves in the bores. The valves should slide freely of their own weight in the bores when dry. Inspect fluid passages in the valve body and counterweight for obstructions. **All fluid passages must be clean.**
4. Inspect the mating surfaces of the governor body and governor distributor (C4 or C6 Automatic) for burrs and distortion. Mating surfaces must be smooth and flat.
5. Check the mating surface of the governor valve and the counterweight on an FMX transmission for burrs or scratches.

PRESSURE REGULATOR (FMX TRANSMISSION)

1. Inspect the regulator body and cover mating surface for burrs.
2. Check all fluid passages for obstructions.
3. Inspect the control pressure and converter pressure valves and bores for burrs and scores. Remove all burrs carefully with crocus cloth.
4. Check free movement of the valves

in their bores. The valves should fall freely into the bores when both the valve and bore are dry.
5. Inspect the valve springs and spacers for distortion.

FRONT PUMP

1. Inspect the mating surfaces of the pump body and cover for burrs.
2. Inspect the drive and driven gear bearing surface for scores, and check the gear teeth for burrs.
3. Check the fluid passages for obstructions.
4. If any parts are found defective, replace the pump as a unit. Minor burrs and scores may be removed with crocus cloth.
5. On a C6 transmission, check the large seal ring groove of the pump body for damage. Check the gasket mating surface of the pump body for damage.

REAR PUMP (FMX TRANSMISSION)

1. Remove the drive gear from the pump body.
2. Inspect the gear pocket of the pump body for scores or pitting.
3. Inspect the inner bushing and the drive gear bearing surface for scores.
4. Check all fluid passages for obstructions, and check mating surfaces and gasket surfaces of the pump body and cover for burrs.
5. Inspect the pump cover bearing surface for scores. Minor burrs or scores may be removed with crocus cloth.

REVERSE-HIGH CLUTCH (C4 AND C6 TRANSMISSIONS)

1. Inspect the drum band surface, the bushing, and thrust surfaces for scores. Minor scores may be removed with crocus cloth. **Badly scored parts must be replaced.**

Inspect the clutch piston bore and the piston inner and outer bearing surfaces for scores. Check the air bleed ball valve in the clutch piston for free movement. Check the orifice to make sure it is not plugged.

2. Check the fluid passages for obstructions. All fluid passages must be clean and free of obstructions.
3. Inspect the clutch plates for wear and scoring and check the plates for fit on the clutch hub serrations. Replace all plates that are badly scored, worn or do not fit freely in the hub serrations.
4. Inspect the clutch pressure plate for scores on the clutch plate bearing surface. Check the clutch release spring(s) for distortion.

FORWARD CLUTCH (C4 AND C6 TRANSMISSIONS)

1. Inspect the clutch cylinder thrust surfaces, piston bore, and clutch plate serrations for scores or burrs. Minor scores or burrs may be removed with crocus cloth. Replace the clutch cylinder if it is badly scored or damaged.
2. Check the fluid passage in the clutch cylinder for obstructions. Clean out all fluid passages. Inspect the clutch piston for scores and replace if necessary. Inspect the piston check ball for freedom of movement and proper seating (Fig. 15).
3. Check the clutch release spring for distortion and cracks. Replace the spring if it is distorted or cracked.
4. Inspect the composition and the steel clutch plates and the clutch pressure plate for worn or scored bearing surfaces. Replace all parts that are deeply scored.
5. On C4 transmissions, check the clutch plates for flatness and fit on the clutch hub serrations. Discard any plate that does not slide freely on the serrations or that is not flat.
6. Check the clutch hub thrust surfaces for scores and the clutch hub splines for wear.
7. Check the splines on the turbine shaft for wear and replace the shaft if the splines are excessively worn. Inspect the bushing in the turbine shaft for scores. Check the input shaft for damaged or worn splines.

REAR CLUTCH (FMX TRANSMISSION)

1. Inspect the drum band surface, the bushing, and thrust surfaces for scores. Minor scores may be removed with crocus cloth. **Badly scored parts must be replaced. Inspect the clutch piston bore and the piston inner and outer bearing surfaces for scores. Check the air bleed ball valve in the clutch piston for free movement. Check the orifice to make sure it is not plugged.**
2. Check the fluid passages for obstructions. All fluid passages must be clean and free of obstructions.
3. Inspect the clutch plates for wear and scoring and check the plates for fit on the clutch hub serrations. Replace all plates that are badly scored, worn or do not fit freely in the hub serrations.
4. Inspect the clutch pressure plate for scores on the clutch plate bearing surface. Check the clutch release spring(s) for distortion.
5. Inspect the needle bearing for worn rollers.

FRONT CLUTCH (FMX TRANSMISSION)

1. Inspect the clutch cylinder thrust surfaces, piston bore, and clutch plate serrations for scores or burrs. Minor scores or burrs may be removed with crocus cloth. Replace the clutch cylinder if it is badly scored or damaged.
2. Check the fluid passage in the clutch cylinder for obstructions. Clean out all fluid passages. Inspect the clutch piston for scores and replace if necessary. Inspect the piston check ball for freedom of movement and proper seating (Fig. 15).
3. Check the clutch release spring for distortion and cracks. Replace the spring if it is distorted or cracked.
4. Inspect the composition and the steel clutch plates and the clutch pressure plate for worn or scored bearing surfaces. Replace all parts that are deeply scored.
5. Check the clutch plates for flatness and fit on the clutch hub serrations. Discard any plate that does not slide freely on the serrations or that is not flat.
6. Check the clutch hub thrust surfaces for scores and the clutch hub splines for wear.

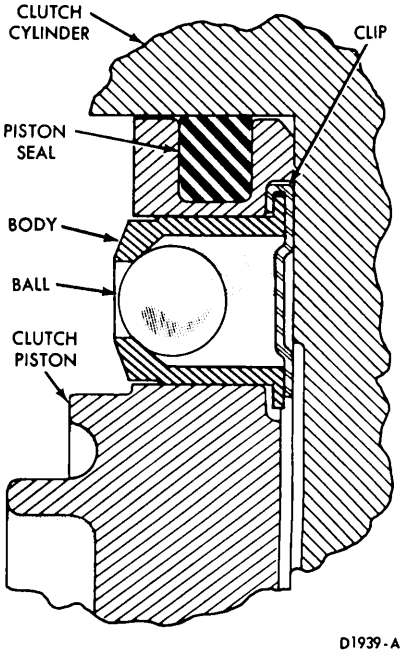

FIG. 15 Clutch Piston Check Valve

7. Inspect the turbine shaft bearing surfaces for scores. If excessive clearance or scores are found, discard the unit.
8. Check the splines on the turbine shaft for wear and replace the shaft if the splines are excessively worn. Inspect the bushing in the turbine shaft for scores.

ONE-WAY CLUTCH

1. Inspect the outer and inner races for scores or damaged surface area where the rollers contact the races. If the outer race on the C6 transmission is damaged on the lowreverse clutch hub it must be replaced.
2. Inspect the rollers and springs for excessive wear or damage.
3. Inspect the spring and roller case for bent or damaged spring retainers.

PRIMARY SUN GEAR SHAFT (FMX TRANSMISSION)

1. Inspect the primary sun gear for broken or worn teeth. Inspect all thrust surfaces and journals for scores. Check all fluid passages (Fig. 16) for obstructions and leakage. Inspect the seal ring grooves for burrs.
2. Inspect the sun gear shaft splines for burrs and wear.
3. Check the fit of the seal rings in the grooves of the shaft. The rings should enter the grooves freely without bind.
4. Check the fit of the seal rings in their respective bores. A clearance of 0.002-0.009 inch should exist between the ends of the rings.
5. Install the seal rings on the shaft, and check for free movement in the grooves.

CONVERTER AND OIL COOLER

When internal wear or damage has occurred in the transmission, metal particles, clutch plate or band material may have been carried into the converter and oil cooler. These contaminants are a major cause of recurring transmission troubles and **MUST** be removed from the system before the transmission is put back into service.

Whenever a transmission has been disassembled to replace worn or damaged parts or because the valve body sticks from foreign material, the converter and oil cooler **MUST** be cleaned by using a mechanically agitated cleaner, such as Rotunda LRE-60081. Under **NO** circumstances should an attempt be made to clean converters or oil coolers by hand agitation with solvent.

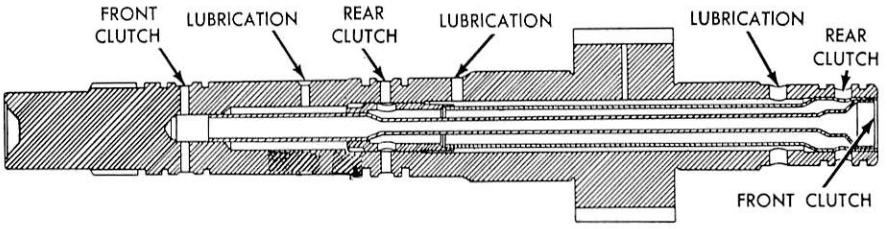

FIG. 16 Primary Sun Gear Shaft—Cross Sectional View

TURBINE AND STATOR END PLAY CHECK

A special tool (Fig. 17) must be used to check the condition of the converter. This special tool is used to check the turbine and stator end play and the operation of the one-way stator clutch.

1. Insert the tool (Fig. 18) into the converter pump drive hub until it bottoms.
2. Install the guide over the converter pump drive hub.
3. Expand the split fiber bushing in the turbine spline by tightening the adjusting nut. Tighten the adjusting nut until the tool is securely locked into the spline.
4. Attach a dial indicator to the tool (Fig. 18). Position the indicator button on the converter pump drive hub, and set the dial face at 0 (zero).
5. Lift the tool upward as far as it will go and note the indicator reading. The indicator reading is the total end play which the turbine and stator share. If the total end play exceeds the limits specified in the Specifications, replace the converter unit.
6. Loosen the adjusting nut to free the split bushing, and then remove the tool from the converter.

STATOR ONE-WAY CLUTCH CHECK

1. Install the stator outer race holding tool in one of the four holes provided in the stator (Fig. 19).
2. Insert the tool in the converter pump drive hub so the splines engage the one-way clutch inner race (Fig. 19).
3. Place the guide over the tool to keep the stator race holding tool from turning. Then, hold the guide stationary and place a torque wrench on the tool (Fig. 19). The tool (and stator inner race) should turn freely clockwise (from the pump drive hub inside the converter). It should lock up and hold a 10 ft-lb pull when the wrench is turned counterclockwise. Try the clutch for lock up and hole in at least five different locations around the converter.
4. If the clutch fails to lock up and hold a 10 ft-lb torque, replace the converter unit.

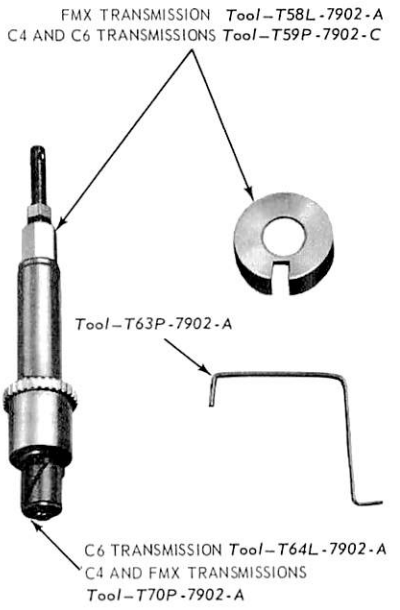

FIG. 17 Converter Checking Tool

STATOR TO IMPELLER INTERFERENCE CHECK

1. Position the front pump assembly on a bench with the spline end of the stator shaft pointing up (Fig. 20).

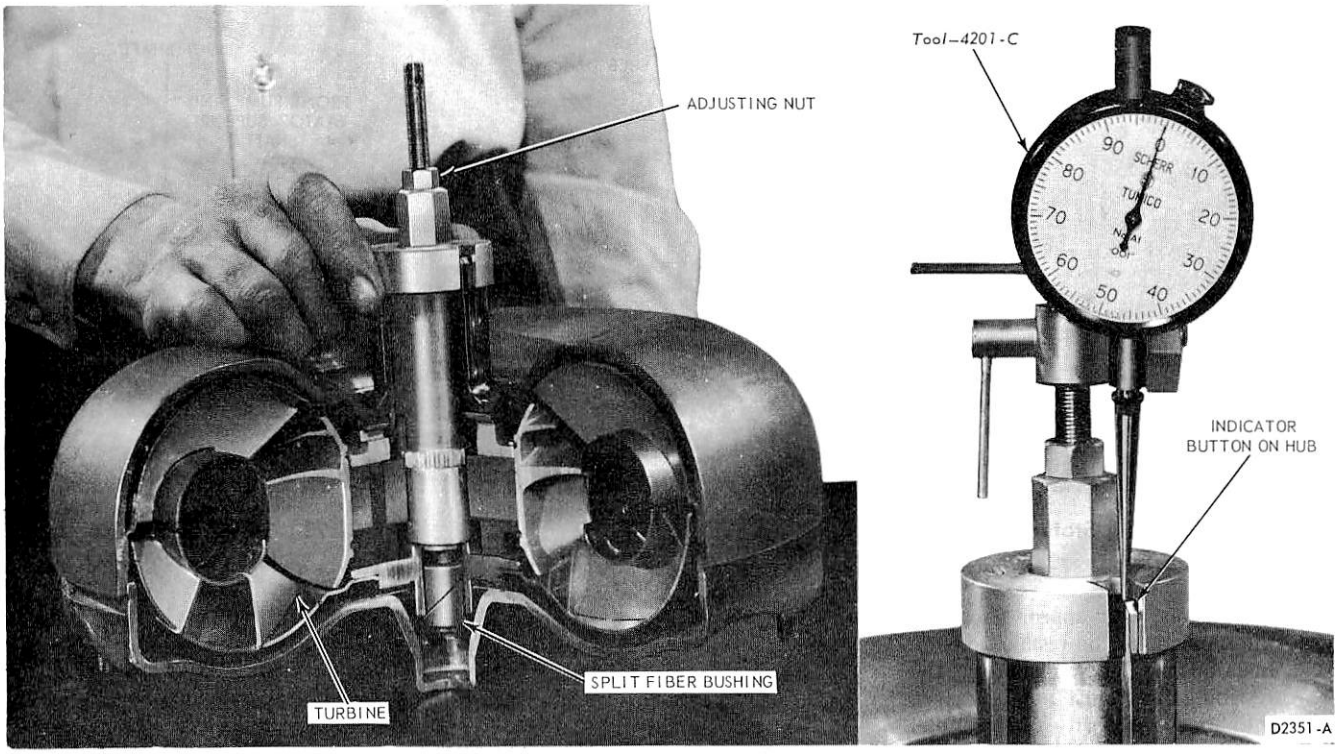

FIG. 18 Checking Turbine and Stator End Play

2. Mount a converter on the pump so that the splines on the one-way clutch inner race engage the mating splines of the stator support, and the converter hub engages the pump drive gear.
3. While holding the pump stationary, try to rotate the converter counterclockwise. The converter should rotate freely without any signs of interference or scraping within the converter assembly.
4. If there is an indication of scraping, the trailing edges of the stator blades may be interfering with the leading edges of the impeller blades. In such cases, replace the converter.

STATOR TO TURBINE INTERFERENCE CHECK

1. Position the converter on the bench front side down.
2. Install a front pump assembly to engage the mating splines of the stator support and stator, and pump drive gear lugs.
3. Install the input shaft, engaging the splines with the turbine hub (Fig. 21).
4. While holding the pump stationary, attempt to rotate the turbine with the input shaft. The turbine should rotate freely in both directions without any signs of interference or scraping noise.
5. If interference exists, the stator front thrust washer may be worn, allowing the stator to hit the turbine. In such cases, the converter must be replaced.

The converter crankshaft pilot should be checked for nicks or damaged surfaces that could cause interference when installing the converter into the crankshaft. Check the converter front pump drive hub for nicks or sharp edges that would damage the pump seal.

OUTPUT SHAFT (FMX TRANSMISSION)

1. Inspect the thrust surfaces and journals for scores. Inspect the internal gear for broken or worn teeth.
2. Inspect the ring grooves for burrs.
3. Inspect the keyway and drive ball pocket for wear, and inspect the splines for burrs, twist or wear.
4. Inspect the external parking gear teeth for damage and the speedometer drive gear teeth for burrs.
5. If either the output shaft or ring gear has been replaced, place the assembled unit with the gear face down on the bench, push the shaft downward, and check the clearance between the top of the snap ring and its groove (Fig. 22). If this clearance exceeds 0.002 inch, replace the snap ring with a thicker ring to reduce the clearance to less than 0.002 inch. Selective snap rings are available in several thicknesses for this purpose.

DISTRIBUTOR SLEEVE (FMX TRANSMISSION)

1. Inspect the distributor sleeve for scores or excessive ring wear. Inspect the distributor sleeve passages for obstructions.
2. Check the fit of the fluid tubes in the distributors.

PLANET CARRIER AND CENTER SUPPORT (FMX TRANSMISSION)

1. Inspect the clutch outer race, inner race, band surface, pinion gears, bearings, and thrust washer (Fig. 23) for roughness.
2. Inspect the center support bushing for roughness.

PINION CARRIERS (C4 AND C6 TRANSMISSION)

Individual parts of the planet carriers are not serviceable.

1. The pins and shafts in the planet assemblies should be checked for loose fit and/or complete disengagement. Use a new planet assembly if either condition exists. Before installing a planet assembly, the shaft retaining pins should be checked for adequate staking. If

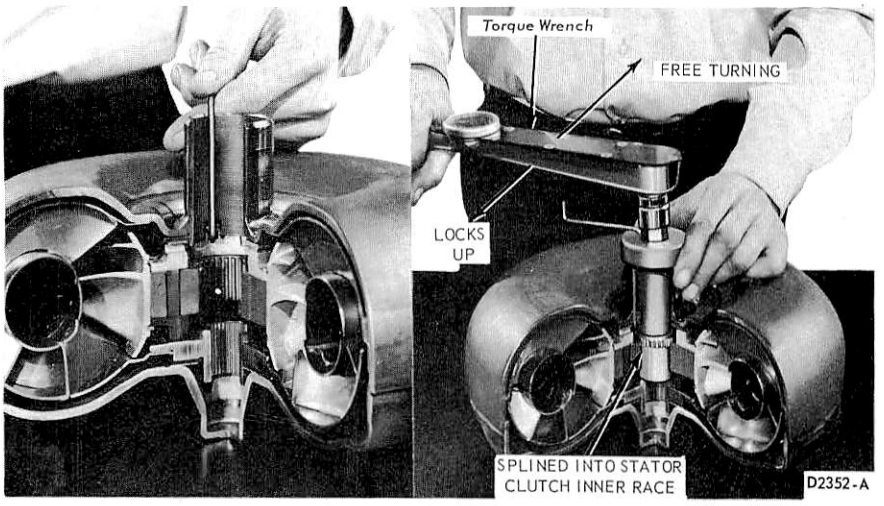

FIG. 19 Checking Stator One-Way Clutch

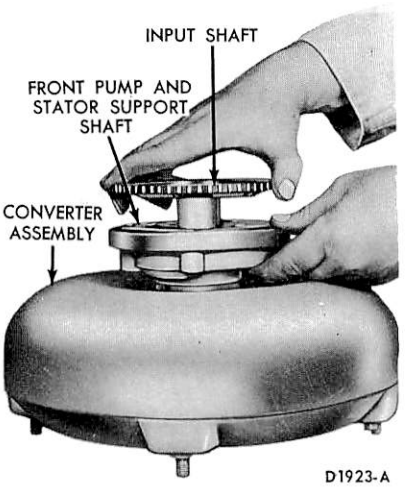

FIG. 21 Stator to Turbine Interference Check

staking does not appear adequate, the pins should be restaked before installation. When restaking, the retaining pins must not be driven into the carrier any further than 0.040 inch below the surface of the carrier.

2. Inspect the pinion gears for damaged or excessively worn teeth.
3. Check for free rotation of the pinion gears.

STATOR SUPPORT

1. Inspect the stator support splines for burrs and wear.
2. On a C4 or C6 Automatic transmission, check the oil ring grooves in the stator support for nicks, burrs or damaged edges.

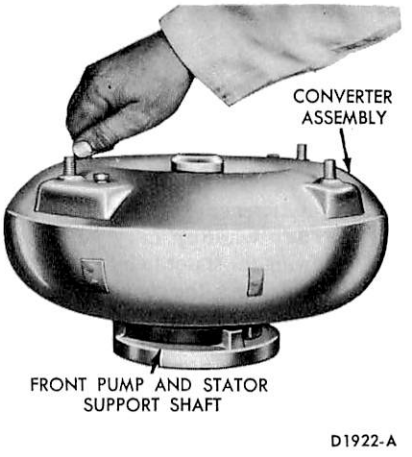

FIG. 20 Stator to Impeller Interference Check

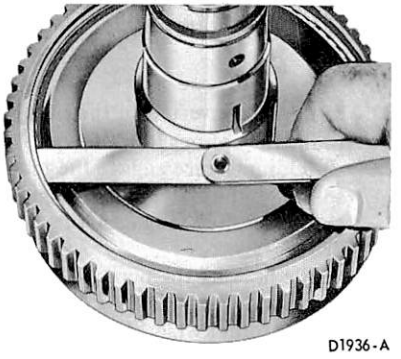

FIG. 22 Checking Output Shaft Snap Ring Clearance

CASE

Inspect the case for cracks and stripped threads. Inspect the gasket surfaces and mating surfaces for burrs. Check the vent for obstructions, and check all fluid passages for obstructions and leakage (Figs. 9, 10 and 11).

Inspect the case bushing for scores. Check all parking linkage parts for wear or damage.

If a transmission case thread is damaged, service kits may be purchased from local jobbers. To repair a damaged thread, the following procedures should be carefully followed.

1. Drill out the damaged threads **using the same drill size as the thread OD.** For example, use a 5/16 inch drill for a 5/16-18 thread.
2. Select the proper **special** tap and tap the drilled hole. The tap is marked for the size of the thread being repaired. Thus, the special tap marked 5/16-18 will not cut the same thread as a standard 5/16-18 tap. It does cut a thread large enough to accommodate the insert, and after the insert is installed, the original thread size (5/16-18) is restored.
3. Select the proper coil inserting tool. These tools are marked with the thread size being repaired. Place the insert on the tool and adjust the sleeve to the length of the insert being used.
   Press the insert against the face of the tapped hole. Turn the tool clockwise and wind the insert into the hole until the insert is 1/2 turn below the face.
4. Working through the insert, bend the insert tang straight up and down until it breaks off at the notch.
5. If the inserts are not properly installed, they can be removed with the extractor tool. Place the extractor tool in the insert so that the blade rests against the top coil 1/4 to 1/2 turn away from the end of the coil. Tap the tool sharply with a hammer so that the blade cuts into the insert. Exert downward pressure on the tool and turn it counterclockwise until the insert is removed.

ADJUSTMENTS

The transmission control linkage adjustments should be performed in the order in which they appear in this section of the manual. Before the linkage is adjusted, be sure the engine idle speed and anti-stall dashpot are properly adjusted. Refer to Group 24 for the procedure.

MANUAL LINKAGE ADJUSTMENTS

F-100-250-350, BRONCO AND ECONOLINE

1. With the engine stopped, place the transmission selector level in the D position and hold against the D stop.
2. Loosen the shift rod adjusting nut at point A (Fig. 1, 2 or 3).
3. Shift the manual lever at the transmission into the D position, second detent position from the back of the transmission.
4. With the transmission selector lever and manual lever in the D position, tighten the nut at point A to 12-18 ft-lbs torque (Fig. 1, 2 or 3). **Under no circumstances should the linkage be adjusted in any position other than the D position.**
5. Operate the shift lever in all positions to make certain that the manual lever at the transmission is in full detent in all gear ranges. Readjust the linkage if required.

P-350-400-500

1. With the engine stopped, disconnect the upper end of the manual shift rod from the shift lever (Fig. 4).
2. Position the selector lever so that the pointer is against the steering column stop in the N position.
3. Shift the manual lever on the transmission to the N position, fourth from the rear.
4. Rotate the trunnion on the manual shift rod until the pin can be easily inserted in the lever. Then, turn the trunnion two full turns counterclockwise to lengthen the rod.
5. Connect the trunnion to the shift lever.
6. As a final check, operate the shift lever in all positions to make certain that the manual lever at the transmission is in full detent in all gear ranges. Readjust manual shift rod if required, one turn at a time.
7. Adjust selector indicator to quandrant if necessary.

B-600-700 AND F-600

1. With the engine stopped, position the transmission selector lever in the D position.
2. Disconnect the shift cable clevis at the transmission manual lever (Fig. 5).
3. Move the transmission manual lever to the D position, second detent position from the front of the transmission.
4. With the transmission manual lever in the D position, adjust the clevis so that it freely enters into the hole of the manual lever.
5. Connect the clevis to the manual lever and secure with the flat washers, spring washer and cotter pin.
6. Operate the shift lever in all positions to make certain that the manual lever at the transmission is in full detent in all gear ranges. It may be necessary to readjust the clevis slightly to obtain the detent position in all drive ranges.

THROTTLE AND DOWNSHIFT LINKAGE ADJUSTMENTS

Adjusting the throttle linkage is important to be certain the throttle and downshift systems are properly adjusted. The downshift system should come in when the accelerator is pressed through detent, and not before detent. Refer to Group 24 for detailed throttle and downshift linkage adjustment procedures.

NEUTRAL START SWITCH ADJUSTMENT

F-100-250-350

1. Loosen the two neutral start switch attaching screws (Fig. 6).
2. Hold the selector lever against the neutral stop.
3. Move the sliding block on the neutral switch to the neutral position. Working from the rear side of the switch, insert an 0.091 inch diameter gauge pin (No. 43 drill) in the gauge pin hole (Fig. 6).
4. Slide the switch as required to permit the switch actuating lever to contact the switch sliding block.

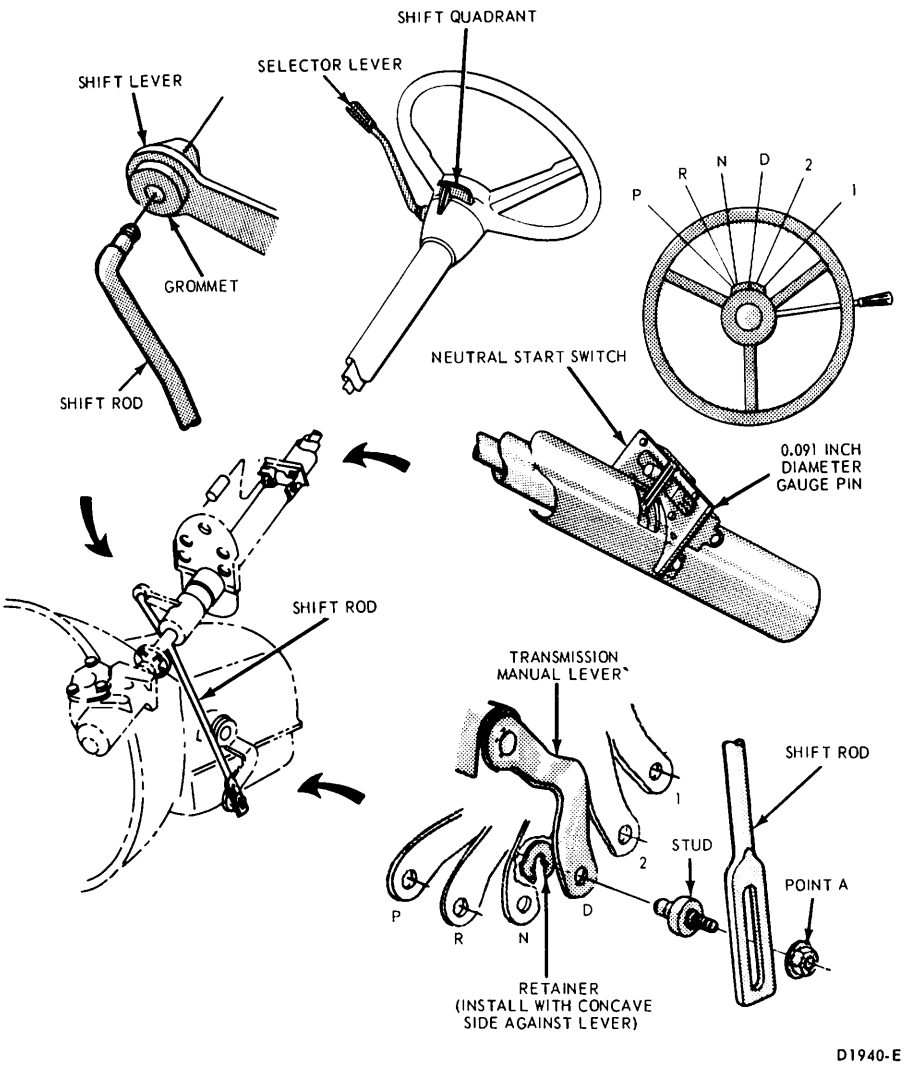

FIG. 1 Manual Linkage Adjustment—F-100-250-350

5. Tighten the two switch attaching screws and remove the gauge pin.
6. Check the operation of the switch. The engine should start only with the transmission selector lever in neutral and park.

ECONOLINE AND BRONCO

1. With the manual linkage properly adjusted, loosen the two switch attaching bolts (Fig. 7).
2. Place the transmission manual lever in neutral. Rotate the switch and insert the gauge pin (No. 43 drill shank end) into the gauge pin holes of the switch. The gauge pin has to be inserted a full 31/64 inch into the three holes of the switch (Fig. 7).
3. Torque the two neutral start switch attaching bolts to specification. Remove the gauge pin from the switch.
4. Check the operation of the switch. The engine should start only with the transmission selector lever in neutral or park.

P-350-400-500

1. Place the selector lever in neutral.
2. Loosen the two neutral start switch attaching screws.
3. Move the neutral start switch until the switch lever is in the neutral detent position (Fig. 8). Tighten the attaching screws.
4. Check the operation of the switch in each selector lever position. The engine should start only with the transmission selector lever in neutral or park.

B-600-700 AND F-600

Check the starter circuit at all selector lever positions. The circuit must be open at all positions except N (neutral). To adjust, loosen the neutral switch to bracket attaching screws (Fig. 9). Position the switch so that the starter circuit is closed when the selector lever is at N.

REMOVAL AND INSTALLATION

MANUAL SHIFT LINKAGE GROMMET REMOVAL AND INSTALLATION

The automatic transmission linkage systems make use of an oil impregnated plastic grommet to connect the various rods and levers. Whenever a rod is disconnected from a grommet type connector, the old grommet must be removed and a new one installed. Remove and install the grommet as follows:

1. Place the lower jaw of the tool between the lever and the rod (Fig. 10). Position the stop pin against the end of the control rod (Fig. 10) and force the rod out of the grommet. Remove the grommet from the lever by cutting off the large shoulder with a sharp knife. **The grommet must be removed from the lever and a new one installed each time the rod is disconnected.**
2. Before installing a new grommet, adjust the stop pin to 1/2 inch and coat the outside of the grommet with lubricant. Then, place the grommet on the stop pin and force it into the lever hole.Turn the grommet several times to be sure it is properly seated.
3. Readjust the stop pin to the height shown in Fig. 10. The pin height is determined by the length of the rod end which is to be installed into the grommet. If the pin height is not adjusted, the rod may be pushed too far through the grommet causing damage to the grommet retaining lip.
4. With the pin height properly adjusted, position the rod on the tool and force the rod into the grommet until the groove in the rod seats on the inner retaining lip of the grommet.

NEUTRAL START SWITCH REMOVAL AND INSTALLATION

F-100-250-350

1. Disconnect the neutral start switch wires at the plug connector.
2. Remove the two screws securing the neutral start switch to the steering column and remove the switch.
3. Position the neutral start switch on the steering column and install the two attaching screws.
4. Hold the selector lever against the neutral stop.
5. Move the sliding block on the neutral switch to the neutral position. Working from the rear side of the switch, insert an 0.091 inch diameter gauge pin (No. 43 drill) in the guage pin hole (Fig. 6).
6. Slide the switch as required to permit the switch actuating lever to contact the switch sliding block.
7. Tighten the switch attaching screws and remove the gauge pin.
8. Connect the switch wires to the plug connector.
9. Check the operation of the switch in each selector lever position. The starter should engage in only the neutral and park detent positions.

ECONOLINE AND BRONCO

1. Remove the downshift linkage rod return spring at the low-reverse servo cover.
2. Apply penetrating oil to the outer lever attaching nut to prevent breaking the inner lever shaft. Remove the transmission downshift outer lever attaching nut and lever.
3. Remove the two neutral start switch retaining bolts (Fig. 7).
4. Disconnect the two multiple wire connectors.
5. Remove the neutral start switch from the transmission.
6. Install the neutral start switch on the transmission. Install the two retaining bolts.
7. With the transmission manual lever in neutral, check the location of the switch with the gauge pin. Install

gauge pin (No. 43 drill) into the gauge pin holes (Fig. 7).
8. Torque the switch attaching bolts to specification and remove the gauge pin.
9. Install the outer downshift lever and retaining nut, and torque the nut to specification. Install the downshift linkage rod return spring between the lever and retaining clip on the low-reverse servo cover.
10. Connect the wire multiple connectors. The red connector has to be inserted into the red connector and the blue connector inserted into the blue connector. Check the operation of the switch in each detent position. The engine should start only with the transmission selector lever in N (neutral) and P (park).

P-350-400-500

1. Place the selector lever in neutral.
2. Disconnect the neutral start switch wires at the switch.
3. Remove the two neutral start switch-to-mounting bracket attaching screws and remove the switch.
4. Position the neutral start switch to the mounting bracket and loosely install the two attaching screws.
5. Move the switch lever to the neutral detent position (Fig. 8) and tighten the attaching screws to 35-50 in-lbs torque.
6. Connect the wires to the neutral start switch.
7. Check the operation of the switch in each selector lever position. The engine should start only with the transmission selector lever in neutral or park.

B-600-700 AND F-600

1. Disconnect the neutral start switch wires at the plug connector.
2. Remove the neutral start switch-to-mounting bracket attaching screws (Fig. 9).
3. Remove the cotter pin securing the neutral start switch to the selector lever arm and remove the switch.
4. Position the neutral start switch to the selector lever arm clevis pin and secure with the flat washer and cotter pin.
5. Install the neutral switch-to-mounting bracket attaching screws.
6. Connect the switch wires to the plug connector.
7. Position the switch so that the starter circuit is closed when the selector lever is in N and then, tighten the switch attaching screws.
8. Check the operation of the switch. The engine should start only with the selector lever in neutral.

DESCRIPTION

Figure 1 shows the location of the converter, front pump, clutches, gear train and most of the internal parts used in the C4 automatic transmission. The identification tag (Fig. 2) is located under the lower front intermediate servo cover bolt. The tag shows the model prefix and suffix, assembly part numbers, and the built date code. The first line on the tag shows the transmission model prefix and suffix. A number appearing after the suffix (Fig. 2) indicates that the internal parts in the transmission have been changed after initial production start-up. For example, a PEA-F model transmission that has been changed internally would read PEA-F1. Both transmissions are basically the same, but some service parts in the PEA-F1 transmission are slightly different than the PEA-F transmission. Therefore, it is important that the codes on the transmission identification tag be checked when ordering parts or making inquiries about the transmission.

The C4 automatic transmission is a three speed unit capable of providing automatic upshifts and downshifts through the three forward gear ratios, and also capable of providing manual selection of first and second gears.

The transmission consists

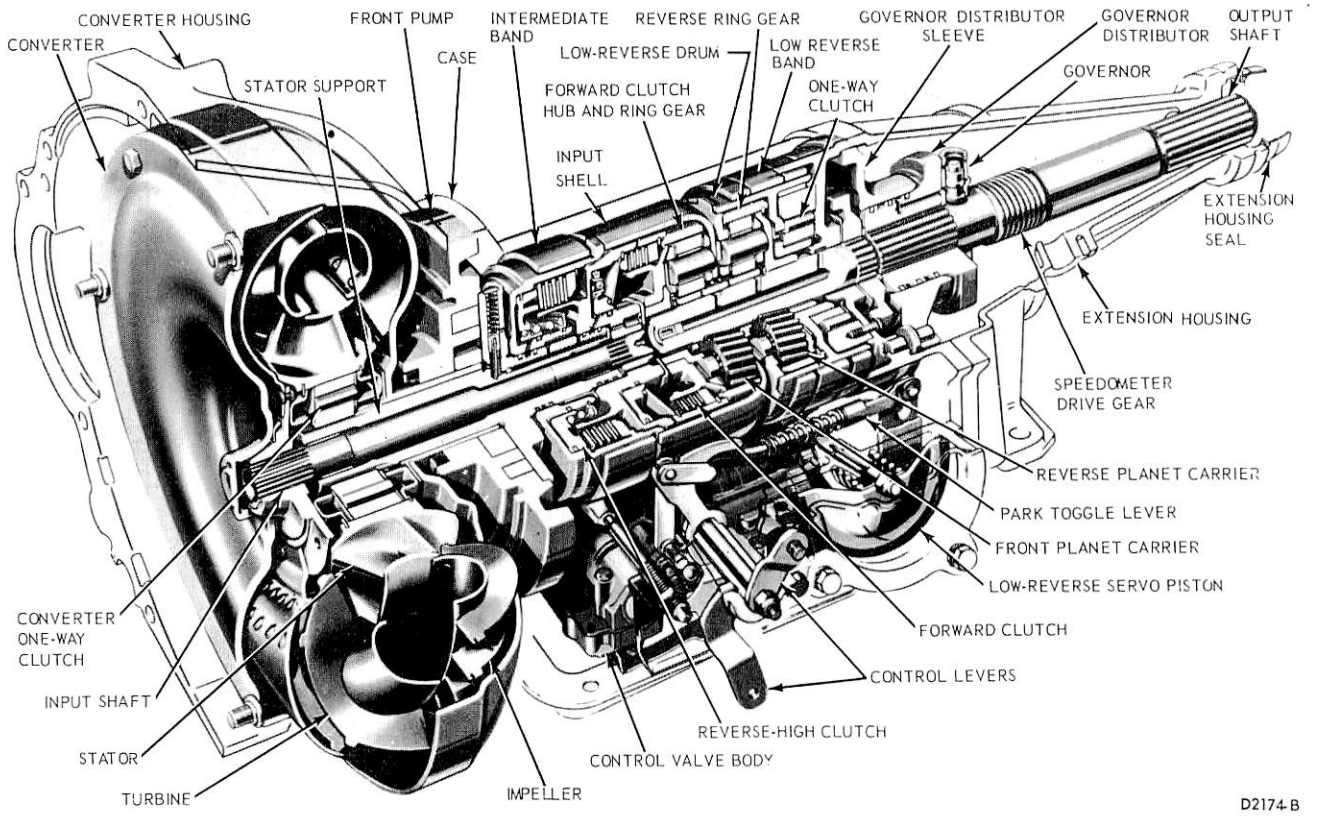

FIG. 1 C4 Automatic Transmission

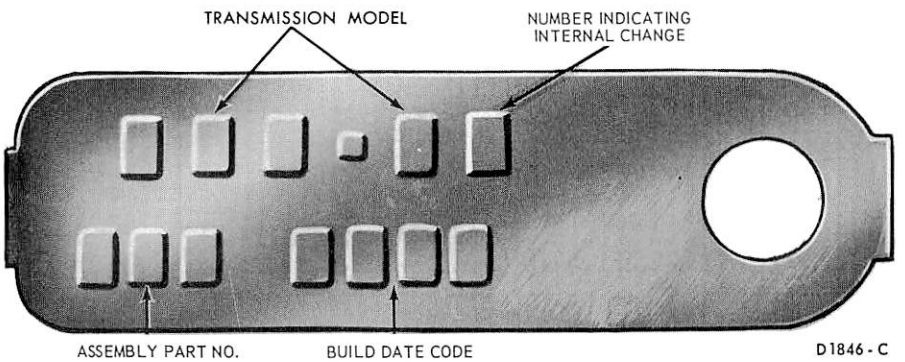

FIG. 2 Identification Tag

essentially of a torque converter, planetary gear train, two multiple disc clutches, a one-way clutch and a hydraulic control system (Fig. 3).

The only adjustments on the transmission are the intermediate and low-reverse bands.

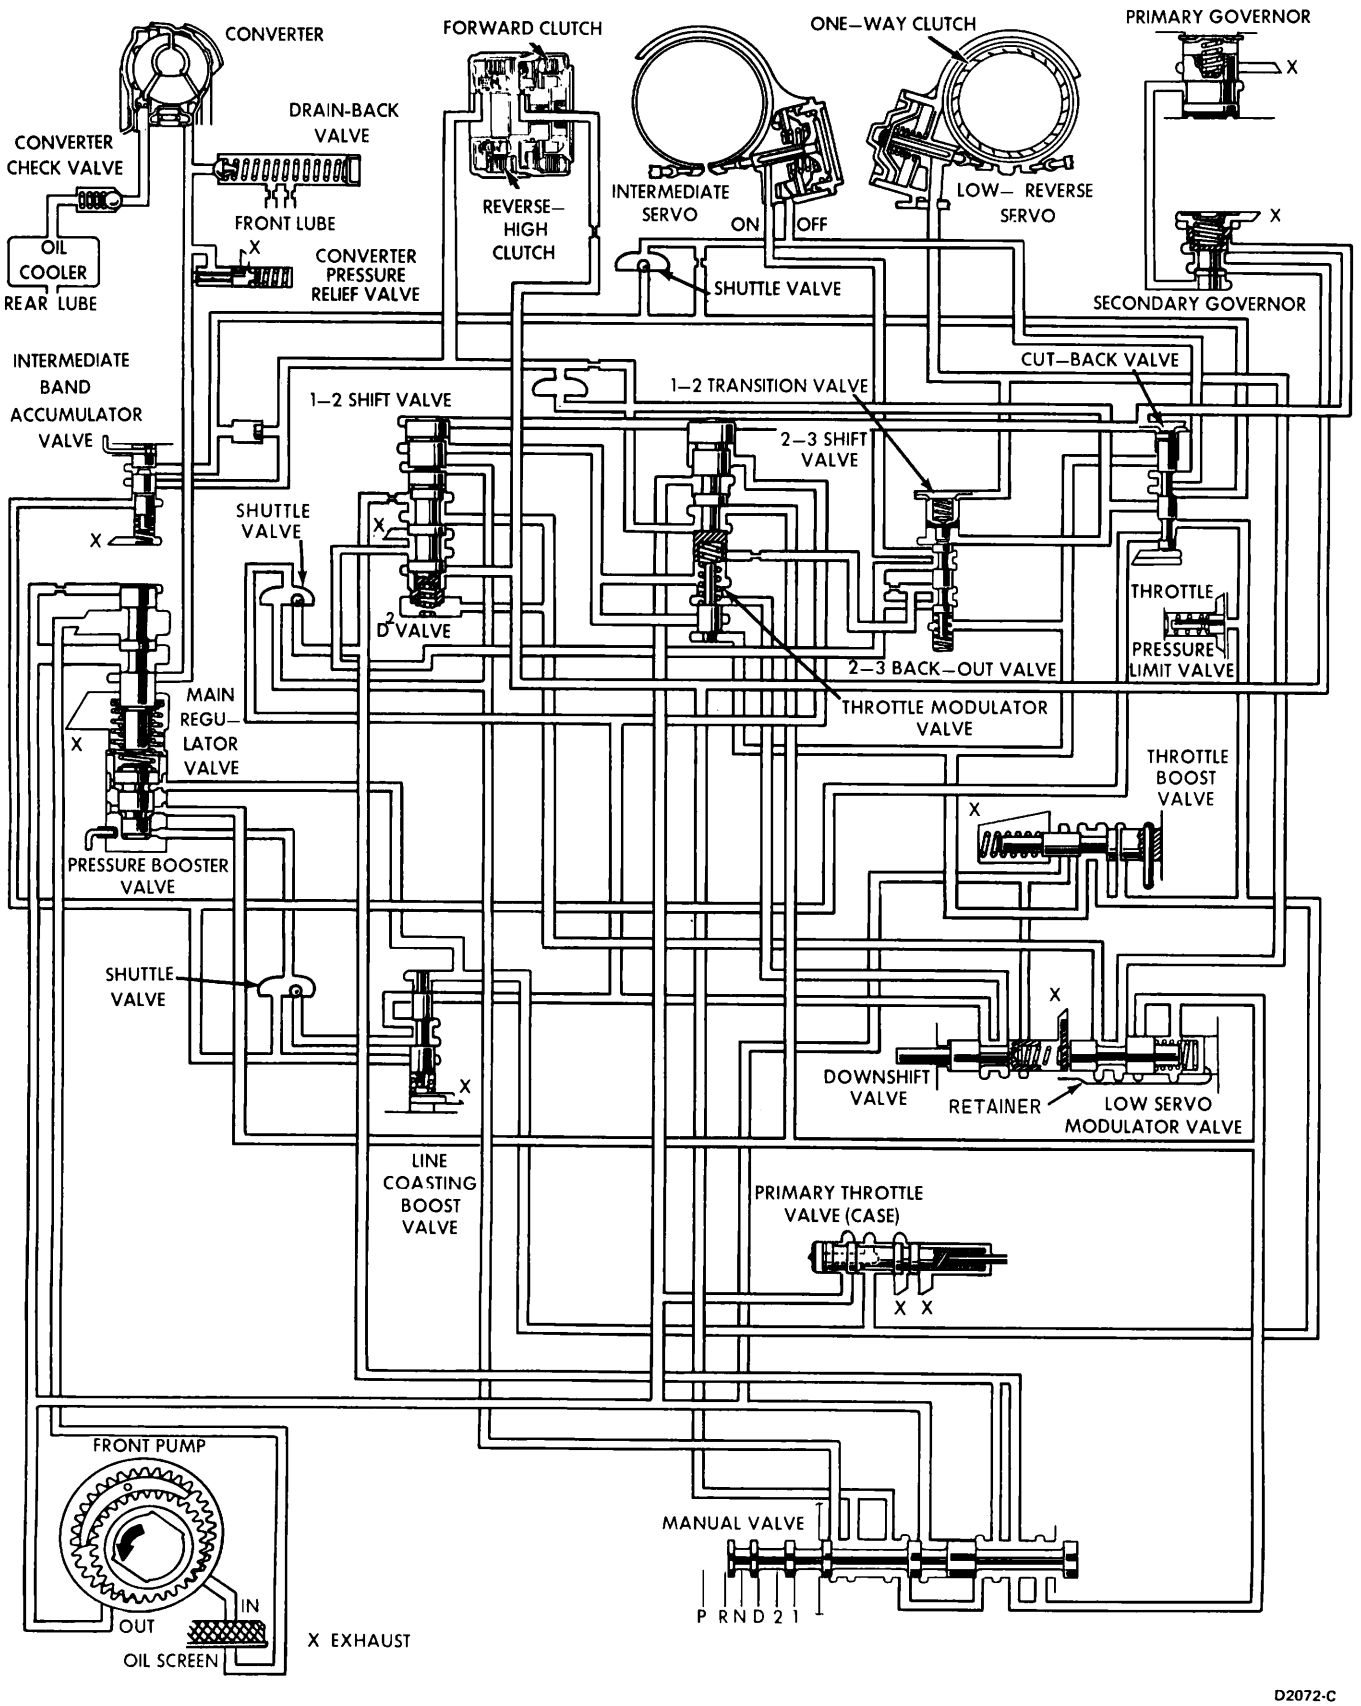

FIG. 3 Hydraulic Control System

ADJUSTMENTS

To prevent damage to the transmission and to assure proper band adjustment, it is essential that the tools and procedures described below are used whenever the bands are adjusted.

INTERMEDIATE BAND ADJUSTMENT

1. Clean all the dirt from the band adjusting screw area. Remove and discard the locknut.
2. Install a new locknut on the adjusting screw. With the tool shown in Fig. 4, tighten the adjusting screw until the tool handle clicks. The tool is a pre-set torque wrench which clicks and breaks when the torque on the adjusting screw reaches 10 ft-lbs.
3. **Back off the adjusting screw exactly 1 3/4 turns.**
4. Hold the adjusting screw from turning and torque the locknut to specification.

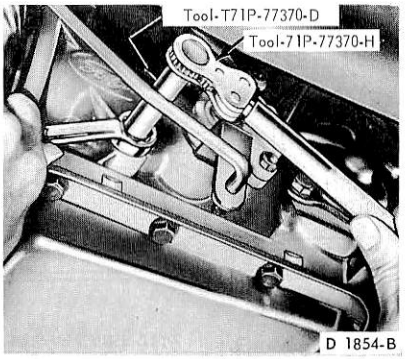

FIG. 4 Adjusting Intermediate Band

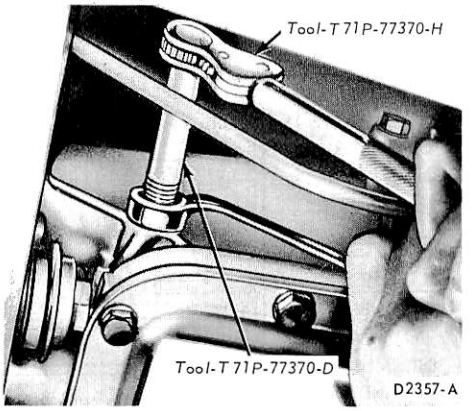

FIG. 5 Adjusting Low-Reverse Band

LOW-REVERSE BAND ADJUSTMENT

1. Clean all the dirt from the band adjusting screw area. Remove and discard the locknut.
2. Install a new locknut on the adjusting screw with the tools shown in Fig. 5 and tighten the adjusting screw until the tool handle clicks. The tool is a pre-set torque wrench which clicks and breaks when the torque on the adjusting screw reaches 10 ft-lbs.
3. **Back off the adjusting screw exactly 3 full turns.**
4. Hold the adjusting screw from turning and torque the locknut to specification.

REMOVAL AND INSTALLATION

TRANSMISSION

F-100-250

Removal

1. Raise the vehicle on a hoist.
2. Place the drain pan under the transmission fluid pan. Remove the fluid filler tube from the pan and drain the transmission fluid.
3. Remove the converter drain plug access cover from the lower end of the converter housing.
4. Remove the converter-to-flywheel attaching nuts. Place a wrench on the crankshaft pulley attaching bolt to turn the converter to gain access to the nuts.
5. With the wrench on the crankshaft pulley attaching bolt, turn the converter to gain access to the converter drain plug. Then, remove the plug (Fig. 6). Place a drain pan under the converter to catch the fluid. After the fluid has been drained from the converter, reinstall the plug.

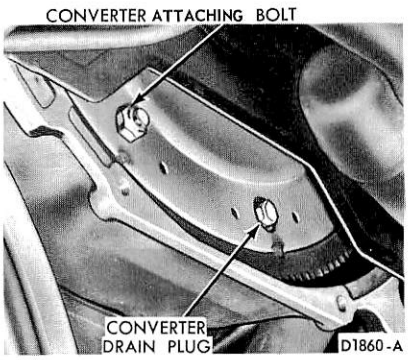

FIG. 6 Converter Drain Plug Location—Typical

6. Remove the drive shaft.
7. Disconnect the oil cooler lines from the transmission.
8. Disconnect the manual and downshift linkage rods from the transmission control levers.
9. Remove the speedometer gear from the extension housing.
10. Disconnect the starter cable. Remove the three starter to converter housing attaching bolts. Remove the starter.
11. Remove the vacuum line hoses from the transmission vacuum unit. Disconnect the vacuum lines from the retaining clip. Disconnect the transmission regulated spark (T.R.S.) switch wire (Fig. 7) at the transmission, if so equipped.
12. Position the transmission jack to support the transmission. Install the safety chain to hold the transmission on the jack.
13. Remove the two engine rear support crossmember-to-frame attaching bolts.
14. Remove the two engine rear support-to-extension housing attaching bolts.
15. Raise the transmission and remove the rear support. Remove the six converter housing-to-engine attaching bolts.
16. Move the transmission away from the engine. Lower the transmission

and remove it from under the vehicle.

Installation

1. Torque the converter drain plug to specification.
2. Position the converter to the transmission making sure the converter drive flats are fully engaged in the pump gear.
3. With the converter properly installed, place the transmission on the jack. Secure the transmission to the jack with the safety chain.
4. Rotate the converter so that the studs and drain plug are in alignment with their holes in the flywheel.
5. With the transmission mounted on the transmission jack, move the converter and transmission assembly forward into position, using care not to damage the flywheel and the converter pilot. **The converter must rest squarely against the flywheel. This indicates that the converter pilot is not binding in the engine crankshaft.**
6. Install the six converter housing-to-engine attaching bolts. Torque the bolts to specification.

Install the converter-to-flywheel attaching nuts. Torque the nuts to specification. Remove the safety chain from the transmission.

7. Install the rear support. Install the rear support-to-extension housing attaching bolts. Torque the bolts to specification.
8. Position the starter into the converter housing and install the three attaching bolts. Torque the bolts to specification. Install the starter cable.
9. Remove the transmission jack.
10. Connect the transmission filler tube to the transmission pan. Connect the oil cooler lines to the transmission.
11. Install the speedometer driven gear in the extension housing. Torque the attaching bolt to specification.
12. Connect the transmission linkage rods to the transmission control levers.
13. Install the drive shaft.
14. Install the vacuum lines in the retaining clip. Connect the vacuum lines to the diaphragm unit. Connect the transmission regulated spark (T.R.S.) switch wire (Fig. 7) to the switch, if so equipped.
15. At the front lower area of the converter housing, install the lower cover and the control lever dust shield. Install the attaching bolts. Torque the bolts to specification.

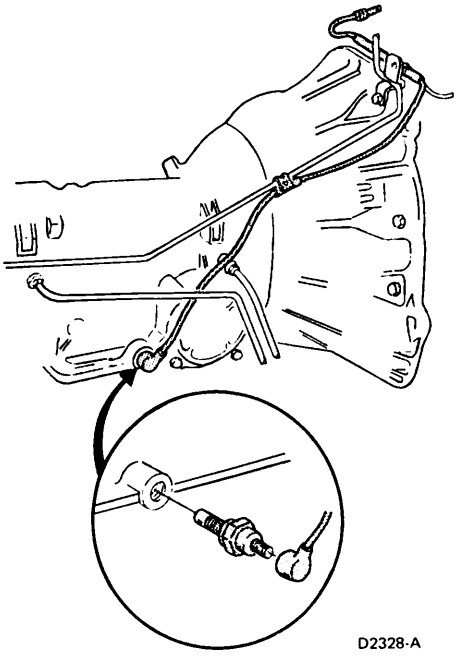

FIG. 7 Transmission Regulated Spark Switch Location

16. Secure the fluid filler tube to the pan. Tighten the fitting to specification.
17. Lower the vehicle.
18. Fill the transmission to the proper level with the specified fluid.
19. Raise the vehicle and check for transmission fluid leakage. Lower the vehicle and adjust the throttle and manual linkage.

ECONOLINE

Removal

1. Working from inside the vehicle, remove the engine compartment cover.
2. Disconnect the neutral start switch wires at the plug connector.
3. If the vehicle is equipped with a V8 engine, remove the flex hose from the air cleaner heat tube.
4. Remove the upper converter housing-to-engine attaching bolts (three bolts on 6-cylinder engines; four bolts on 8-cylinder engines).
5. On V8 engines, remove the upper muffler inlet pipe-to-exhaust manifold flange nut (right side of engine).
6. Raise the vehicle on a hoist.
7. On V8 engines, remove the three remaining muffler inlet pipe-to-exhaust manifold flange nuts and allow the exhaust pipe to hang.
8. Place the drain pan under the transmission fluid pan. Remove the fluid filler tube from the pan and drain the transmission fluid.
9. Remove the converter drain plug access cover from the lower end of the converter housing.
10. Remove the converter-to-flywheel attaching nuts. Place a wrench on the crankshaft pulley attaching bolt to turn the converter to gain access to the nuts.
11. With the wrench on the crankshaft pulley attaching bolt, turn the converter to gain access to the converter drain plug. Then, remove the plug (Fig. 6). Place a drain pan under the converter to catch the fluid. After the fluid has been drained from the converter, reinstall the plug.
12. Disconnect the drive shaft.
13. Remove the bolt retaining the fluid filler tube to the engine and remove the tube.
14. Disconnect the starter cable at the starter. Remove the starter-to-converter housing attaching bolts and remove the starter.
15. Position the engine support bar (Tool T65E-6000-J) to the side rail and engine oil pan flanges.
16. Disconnect the cooler lines from the transmission. Disconnect the vacuum lines from the vacuum diaphragm unit. Disconnect the transmission regulated spark (T.R.S.) switch wire (Fig. 7) at the transmission, if so equipped.
17. Remove the speedometer driven gear from the extension housing.
18. Disconnect the manual and downshift linkage rods from the transmission control levers.
19. Position a transmission jack to support the transmission. Install the safety chain to hold the transmission on the jack.
20. Remove the bolt and nut securing the rear mount to the crossmember. Remove the four bolts retaining the crossmember to the side rails. Then, with the transmission jack, raise the transmission and remove the crossmember.
21. Remove the remaining converter housing-to-engine attaching bolts. Lower the transmission and remove it from under the vehicle.

Installation

1. Torque the converter drain plug to specification.
2. Position the converter to the transmission making sure the converter drive flats are fully engaged in the pump gear.
3. With the converter properly

installed, place the transmission on the jack. Secure the transmission to the jack with the safety chain.
4. Rotate the converter so that the studs and drain plug are in alignment with their holes in the flywheel.
5. With the transmission mounted on the transmission jack, move the converter and transmission assembly forward into position, using care not to damage the flywheel and the converter pilot. **The converter must rest squarely against the flywheel. This indicates that the converter pilot is not binding in the engine crankshaft.**
6. Install the lower converter housing-to-engine attaching bolts. Torque the bolts to specification. Install the converter-to-flywheel attaching nuts. Torque the nuts to specification.
7. Install the crossmember. Install the rear mount-to-crossmember attaching bolt and nut. Torque the bolts to specifications.
8. Remove the safety chain and remove the jack from under the vehicle. Remove the engine support bar.
9. Connect the cooler lines to the transmission. Connect the vacuum lines to the vacuum diaphragm unit. Connect the transmission regulated spark (T.R.S.) switch wire (Fig. 7) to the switch, if so equipped.
10. Install the speedometer driven gear into the extension housing. Torque the attaching bolt to specification.
11. Connect the transmission linkage rods to the transmission control levers.
12. Connect the transmission filler tube to the transmission pan. Secure the tube to the engine with the attaching bolt.
13. Install the converter housing cover and torque the attaching bolts to specification.
14. Position the starter into the converter housing and install the attaching bolts. Torque the bolts to specification. Install the starter cable.
15. Install the drive shaft.
16. If equipped with a V8 engine, install the muffler inlet pipe on the exhaust manifolds and install and torque the three retaining nuts.
17. Lower the vehicle.
18. On V8 engines, install and torque the upper muffler inlet pipe-to-exhaust manifold flange nut.
19. Install the upper converter housing-to-engine attaching bolts. Torque the bolts to specification.
20. On V8 engines, install the flex hose to the air cleaner heat tube.
21. Connect the neutral start switch wires at the plug connector.
22. Fill the transmission to the proper level with the specified fluid.
23. Raise the vehicle and check for transmission fluid leakage. Lower the vehicle and adjust the throttle and manual linkage.
24. Install the engine compartment cover.

BRONCO

Removal
1. Working from the engine compartment, remove the four screws retaining the fan shroud to the radiator.
2. Raise the vehicle on a hoist.
3. Remove the transfer case shield if so equipped.
4. Place a drain pan under the transmission fluid pan. Remove the fluid filler tube from the pan and drain the transmission fluid.
5. Drain the transfer case.
6. Remove the converter drain plug access cover from the lower end of the converter housing.
7. Remove the converter-to-flywheel attaching nuts. Place a wrench on the crankshaft pulley attaching bolt to turn the converter to gain access to the nuts.
8. With the wrench on the crankshaft pulley attaching bolt, turn the converter to gain access to the converter drain plug. Then, remove the plug. Place a drain pan under the converter to catch the fluid. After the fluid has been drained from the converter, reinstall the plug.
9. Disconnect the rear drive shaft at the transfer case and position it out of the way.
10. Disconnect both ends of the front driveshaft and remove it from the vehicle.
11. Disconnect the complete exhaust system and position it out of the way.
12. Remove the speedometer gear from the transfer case.
13. Disconnect the oil cooler lines from the transmission.
14. Disconnect the manual and downshift linkage rods from the transmission control levers.
15. Disconnect the neutral start switch wires from the retaining clamps and connectors.
16. Disconnect the starter cable. Remove the three starter-to-converter housing attaching bolts. Remove the starter.
17. Remove the vacuum hoses from the transmission vacuum unit. Disconnect the vacuum lines from the retaining clip.
18. Remove the bolts, washers, plates and insulators that secure the crossmember to the transfer case adapter.
19. Remove the crossmember-to-frame side support attaching bolts.
20. Position a transmission jack to support the transmission and transfer case.
21. Raise the transmission and transfer case assembly and remove the four bolts securing the left side support bracket to the frame. Remove the side support bracket, crossmember and upper crossmember insulators from the vehicle.
22. Raise the transmission and transfer case slightly and disconnect the shift rod from the transfer case shift lever bracket.
23. Remove the bolts that attach the shift lever bracket to the transfer case adapter and allow the assembly to hang by the shift lever.
24. Secure the transmission and transfer case assembly to a transmission jack and remove the six converter housing-to-engine attaching bolts.
25. Move the transmission and transfer case away from the engine. Lower the assembly and remove it from under the vehicle.
26. Move the assembly to a bench and remove the transfer case adapter-to-transmission attaching bolts.
27. Slide the transmission off the transfer case.

Installation
1. Position the transfer case to the transmission and install the attaching bolts. Torque the bolts to specification.
2. Torque the converter drain plug to specification.
3. Position the converter to the transmission making sure the converter drive flats are fully engaged in the pump gear.
4. With the converter properly installed, position the transmission and transfer case assembly on a transmission jack and secure the assembly in place.
5. Rotate the converter so that the studs and drain plug are in alignment with their holes in the flywheel.
6. With the transmission and transfer case mounted on a transmission jack, move the assembly forward into position, using care not to damage the flywheel and the converter pilot. **The converter must rest squarely against the flywheel. This indicates that the converter pilot is not binding in the engine crankshaft.**
7. Install the six converter housing-to-

engine attaching bolts. Torque the bolts to specification.
8. Position the shift lever bracket to the transfer case adapter and install the attaching bolts.
9. Connect the shift rod to the shift lever bracket and secure with the spring washer, flat washer and cotter pin.
10. Raise the transmission and transfer case high enough to provide clearance for installing the crossmember. Position the left side support bracket to the frame and install the four attaching bolts. Place the upper insulators to the crossmember and install the crossmember. Install the crossmember-to-frame side support attaching bolts.
11. Align the bolt holes in the transfer case adapter with those in the crossmember, then lower the transmission and remove the jack.
12. Install the crossmember-to-transfer case adapter bolts, insulators, plates and washers.
13. Install the flywheel-to-converter attaching nuts. Torque the nuts to specification.
14. Position the starter in the converter housing and install the three attaching bolts. Torque the bolts to specification. Install the starter cable.
15. Connect the transmission filler tube to the transmission pan. Connect the oil cooler lines to the transmission.
16. Install the vacuum lines in the retaining clip. Connect the vacuum hoses to the vacuum unit.
17. Install the speedometer gear in the transfer case.
18. Connect the neutral start switch wires to their respective connectors and secure the harness in the retaining clamps.
19. Connect the transmission linkage rods to the transmission control levers.
20. Install the exhaust system.
21. Install the rear axle driveshaft to the transfer case and torque the attaching bolts to specification.
22. Position the front driveshaft to the front axle and transfer case and install attaching bolts. Torque the bolts to specification.
23. Install the converter drain plug access cover and secure it with the attaching bolts.
24. Fill the transfer case to the proper level with the recommended lubricant.
25. Install the transfer case shield if so equipped.
26. Lower the vehicle.

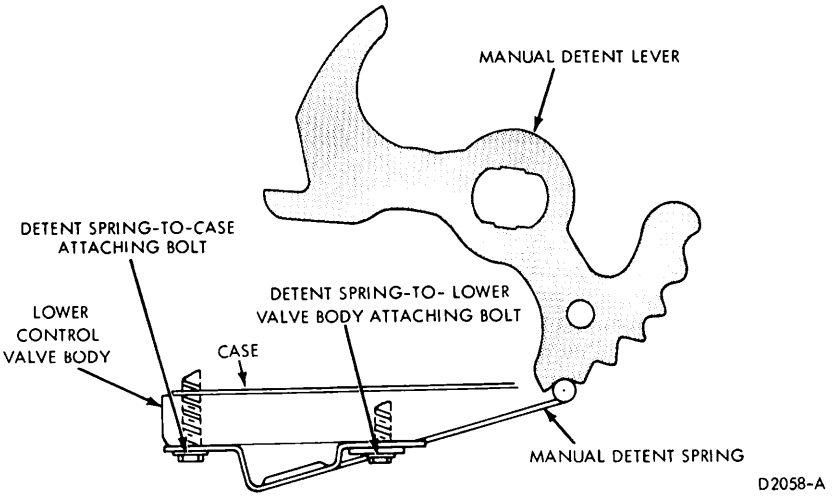

FIG. 8 Control Valve Body Detent Spring Installed

27. Position the fan shroud to the radiator and secure with the four retaining screws.
28. Fill the transmission to the proper level with the specified fluid. Adjust the manual and downshift linkage as required.

CONTROL VALVE BODY

1. Raise the vehicle so the transmission oil pan is accessible.
2. Disconnect the fluid filler tube from the pan and allow the fluid to drain into a container.

If the same fluid is to be used again, filter the fluid through a 100 mesh screen. Reuse the fluid only if it is in good condition.

3. Remove the transmission fluid pan attaching bolts, pan and gasket.
4. Shift the transmission manual lever to the P position and remove the two bolts that attach the detent spring to the valve body and case (Fig. 8).
5. Remove the remaining valve body-to-case attaching bolts. Hold the manual valve to keep it from sliding out of the valve body and remove the valve body from the case. Failure to hold the manual valve while removing the control assembly, could cause the manual valve to become bent or damaged.
6. Refer to Disassembly and Assembly in this Part for the control valve body repair operations.
7. Thoroughly clean and remove all gasket material from the pan and pan mounting face of the case. Remove and discard the nylon shipping plug from the oil pan filler tube hole. This plug is used to retain transmission fluid within the transmission during shipment and should be discarded when the oil pan is removed.
8. Shift the manual lever at the transmission into the P detent position. Install the valve body to the case. Position the inner downshift lever between the downshift lever stop and the downshift valve. Make sure the two lands on the end of the manual valve engage the actuating pin on the manual detent lever. Install seven valve body-to-case bolts. Do not tighten the bolts at this time.
9. Position the detent spring to the lower valve body and install the spring-to-case bolt finger tight (Fig. 8).
10. Hold the detent spring roller in the center of the manual detent lever and install the detent spring-to-lower valve body bolt (Fig. 8). Tighten the bolt to 80-120 in-lbs torque.
11. Tighten all the control valve body-to-case attaching bolts to 80-120 in-lbs torque.
12. Place a new gasket on the pan. Install the pan and attaching bolts. Torque the bolts to specification.
13. Connect the filler tube to the pan and tighten the fitting securely.
14. Lower the vehicle and fill the transmission with fluid. Check the transmission pan area for fluid leakage.

INTERMEDIATE SERVO

1. Raise the vehicle and remove the transmission forward cooler line. Remove the four servo cover-to-case attaching bolts. Remove the identification tag.
2. Remove the vacuum lines at the

transmission. Remove the servo cover, gasket, piston, and piston return spring. Remove the piston from the cover (Fig. 53).
3. Remove the piston seals and cover gasket.
4. Install new piston seals on the piston. Lubricate the piston seals with clean transmission fluid. Install the servo piston in the cover.
5. Install the piston return spring in the case. Place a new gasket on the cover. Install the piston and cover into the transmission case.
6. Use two 5/16-18 x 1 1/4 bolts, 180 degrees apart to position the cover against the case.
7. Install the transmission identification tag. Install the two servo cover attaching bolts. Remove the two 1 1/4 inch bolts and install two attaching bolts. Torque the bolts to specification.
8. Install the vacuum and oil cooler lines.
9. Adjust the intermediate band. Lower the vehicle and check the transmission fluid level.
10. If the band can not be adjusted properly, the struts are not in position. Remove the pan and valve body. Install the struts, valve body, pan, and adjust the band. Refill the transmission with fluid.

LOW-REVERSE SERVO

1. Raise the vehicle on a hoist.
2. Loosen the reverse band adjusting screw locknut. Tighten the reverse band adjusting screw to 10 ft-lbs torque. (Tightening the screw will insure that the band strut will be held against the case by the band, preventing it from falling down when the reverse servo piston assembly is removed).
3. Remove the four servo cover-to-case attaching bolts. Remove the vent tube retaining clip. Remove the servo cover and seal from the case.
4. Remove the servo piston from the case (Fig. 55).**The piston seal cannot be replaced, without replacing the piston. The seal is bonded to the piston.**
5. Install the piston into the case. Install a new seal on the cover. Install the cover by using two 5/16-18 bolts, 1 1/4 inch long, at 180 degrees apart to position the servo cover on the case. Install the vent tube retaining clip. Install two cover attaching bolts. Remove the two installing bolts and install the last two attaching bolts. Torque the cover-to-case attaching bolts to specification.

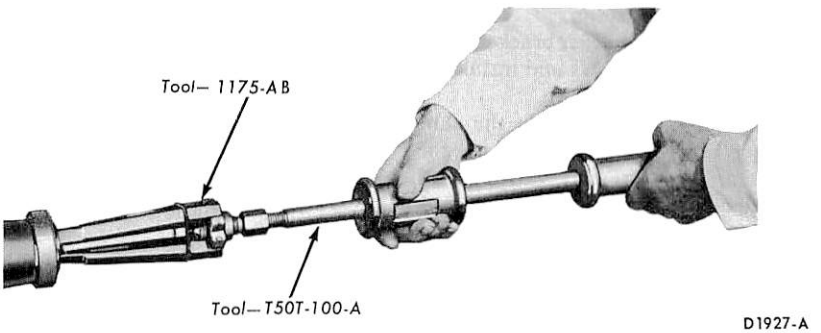

FIG. 9 Removing Extension Housing Seal—F-100-250 and Econoline

6. Adjust the low-reverse band. Lower the vehicle and check the transmission fluid level.
7. If the band can not be adjusted properly, the struts are not in position. Remove the fluid pan and valve body. Install the struts, valve body, pan, and adjust the band. Refill the transmission with fluid.

EXTENSION HOUSING BUSHING AND REAR SEAL

F-100-250 AND ECONOLINE

1. Raise the vehicle and disconnect the drive shaft from the transmission.
2. When only the rear seal needs replacing, carefully remove it with a tapered chisel or the tools shown in Fig. 9. Remove the bushing as shown in Fig. 10.**Use the bushing remover carefully so that the spline seal is not damaged.**
3. When installing a new bushing use the special tool shown in Fig. 11.
4. Before installing a new seal, inspect the sealing surface of the universal joint yoke for scores. If scores are found, replace the yoke.
5. Inspect the counterbore of the housing for burrs and remove with crocus cloth.
6. Install the seal into the housing with the tool shown in Fig. 12. The seal should be firmly seated in the bore. Coat the inside diameter of the fiber portion of the seal with C1AZ-19590-B lubricant.
7. Coat the front universal joint spline with C1AZ-19590-B lubricant and install the drive shaft.

EXTENSION HOUSING

F-100-250 AND ECONOLINE

1. Raise the vehicle on the hoist.
2. Remove the drive shaft. Position the transmission jack to support the transmission.

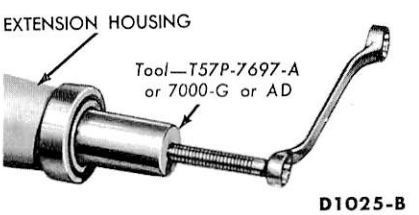

FIG. 10 Removing Extension Housing Bushing—F-100-250 and Econoline

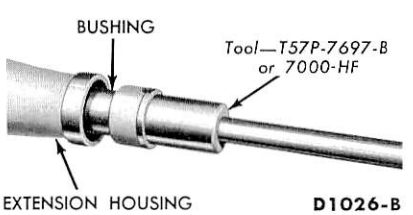

FIG. 11 Installing Extension Housing Bushing—F-100-250 and Econoline

3. Remove the speedometer cable from the extension housing.
4. Remove the crossmember-to-extension housing bolts.
5. Lower the transmission until the extension housing mount clears the body area.
6. Loosen the extension housing attaching bolts to drain the transmission fluid.
7. Remove the six extension housing-to-case attaching bolts and remove the extension housing and gasket.
8. Install a new extension housing gasket on the case. Install the extension housing and six attaching bolts. Torque the bolts to specification.
9. Raise the transmission and install the extension housing-to-crossmember mounting bolts. Torque the bolts to specifications. Remove the transmission jack.
10. Install the speedometer cable in the extension housing. Install the drive shaft.

11. Lower the vehicle and fill the transmission with fluid.
12. Check the extension housing area for fluid leakage.

GOVERNOR

F-100-250 AND ECONOLINE

1. Remove the extension housing as outlined in this section of the manual.
2. Remove the governor housing to governor distributor attaching bolts (Fig. 13). Remove the governor housing from the distributor.
3. Refer to Disassembly and Assembly in this Part for governor repair operations.
4. Install the governor housing on the governor distributor (Fig. 13). Install the attaching bolts and torque the bolts to specification.
5. Reinstall the extension housing.

BRONCO

Removal

1. Working from the engine compartment, remove the four screws retaining the fan shroud to the radiator.
2. Raise the vehicle on a hoist.
3. Remove the transfer case shield if so equipped.
4. Place a drain pan under the transfer case. Remove the drain plug from the transfer case and drain the lubricant.
5. Disconnect the front and rear driveshaft at the transfer case and position them out of the way.
6. Remove the speedometer gear from the transfer case.
7. Disconnect the shift rod from the transfer case shift lever bracket.
8. Remove the bolts, washers, plates and insulators that secure the crossmember to the transfer case adapter.
9. Remove the crossmember-to-frame side support attaching bolts.
10. Position a transmission jack to support the transmission and transfer case.
11. Raise the transmission and transfer case assembly and remove the four bolts securing the left side support bracket to the frame. Remove the side support bracket, crossmember and upper crossmember insulators from the vehicle.
12. Remove the bolts that attach the shift lever bracket to the transfer case adapter and allow the assembly to hang by the shift lever.

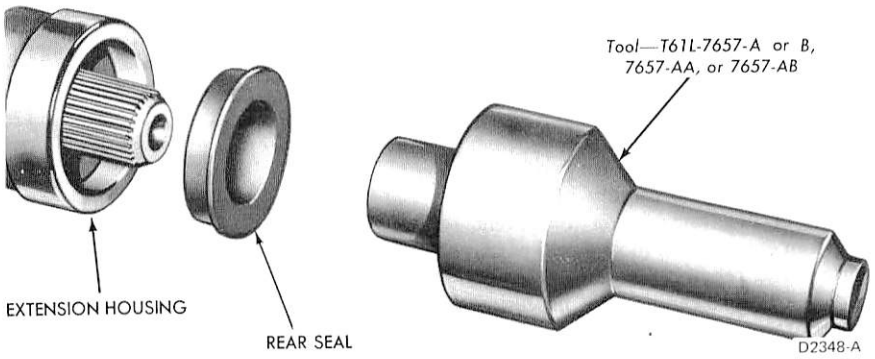

FIG. 12 Installing Extension Housing Seal—F-100-250 and Econoline

13. Secure the transfer case to a transmission jack and remove the six transmission-to-transfer case attaching bolts.
14. Move the transfer case and jack rearward until it clears the transmission output shaft. Lower the transfer case and remove it from under the vehicle.
15. Remove the governor housing-to-governor distributor attaching bolts (Fig. 13). Remove the governor housing from the distributor.
16. Refer to Disassembly and Assembly in this Part for governor repair operations.

Installation

1. Install the governor housing on the governor distributor (Fig. 13). Install and torque the attaching bolts to specification.
2. Clean the mounting surfaces on the transmission and transfer case. Position a new gasket on the transmission.
3. Position the transfer case to the transmission and install the attaching bolts. Torque the bolts to specification.
4. Position the shift lever bracket to the transfer case adapter and install the attaching bolts.
5. Raise the transmission and transfer case high enough to provide clearance for installing the crossmember. Position the left side support bracket to the frame and install the four attaching bolts. Place the upper insulators to the crossmember and install the crossmember. Install the crossmember-to-frame side support attaching bolts.
6. Align the bolt holes in the transfer case adapter with those in the crossmember, then lower the transmission and remove the jack.

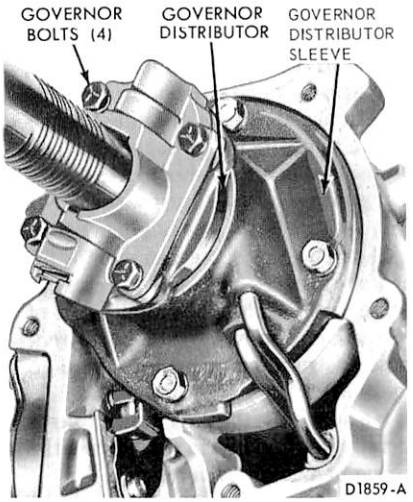

FIG. 13 Governor Installed

7. Install the crossmember-to-transfer case adapter bolts, insulators, plates and washers.
8. Connect the shift rod to the shift lever bracket and secure with the spring washer, flat washer, and cotter pin.
9. Install the speedometer gear in the transfer case.
10. Install the front and rear driveshafts to the transfer case.
11. Fill the transfer case to the proper level with the recommended lubricant.
12. Install the transfer case shield if so equipped.
13. Lower the vehicle.
14. Position the fan shroud to the radiator and secure with the four retaining screws.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Before removing any of the subassemblies, thoroughly clean the outside of the transmission to prevent dirt from entering the mechanical parts. During the repair operation, refer to Part 17-01 for cleaning and inspection procedures.

During the transmission disassembly or assembly operations, ten thrust washers located between the subassemblies must be removed and installed. It is important that each thrust washer be in the correct position during the assembly operation. To properly locate and identify the thrust washers, the various positions of the thrust washers are shown in the illustrations and are numbered 1 through 10. No. 1 is at the first thrust washer located at the front pump. The last thrust washer, No. 10, is located at the parking pawl gear.

During the repair of the subassemblies, certain general instructions which apply to all units of the transmission must be followed. These instructions are given here to avoid unnecessary repetition.

Handle all transmission parts carefully to avoid nicking or burring the bearing or mating surfaces.

Lubricate all internal parts of the transmission before assembly with clean automatic transmission fluid. **Do not use any other lubricants except on gaskets and thrust washers which may be coated with vaseline to facilitate assembly.** Always install new gaskets when assembling the transmission.

Tighten all bolts and screws to the recommended torque as outlined in the Specification Section.

Disassembly

1. Remove the converter from the transmission front pump and converter housing.

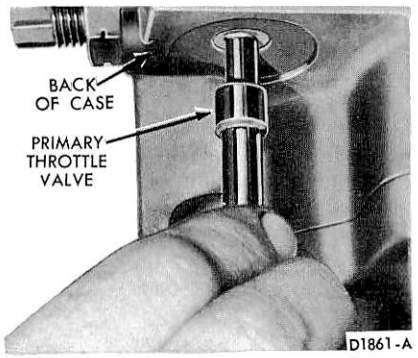

FIG. 14 Removing or Installing Primary Throttle Valve

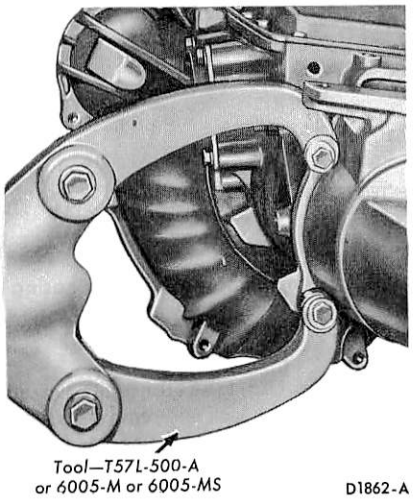

FIG. 15 Transmission Mounted in Holding fixture

2. Remove the transmission vacuum unit.

   Remove the vacuum unit control rod.
3. Remove the primary throttle valve (Fig. 14), from the opening at the rear of the case.
4. Remove the two extension housing-to-case bolts shown in Fig. 15 and mount the transmission in the holding fixture.

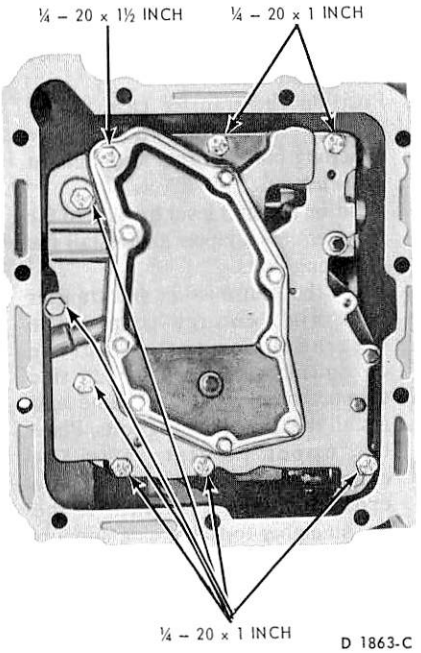

FIG. 16 Control Valve Body-To-Case Attaching bolts—Typical

5. Remove the transmission pan attaching bolts, pan and gasket.
6. Remove the control valve body attaching bolts (Fig. 16). Remove the control valve body from the case.
7. Loosen the intermediate band adjusting screw (Fig. 17) and remove the intermediate band struts from the case. Loosen the low-reverse band adjusting screw and remove the low-reverse band struts.

Transmission End Play Check

1. To keep the output shaft in alignment during the end play check, install the extension housing oil seal replacer tool or a front universal joint yoke in the extension housing.
2. Remove one of the converter housing-to-case attaching bolts and mount the dial indicator as shown in Fig. 18.
3. **The input shaft is a loose part and has to be properly engaged with the spline of the forward clutch hub during the end play checking procedure.** Move the input shaft and gear train toward the rear of the transmission case.
4. With the dial indicator contacting the end of the input shaft, set the indicator at zero (Fig. 18).
5. Insert a screwdriver behind the input shell (Fig. 18). Move the input shell and the front part of the gear train forward.
6. Record the dial indicator reading. The end play should be 0.008 to 0.042 inch. If the end play is not within specification, the selective thrust washers (Fig. 19) must be

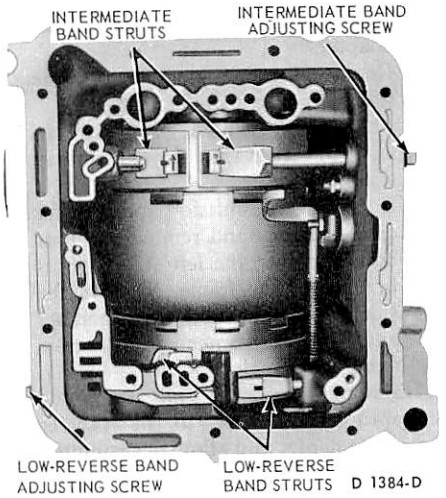

FIG. 17 Band Adjusting Screws and Struts—Typical

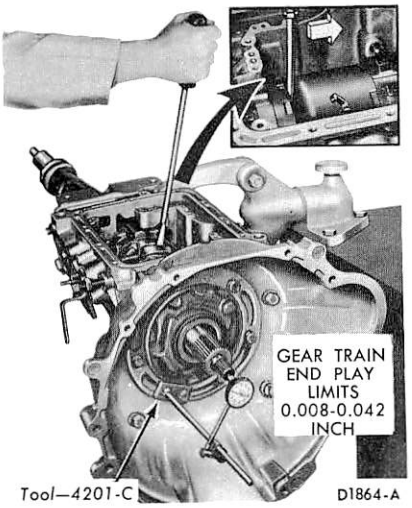

FIG. 18 Checking End Play

SELECTIVE THRUST WASHERS
(FOR END-PLAY CORRECTION)

THRUST WASHER NO. 1		THRUST WASHER NO. 2	
0.053-0.0575	Red	No. Stamped Washer	Metal Thrust Washer
0.070-0.074	Green		
0.087-0.091	Natural	1	0.043-0.041
0.104-0.108	Black	2	0.058-0.056
0.121-0.125	Yellow	3	0.075-0.073
		SPACER (This is a selective spacer used with washer 2 or 3. When used, install next to stator support.)	0.036-0.032

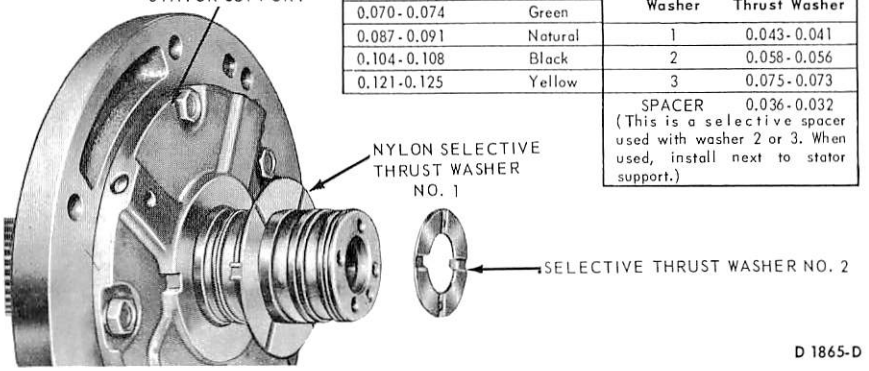

FIG. 19 Selective Thrust Washer Locations

replaced as required. The selective thrust washers can be replaced individually to obtain the specified end play.

7. Remove the dial indicator and remove the input shaft from the front pump stator support (Fig. 20).

Removal of Case and extension Housing Parts

1. Rotate the holding fixture to put the transmission in a vertical position with the converter housing up.
2. Remove the converter housing-to-case attaching bolts (Fig. 20). Remove the converter housing from the transmission case.
3. Remove the seven front pump attaching bolts. Remove the front pump by inserting a screwdriver behind the input shell (Fig. 21). Move the input shell forward until the front pump seal is above the edge of the case.
4. Remove the front pump and gasket from the case. If the selective thrust washer No. 1 did not come out with the front pump, remove it from the top of the reverse-high clutch.
5. Remove the intermediate and low-reverse band adjusting screws from the case. Rotate the intermediate band to align the band ends with the clearance hole in the case (Fig. 22). Remove the intermediate band from the case. **If the intermediate band is to be re-used, it must not be cleaned in a vapor degreaser or with a detergent solution. Wipe it clean with a lint-free cloth.**
6. Using a screwdriver between the input shell and rear planet carrier (Fig. 23), lift the input shell upward and remove the forward part of the gear train as an assembly (Fig. 24).
7. Place the forward part of the gear train in the holding fixture shown in Fig. 25.
8. With the gear train in the holding fixture, remove the reverse-high clutch and drum from the forward clutch (Fig. 26).
9. If thrust washer No. 2 (Fig. 19) did not come out with the front pump, remove the thrust washer from the forward clutch cylinder. If a selective spacer was used, remove the spacer. Remove the forward clutch from the forward clutch hub and ring gear (Fig. 26).
10. If thrust washer No. 3 (Fig. 26) did not come out with the forward clutch, remove the thrust washer from the forward clutch hub.
11. Remove the forward clutch hub and ring gear from the front planet carrier (Fig. 26).
12. Remove thrust washer No. 4 and the front planet carrier from the input shell.
13. Remove the input shell, sun gear and thrust washer No. 5 from the holding fixture.
14. From inside the transmission case (Fig. 24) remove thrust washer No. 6 from the top of the reverse planet carrier.
15. Remove the reverse planet carrier and thrust washer No. 7 from the reverse ring gear and hub (Fig. 27).

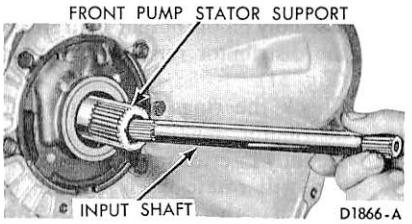

FIG. 20 Removing or Installing Input Shaft

16. Move the output shaft forward and with the tool shown in Fig. 28 remove the reverse ring gear hub-to-output shaft retaining ring.
17. Remove the reverse ring gear and hub from the output shaft. Remove thrust washer No. 8 from the low and reverse drum.
18. Remove the low-reverse band from the case (Fig. 29).
19. Remove the low-reverse drum from the one-way clutch inner race (Fig. 27).
20. Remove the one-way clutch inner race by rotating the race clockwise as it is removed.
21. Remove the 12 one-way clutch rollers, springs and the spring retainer from the outer race (Fig. 26). **Do not lose or damage any of the 12 springs or rollers. The outer race of the one-way clutch cannot be removed from the case until the extension housing, output shaft and governor distributor sleeve are removed.**

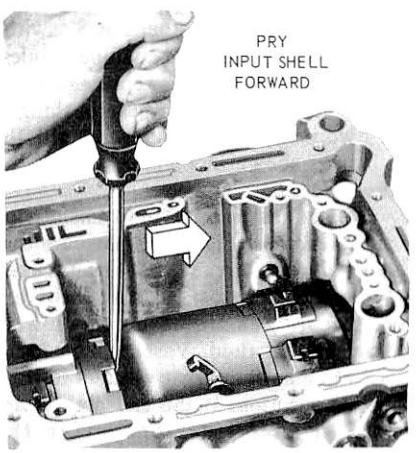

FIG. 21 Removing Front Pump

FIG. 22 Position of Intermediate Band for Removal or Installation

22. Remove the transmission from the holding fixture. Position the transmission on the bench in a vertical position with the extension housing up. Remove the four extension housing-to-case attaching bolts. Remove the extension housing and gasket from the case.
23. Pull outward on the output shaft and remove the output shaft and governor distributor assembly from the governor distributor sleeve (Fig. 30).
24. Remove the governor distributor lock ring from the output shaft (Fig. 31). Remove the governor distributor from the output shaft.
25. Remove the four distributor sleeve-to-case attaching bolts. Remove the distributor sleeve from the case. **Do not bend or distort the oil tubes as the tubes are removed from the case with the distributor sleeve.**
26. Remove the parking pawl return spring, pawl, and pawl retaining pin from the case (Fig. 32).
27. Remove the parking gear and thrust washer No. 10 from the case.
28. Remove the six one-way clutch outer race-to-case attaching bolts with the tool shown in Fig. 33. As the bolts are removed, hold the outer race located inside the case in position. Remove the outer race and thrust washer No. 9 from the case (Fig. 27).
29. Do not remove the T.R.S. switch from the case, if so equipped, unless the switch requires replacement.
30. If the transmission case bushing is worn or damaged, replace it with the tools shown in Figure 34.

Assembly

When assembling the transmission subassemblies (Fig. 35), make sure that the correct thrust washer is used between certain subassemblies. Lubricate remaining surfaces with transmission fluid. Vaseline should be used to hold the thrust washers in their proper location. If the end play is not within specifications after the transmission is assembled, either the wrong selective thrust washers were used, or a thrust washer came out of position during the transmission assembly operation.

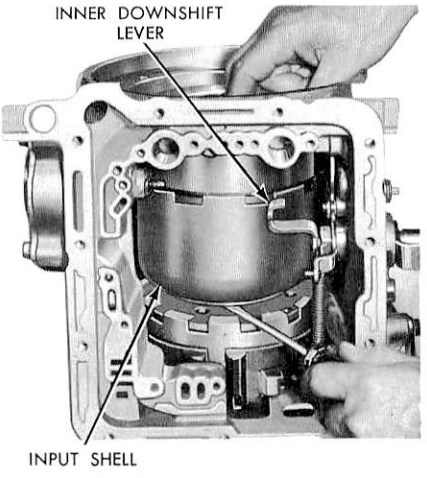

FIG. 23 Lifting Input Shell and Gear Train

1. Install thrust washer No. 9 inside the transmission case (Fig. 36).
2. Place the one-way clutch outer race inside the case. From the back of the case install the six outer race-to-case attaching bolts. Torque the bolts to specification with the tools shown in Fig. 37.
3. Place the transmission case in a vertical position with the back face of the case upward. Install the parking pawl retaining pin in the case (Fig. 38).
4. Install the parking pawl on the case retaining pin. Install the parking pawl return spring as shown in fig. 38.
5. Install thrust washer No. 10 on the parking gear (Fig. 39). Place the gear and thrust washer on the back face of the case (Fig. 38).
6. Place the two distributor tubes in the governor distributor sleeve. Install the distributor sleeve on the case. As the distributor sleeve is installed, the tubes have to be inserted in the two holes in the case and the parking pawl retaining pin has to be inserted in the alignment hole in the distributor sleeve.
7. Install the four governor distributor sleeve-to-case attaching bolts and torque the bolts to specification.
8. Install the governor distributor assembly on the output shaft. Install the distributor retaining snap ring (Fig. 31).
9. Check the rings in the governor distributor, making sure the rings are fully inserted in the ring grooves and will rotate freely. Install the output shaft and governor distributor assembly in the distributor sleeve (Fig. 30).

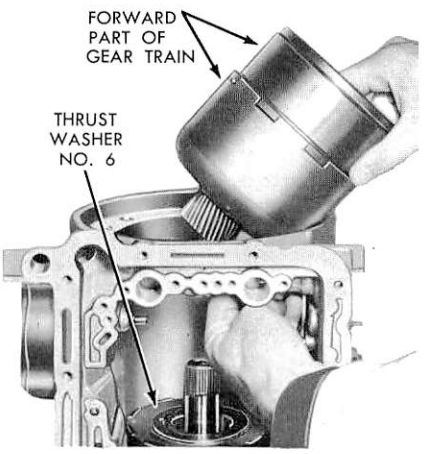

FIG. 24 Removing or Installing Forward Part of Gear Train

10. Place a new extension housing gasket on the case. Install the extension housing and the extension housing-to-case attaching bolts. Torque the bolts to specification.
11. Place the transmission in the holding fixture. Rotate the holding fixture to put the transmission in a vertical position with the front pump mounting face up. **Make sure thrust washer No. 9 is still located at the bottom of the transmission (Fig. 36).**
12. Install the one-way clutch spring retainer into the outer race (Fig. 40).
13. Install the inner race inside of the spring retainer. Be sure the face with the step is installed toward the rear of the case, mating with the thrust washer.
14. Install the individual springs between the inner and outer race as shown in Fig. 40.

FIG. 25 Forward Part of Gear Train Positioned in Holding Fixture

15. Starting at the back of the transmission case, install the one-way clutch rollers by slightly compressing each spring and positioning the roller between the spring and the spring retainer.
16. After the one-way clutch has been assembled, rotate the inner race clockwise to center the rollers and springs. Install the low and reverse drum (Fig. 35). The splines of the drum have to engage with the splines of the one-way clutch inner race. Check the one-way clutch operation by rotating the low and reverse drum. The drum should rotate clockwise but should not rotate counterclockwise.
17. Install thrust washer No. 8 on top of the low and reverse drum (Fig. 41). Install the low-reverse band in the case, with the end of the band for the small strut toward the low-reverse servo (Fig. 29).
18. Install the reverse ring gear and hub on the output shaft.
19. Move the output shaft forward and install the reverse ring gear hub-to-output shaft retaining ring (Fig. 28).
20. Place thrust washers Nos. 6 and 7 on the reverse planet carrier (Fig. 42).
21. Install the planet carrier in the reverse ring gear and engage the tabs of the carrier with the slots in the low-reverse drum.
22. On the bench, install the forward clutch in the reverse-high clutch by rotating the units to mesh the reverse-high clutch plates with the splines of the forward clutch (Fig. 43).
23. Using the end play check reading that was obtained during the transmission disassembly to determine which No. 2 steel backed thrust washer is required, proceed as follows:
    a. Position the stator support vertically on the work bench and install the correct No. 2 thrust washer or washer and spacer as required to bring the end play within specifications.
    b. Install the reverse-high clutch and the forward clutch on the stator support.
    c. Invert the complete unit making sure that the intermediate brake drum bushing is seated on the forward clutch mating surface.
    d. Select the thickest fiber washer (No. 1) that can be inserted between the stator support and the intermediate brake drum thrust surfaces and still maintain a slight clearance. **Do not select a washer that must be forced between the stator support and intermediate brake drum.**
    e. Remove the intermediate brake drum and forward clutch unit from the stator support.
    f. Install the selected Nos. 1 and 2 thrust washers on the front pump stator support (Fig. 19). using enough vaseline to hold the thrust washers in position during the front pump installation.
24. Install thrust washer No. 3 on the forward clutch (Fig. 44).
25. Install the forward clutch hub and ring gear in the forward clutch by rotating the units to mesh the forward clutch plates with the splines on the forward clutch hub (Fig. 45).
26. Install thrust washer No. 4 on the front planet carrier (Fig. 46). Install the front planet carrier into the forward clutch hub and ring gear. **Check the forward thrust bearing race inside the planet carrier for proper location against the thrust bearing. Make sure the race is centered for alignment with the sun gear on the input shell (Fig. 47).**
27. Install the input shell and sun gear on the gear train (Fig. 48). Rotate the input shell to engage the drive lugs of the reverse-high clutch. If the drive lugs will not engage, the outer race inside the forward planet carrier is not centered to engage the end of the sun gear inside the input shell. Center the thrust bearing race and install the input shell.
28. Hold the gear train together and install the forward part of the gear train assembly in the case (Fig. 24). The input shell sun gear must mesh with the reverse pinion gears. The front planet carrier internal splines must mesh with the splines on the output shaft.
29. A new band should be soaked in transmission fluid for fifteen minutes before it is installed. Install the intermediate band through the front of the case (Fig. 22).
30. Install a new front pump gasket on the case. Line up the bolt holes in the gasket with the holes in the case.
31. Install the front pump stator support into the reverse-high clutch. Align the pump-to-case attaching bolt holes. Install the front pump-to-case attaching bolts and torque them to specification.
32. Install the input shaft (Fig. 20). Be sure the short splined end is installed toward the rear of the transmission. Rotate the holding fixture to place the transmission in a horizontal position. Check the transmission end play as shown in Fig. 18. If the

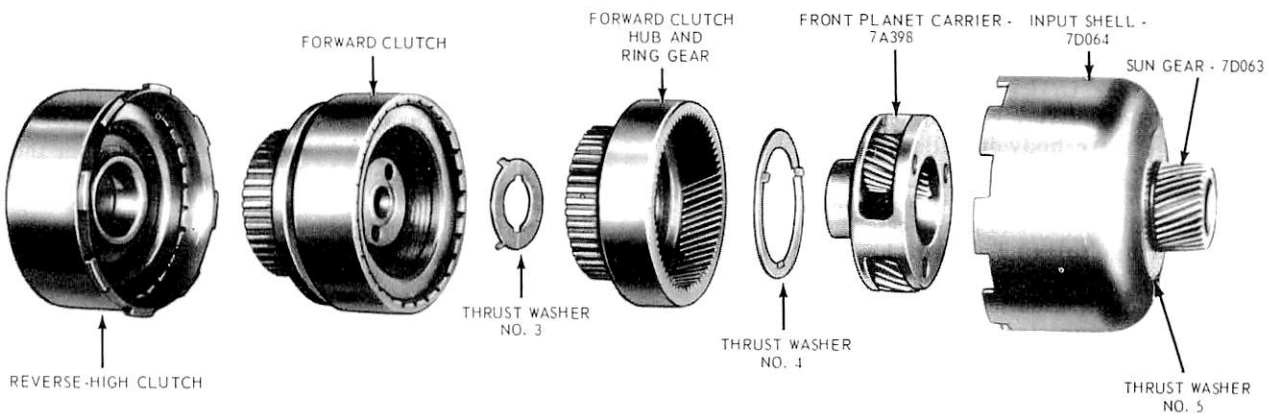

FIG. 26 Forward Part of Gear Train Disassembled

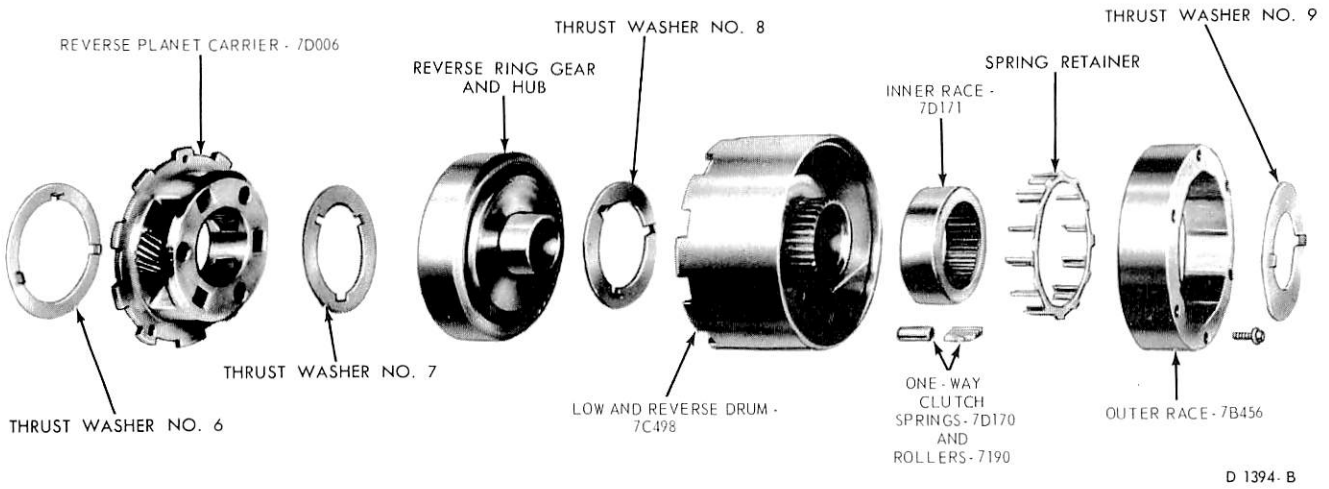

FIG. 27 Lower Part of Gear Train Disassembled

end play is not within specification, either the wrong selective thrust washers (Fig. 19) were used, or one of the 10 thrust washers (Fig. 35) is not properly positioned.

33. Remove the dial indicator used for checking the end play and install the one front pump-to-case attaching bolt. Torque the bolt to specification.
34. Place the converter housing on the transmission case. Install the five converter housing-to-case attaching bolts. Torque the bolts to specification.
35. Install the intermediate and low-reverse band adjusting screws in the case. Install the struts for each band (Fig. 17).
36. Adjust the intermediate and low-reverse band. Refer to Adjustments in this Part for band adjusting procedures.
37. Install a universal joint yoke on the output shaft. Rotate the input and output shafts in both directions to check for free rotation of the gear train.
38. Install the control valve body (Fig. 16). Refer to Removal and Installation of this Part for the control valve body installation procedures.
39. Place a new pan gasket on the case and install the pan and pan-to-case attaching bolts. Torque the attaching bolts to specification.
40. Remove the transmission from the holding fixture. Install the two extension housing-to-case attaching bolts. Torque the bolts to specification.
41. Install the primary throttle valve in the transmission case (Fig. 14).
42. Install the vacuum unit and control rod in the case.
43. **Make sure the input shaft is properly installed in the front pump stator support and gear train.** The short splined end of the shaft should be installed toward the rear of the transmission. Install the converter in the front pump and the converter housing.
44. Install a new T.R.S. switch, if required. Torque the switch to specification.

CONTROL VALVE BODY

Disassembly

When the main control is disassembled and the valve body-to-screen gasket is removed, the gasket should not be cleaned in a degreaser, solvent or any type of detergent solution. To clean the gasket, wipe it off with a lint-free cloth.

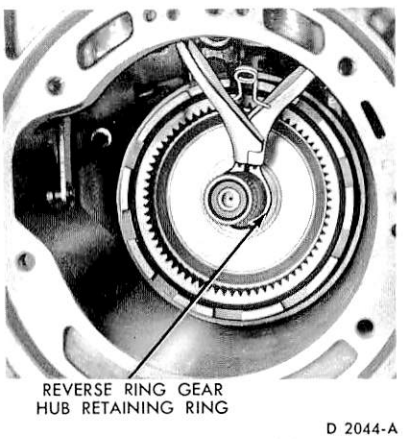

FIG. 28 Removing or Installing Reverse Ring Gear Hub Retaining Ring

1. Remove the eight 10-24 x 1 3/8 inch screws that attach the oil screen to the body (Fig. 49) and remove the screen and gasket (Fig. 50). Be careful not to lose the throttle pressure limit valve and spring when separating the oil screen from the valve body.
2. Remove the two 1/4-20 x 1 1/2 inch attaching screws from the upper valve body and the nine 10 x 24 x 7/8 inch attaching screws from the underside of the lower valve body (Fig. 49). Separate the lower valve body, gasket and separator plate (Fig. 51) from the upper valve body. Be careful not to lose the upper valve body shuttle valve and check valve when separating the upper and lower valve bodies.
3. Remove the manual valve retaining ring and slide the manual valve out of the body. The retaining ring is used to hold the manual valve in its bore during shipment and should be removed and discarded before sliding the manual valve out of the control valve body.
4. Carefully pry the low servo modulator valve retainer from the body and remove the retainer plug, spring and valve from the body. While working in the low servo modulator valve bore, pry the

FIG. 29 Removing or Installing Low-Reverse Band

downshift valve retainer from the body and remove the spring and downshift valve (Fig. 52).
5. Using side cutters, carefully pry the throttle booster valve plug retaining pin from the valve body. Remove the plug, valve and spring.
6. Remove the cut-back valve and transition valve cover plate from the valve body (Fig. 52).
7. Remove the cut-back valve from the body.
8. Remove the transition valve spring, transition valve, 2-3 back-out valve and spring from the body.
9. Remove the 1-2 shift valve and 2-3 shift valve cover plate from the body.
10. Remove the 2-3 shift valve, spring and throttle modulator valve from the body.
11. Remove the 1-2 shift valve, D2 valve and spring from the body.
12. Remove the intermediate servo retaining pin and remove the intermediate accumulator retainer, valve and spring from the body.
13. Press the main oil pressure booster valve inward and remove the retaining pin. Remove the main oil pressure booster valve, sleeve, springs, retainer and the main oil pressure regulator valve.
14. Remove the line coasting boost valve retainer from the body and remove the spring and line coasting boost valve.

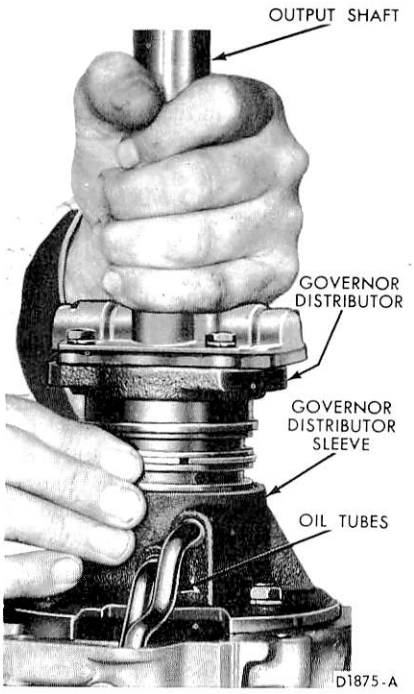

FIG. 30 Removing or Installing Output Shaft and Governor Distributor

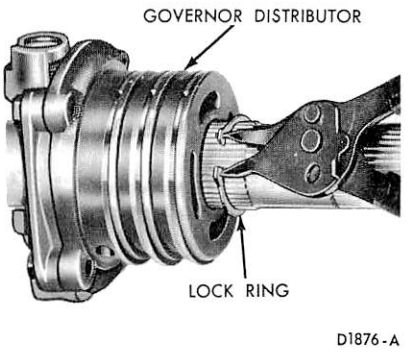

FIG. 31 Removing or Installing Governor Distributor Snap Ring

Assembly
1. Place the shuttle valves in the upper and lower bodies as shown in Figure 51. Position the gasket and separator plate on the lower body and install but do not tighten the attaching screw.
2. Place the lower body and plate assembly on the upper valve body and install the eleven attaching screws finger tight (Fig. 49).
3. Install the oil screen screws loosely, without the screen, to properly align the upper and lower valve bodies, gasket and separator plate.
4. Torque the four bolts that are covered by the screen to specification.
5. Position the throttle pressure limit valve and spring in the lower valve body (Fig. 50). Remove the oil screen attaching screws and place the gasket and oil screen in position on the lower valve body. Reinstall the screen attaching screws (Fig. 49).
6. Torque all the valve body and screen attaching screws to specification.
7. Insert the downshift valve (Fig. 52) into the body with the small diameter facing inward. Install the downshift valve spring and retainer. Insert the low servo modulator valve, spring and retainer plug in the body. Depress the plug and install the retainer.
8. Place the throttle booster valve spring, valve (small diameter end into spring) and plug into the body (Fig. 52). Depress the plug and press in the retaining pin. Be sure the three grooves are at the top of the pin as it is installed.
9. Place the spring, 2-3 back-out valve and the transition valve and spring in the body.
10. Place the cut-back valve in the body.
11. Secure the cut-back and the transition valve cover plate to the body with the two attaching screws. Torque the screws to specification.
12. Place the throttle modulator valve, spring and 2-3 shift valve in the body.
13. Place the spring, D2 valve and the 1-2 shift valve in the body.
14. Secure the 1-2 shift valve and the 2-3 shift valve cover plate to the body with the three attaching screws. Torque the screws to specification.

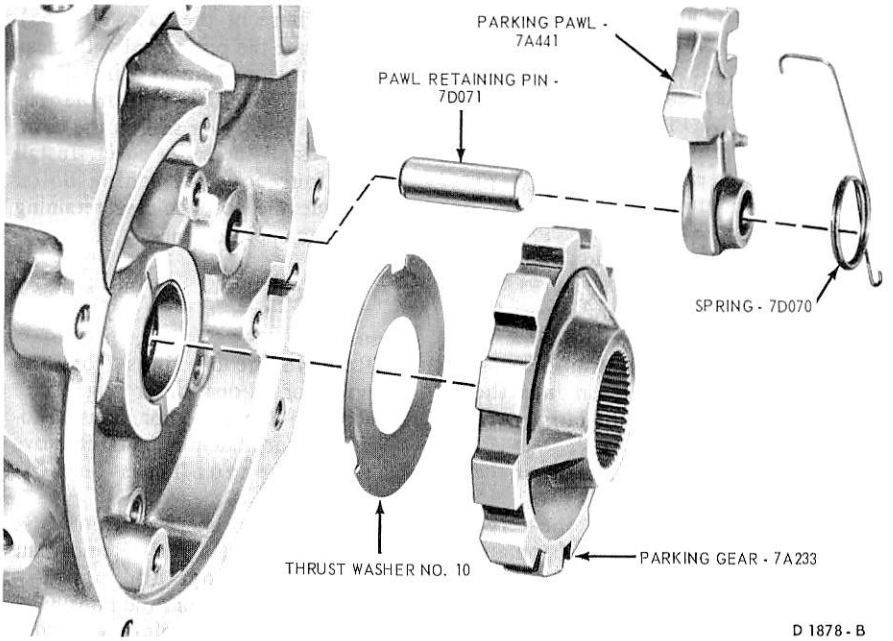

FIG. 32 Parking Pawl, Return Spring Retaining Pin and Gear

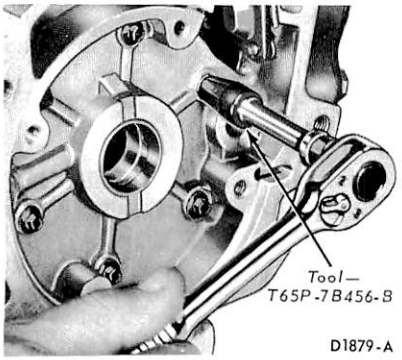

FIG. 33 Removing One-Way Clutch Outer Race Attaching Bolts

15. Place the spring, intermediate servo accumulator valve and retainer in the body. Depress the retainer and install the retaining pin.
16. Insert the line coasting boost valve and spring in the body. Depress the spring and install the retainer.
17. Insert the main oil pressure regulator valve and spring retainer in the body (Fig. 52). Install the two springs, sleeve and the main oil pressure booster valve in the body.
18. Hold the main oil pressure booster valve in place and install the retaining pin.
19. Slide the manual valve into the valve body. Make sure that the end with the two lands closest together is inserted first.

INTERMEDIATE SERVO

Disassembly

1. Remove the transmission identification tag and the four servo cover to case attaching bolts.
2. Remove the servo cover, gasket, servo piston, and piston return spring from the case (Fig. 53).
3. Remove the intermediate servo piston from the cover.
4. Remove the seal rings from the servo piston and cover.

Assembly

1. Install a new seal on the cover and servo piston. Figure 54 shows the correct servo piston and cover for each transmission model. Lubricate the seals with clean transmission fluid. Install the piston into the cover. Be careful not to damage the piston seal.
2. Install the piston return spring in the servo bore of the case.
3. Place a new gasket on the servo cover. Position the servo piston and cover assembly into the case with the piston stem slot in a horizontal position to engage the strut. Use two 5/16-18 bolts, 1 1/4 inch long, 180 degrees apart, to position the cover against the case. Install two cover attaching bolts. Remove the two 1 1/4 inch bolts and install the transmission identification tag and the other two cover attaching bolts. Torque the bolts to specifications.

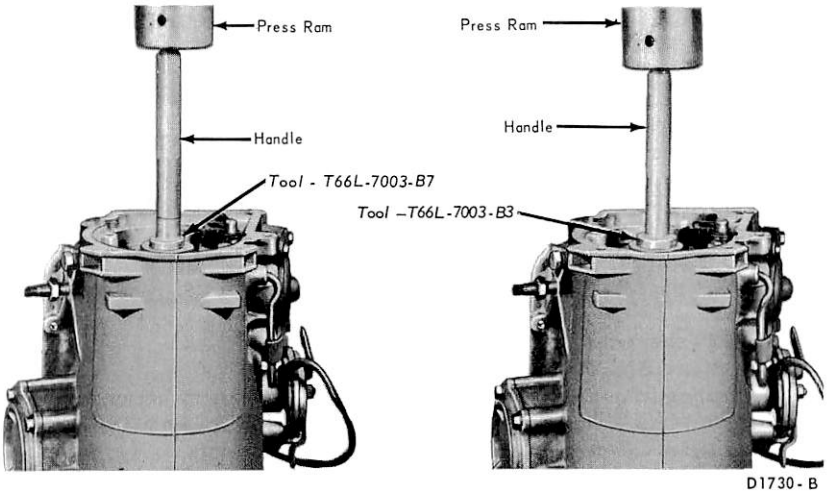

FIG. 34 Replacing Transmission Case Bushing

LOW-REVERSE SERVO

Disassembly

1. Remove the four servo cover-to-case attaching bolts.
2. Remove the servo cover, cover seal, servo piston and piston return spring from the case (Fig. 55).
3. The servo piston seal is bonded to the piston. If the seal has to be replaced, replace the piston assembly which includes the seal.

Assembly

1. Place the piston return spring in the servo bore of the case (Fig. 55). Lubricate the piston seal with clean transmission fluid and install the servo piston into the bore of the case.
2. Place a new cover seal on the cover and install the servo cover. Install the four cover attaching bolts. Torque the cover-to-case retaining bolts to specifications.

GOVERNOR

Disassembly

1. Remove the oil rings from the governor oil distributor (Fig. 56).
2. Remove the governor housing-to-distributor attaching bolts. Remove the governor from the oil distributor.
3. Remove the primary governor valve retaining ring (Fig. 57). Remove the washer, spring, and primary governor valve from the housing.
4. Remove the secondary governor valve spring retaining clip, spring, and governor valve from the housing.

Assembly

1. Install the secondary governor valve in the housing. Install the spring and retaining clip. **Make sure the clip is installed with the small concaved area facing downward, to hold the spring in the correct position.**
2. Install the primary governor valve in the housing. Install the spring, washer and retaining ring. **Make sure the washer is centered in the housing on top of the spring and the retaining ring is fully seated in the ring groove of the housing.**
3. Install the governor assembly on the oil distributor and torque the attaching bolts to specification.
4. Install the oil rings on the distributor. Check the oil rings for free rotation in the ring grooves on the oil distributor.

DOWNSHIFT AND MANUAL LINKAGE

Disassembly

1. Apply penetrating oil to the outer lever attaching nut to prevent breaking the inner lever shaft. Remove the downshift outer lever nut and remove the downshift outer and inner levers.

On vehicles equipped with a case mounted neutral start switch, remove it by placing a screwdriver behind the switch and carefully prying the switch off the lever.

From inside the transmission case, remove the upper retaining ring from the manual lever link (Fig. 58). Remove the upper end of the lever link from the case retaining pin.

2. From the back of the transmission case, remove the upper retaining ring and flat washer from the

FIG. 35 Transmission Subassemblies—Typical

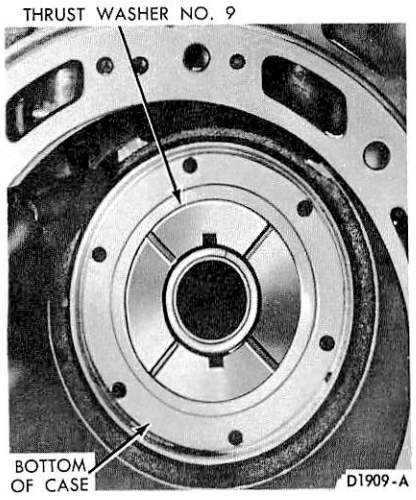

FIG. 36 Number 9 Thrust Washer Location

parking pawl link (Fig. 59). Remove the pawl link from the case retaining pin.

3. From the back of the transmission case, remove the parking pawl link, toggle rod, and manual lever link as an assembly (Fig. 60).
4. Remove the rear parking pawl link lower retaining ring, flat washer and link from the toggle rod (Fig. 58).
5. Remove the manual lever link, lower retaining ring, flat washer, and link from the toggle rod.
6. Install the manual and parking pawl links, flat washers and retaining rings to the toggle rod.
7. Remove the inner manual lever attaching nut and lever. Remove the outer manual lever from the case.
8. To remove the manual lever seal, use the tools shown in Fig. 61. To install the new seal, use the tool shown in Fig. 62.

Assembly

1. Install the outer manual lever in the case. Install the inner manual lever and attaching nut with the chamfer facing toward the lever (Fig. 58). Torque the nut to specification.
2. From the back of the transmission case, install the parking toggle rod and link assembly into the case (Fig. 60).
3. Install the parking pawl link on the case retaining pin. Install the flat washer and link retaining ring (Fig. 59).
4. Position the inner manual lever behind the manual lever link, **with the cam on the lever contacting the lower link pin.**
5. Install the upper end of the manual lever link on the case retaining pin. Install the retaining ring.
6. Operate the manual lever and check for correct linkage operation.
7. On vehicles equipped with a case mounted neutral start switch, reinstall the switch. Adjust the switch after the control valve body has been installed. Torque the attaching bolts to specification.
8. Install the inner and outer downshift levers. Torque the attaching nut to specification.

FRONT PUMP

Disassembly

1. Remove the four seal rings from the stator support.
2. Remove the five bolts that attach the stator support to the front pump housing. Remove the stator support from the pump housing (Fig. 63).
3. Remove the front and rear stator bushings if they are worn or damaged. Use the cape chisel (Fig. 64) and cut along the bushing seam until the chisel breaks through the bushing wall. Pry the loose ends of the bushing up with an awl and remove the bushing.
4. Remove the drive and driven gears from the front pump housing.
5. Press the bushing from the front pump housing as shown in Fig. 65.

Assembly

1. Press a new bushing into the pump housing with the handle and tool shown in Fig. 65. Make sure the bushing is installed with the slot and groove positioned to the rear of the pump body and 60 degrees below the horizontal center line.
2. Install the drive and driven gears in the pump housing. Each gear has an identification mark on the side of the gear teeth that are chamfered. The chamfered side with the identification mark has to be positioned downward against the face of the pump housing.
3. Press new bushings into the stator support with the tool shown in Fig. 66. Use the long end of the tool for the front bushing and the short end for the rear bushing. **When installing the rear bushing, be sure the hole in the bushing is lined up with the lube hole in the stator support.**
4. Place the stator support in the pump housing and install the five attaching bolts. Torque the bolts to specifications.
5. Install the four seal rings on the stator support. The two large oil rings are assembled first in the oil ring grooves toward the front of the stator support (Fig. 63).
6. Check the pump gears for free rotation by placing the pump on the converter drive hub in its normal running position and turning the pump housing.

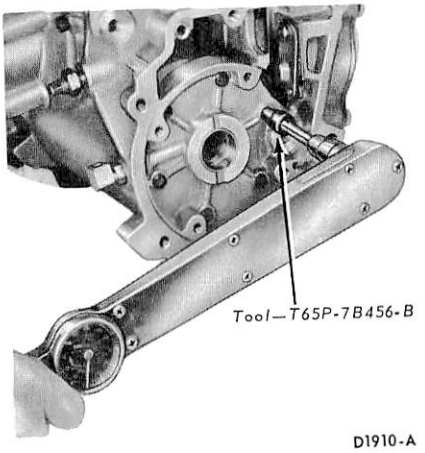

FIG. 37 Installing One-Way Clutch Outer Race Attaching Bolts

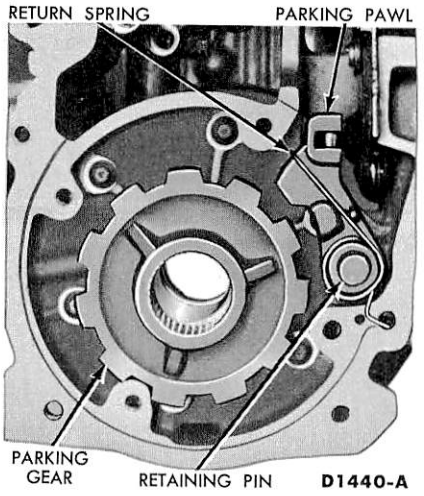

FIG. 38 Parking Pawl and Gear

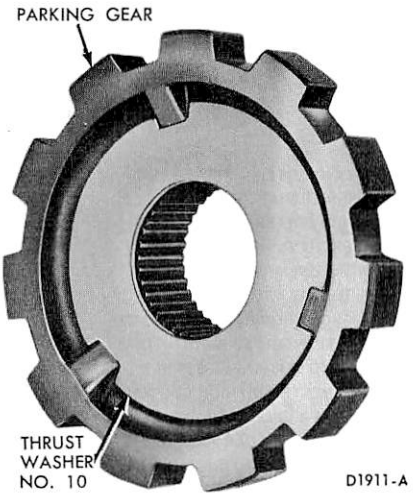

FIG. 39 Number 10 Thrust Washer Location

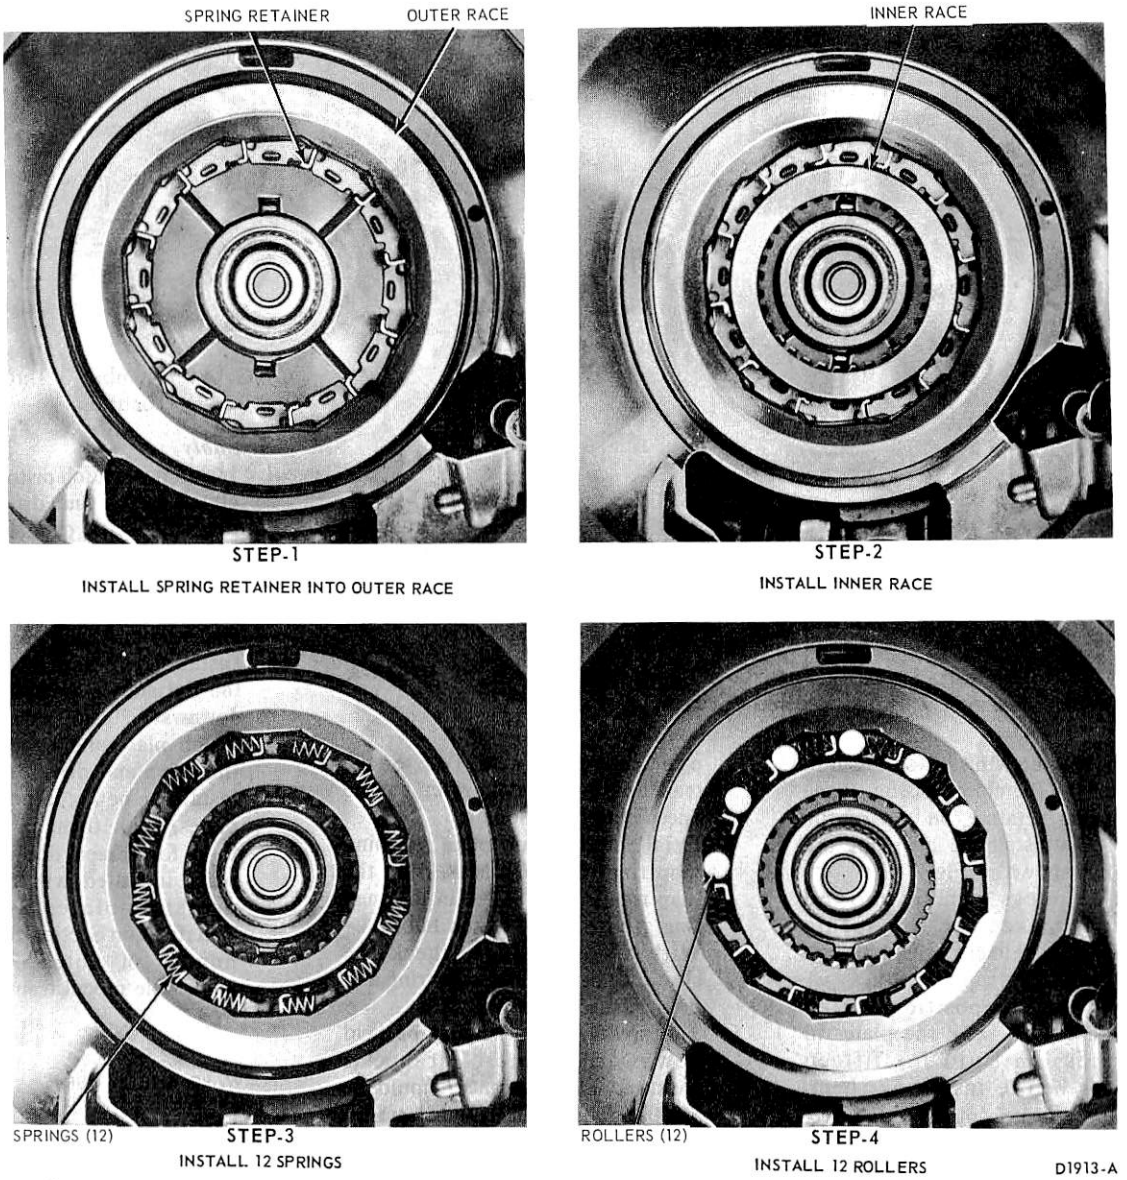

FIG. 40 Installing One-Way clutch

7. If the front pump seal must be replaced, mount the pump in the transmission case and remove the seal with the tool shown in Fig. 67. To install the new seal, use the tool shown in fig. 68.

REVERSE-HIGH CLUTCH

Disassembly

1. Remove the pressure plate retaining snap ring (Fig. 69).
2. Remove the pressure plate, and the drive and driven clutch plates (Fig. 70). **If the composition clutch plates are to be reused, do not clean them in a vapor degreaser or with a detergent solution. Wipe the plates with a lint-free cloth.**
3. To remove the piston spring retainer snap ring, place the clutch hub in the Arbor Press. With the tools shown in Fig. 71, compress the piston return springs and remove the snap ring. When the Arbor Press ram is released, guide the spring retainer to clear the snap ring groove of the drum.
4. Remove the spring retainer and piston return spring.
5. Remove the piston by inserting air pressure in the piston apply hole of the clutch hub (Fig. 72).
6. Remove the piston outer seal from the piston and the piston inner seal from the clutch drum (Fig. 70).

Assembly

1. Install a new inner seal in the clutch drum and a new outer seal on the clutch piston. Lubricate the seals with clean transmission fluid and install the piston into the clutch drum.

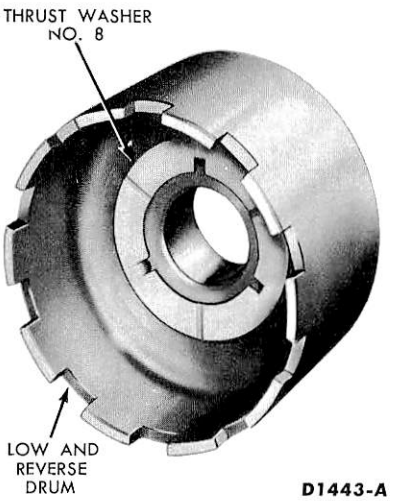

FIG. 41 Number 8 Thrust Washer Location

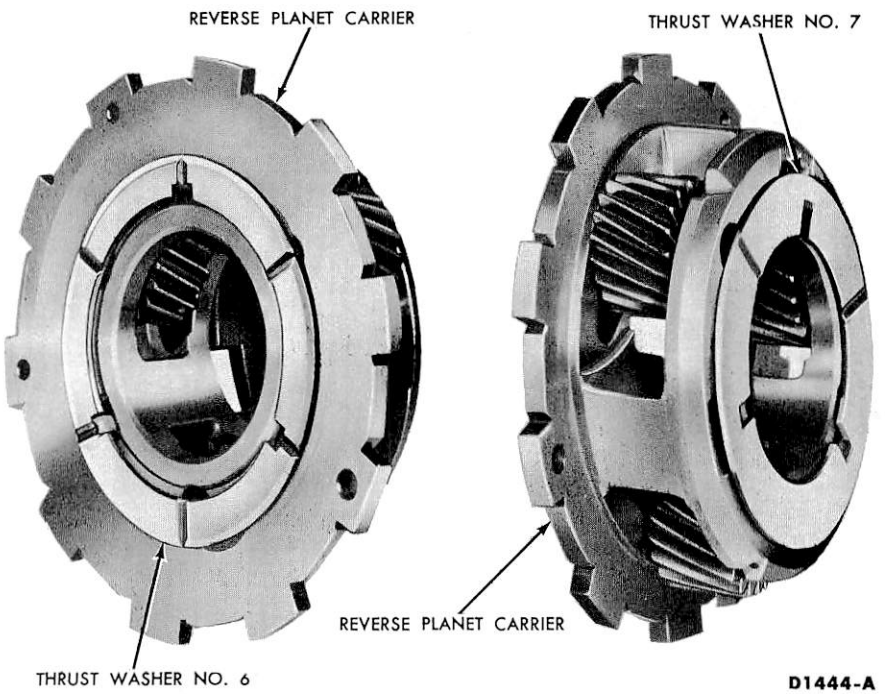

FIG. 42 Number 6 and 7 Thrust Washer Location

2. Place the clutch piston spring into position on the clutch piston. Place the spring retainer on top of the spring. To install the snap ring use the tools shown in Fig. 71.

As the press ram is moved downward, make sure the spring retainer is centered to clear the snap ring groove. Install the snap ring.

3. When new composition clutch plates are used, soak the plates in transmission fluid for fifteen minutes before installing them. Install the clutch plates alternately starting with a steel plate, then a non-metallic plate (Fig. 70). The last plate installed is the pressure plate. For the correct number of clutch plates required for each transmission model, refer to the Specification Section.
4. Install the pressure plate retaining snap ring (Fig. 70). Make sure the snap ring is fully seated in the snap ring groove of the clutch hub.
5. With a feeler gauge, check the clearance between the snap ring and the pressure plate (Fig. 73).
6. The pressure plate should be held downward as the clearance is checked. The clearance should be 0.050 to 0.071 inch. If the clearance is not within specifications, selective thickness snap rings are available in these thicknesses, 0.050-0.054, 0.064-0.068, 0.078-0.082 and 0.092-0.096 inch. Install the correct size snap ring and recheck the clearance.

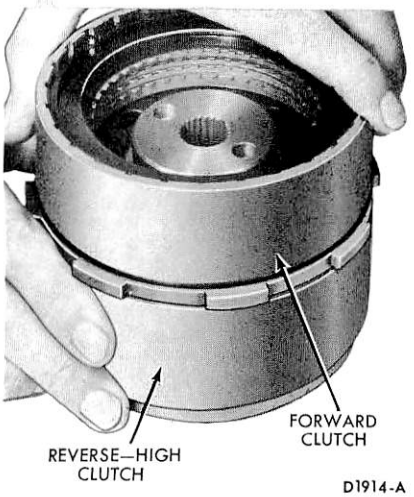

FIG. 43 Installing Clutch Units

FORWARD CLUTCH

Disassembly

1. Remove the clutch pressure plate retaining snap ring (Fig. 74).
2. Remove the pressure plate, and the drive and driven clutch plates from the clutch hub (Fig. 75).
3. Remove the disc spring retaining snap ring (Fig. 76).
4. Apply air pressure at the clutch piston pressure hole (Fig. 77) to remove the piston from the clutch hub.
5. Remove the clutch piston outer seal and the inner seal from the clutch hub (Fig. 75).

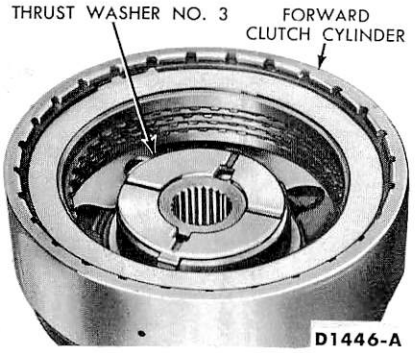

FIG. 44 Number 3 Thrust Washer Location

Assembly

1. Install new clutch piston seals on the clutch piston and drum. Lubricate the seals with clean transmission fluid.
2. Install the clutch piston into the clutch hub. Install the disc spring and retaining snap ring (Fig. 76).
3. **Install the lower pressure plate with the flat side up and the radius side downward.** Install one non-metallic clutch plate and alternately install the drive and driven plates. Before installing new composition clutch plates, soak them in transmission fluid for fifteen minutes. The last plate installed will be the upper pressure plate. Refer to the Specification Section for the correct number of clutch plates for the applicable model transmission.

FIG. 45 Installing Forward Clutch Hub and Ring Gear

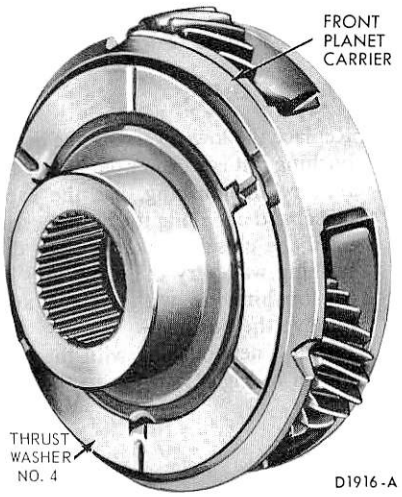

FIG. 46 Number 4 Thrust Washer Location

4. Install the pressure plate retaining snap ring (Fig. 74). Make sure the snap ring is fully seated in the ring groove of the clutch hub.
5. With a feeler gauge, check the clearance between the snap ring and the pressure plate (Fig. 78). Downward pressure on the plate should be used when making this check. The clearance should be 0.025-0.050 inch.
6. If the clearance is not within specifications, selective snap rings are available in these thicknesses: 0.050-0.054, 0.064-0.068, 0.078-0.082 and 0.092-0.096 inch. Insert the correct size snap ring and recheck the clearance.

FORWARD CLUTCH HUB AND RING GEAR

Disassembly

1. Remove the forward clutch hub retaining snap ring (Fig. 79).

FIG. 47 Installing Front Planet Carrier

2. Remove the forward clutch hub from the ring gear.
3. Press the bushing from the clutch hub as shown in Fig. 80.

Assembly

1. Install a new bushing into the clutch hub as shown in Fig. 80.
2. Install the forward clutch hub in the ring gear. Make sure the hub is bottomed in the groove of the ring gear.

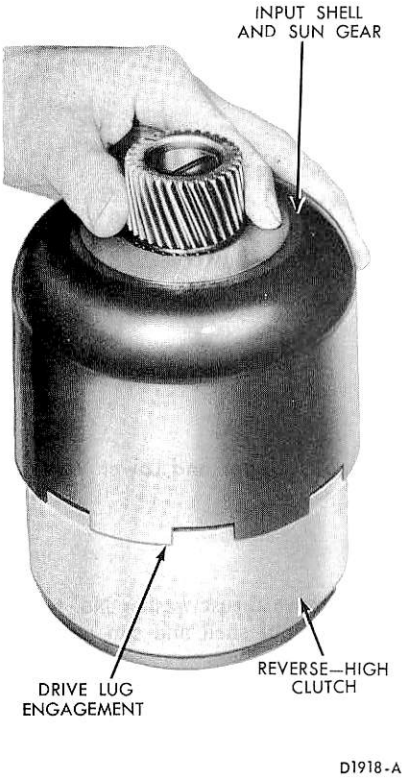

FIG. 48 Installing Input Shell and sun Gear

3. Install the front clutch hub retaining snap ring. Make sure the snap ring is fully seated in the snap ring groove of the ring gear.

INPUT SHELL AND SUN GEAR

Disassembly

1. Remove the external snap ring from the sun gear (Fig. 81).

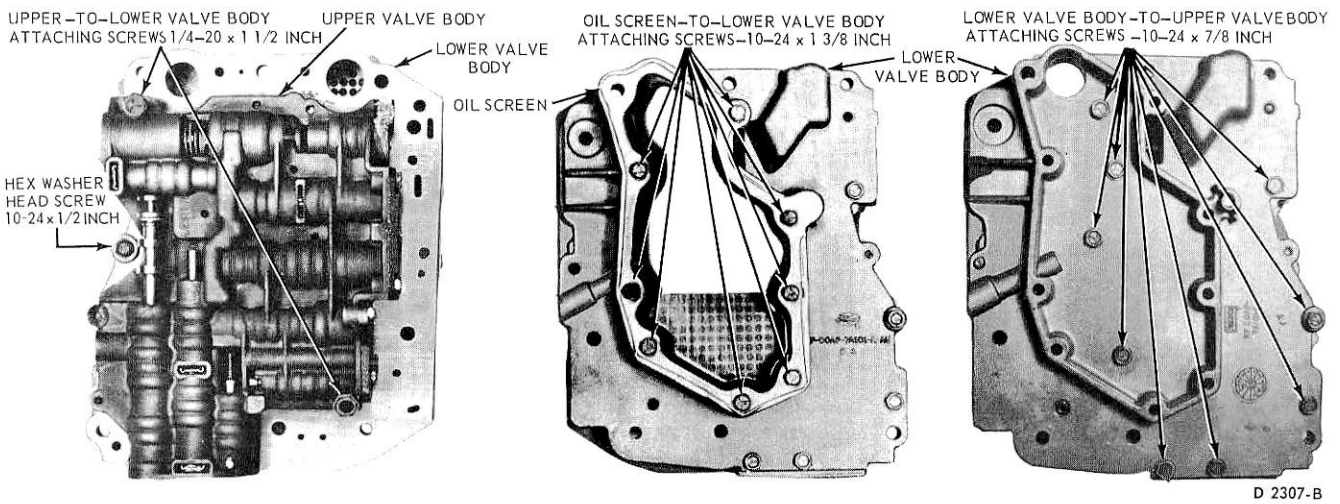

FIG. 49 Control Valve Body and screen Attaching Screws

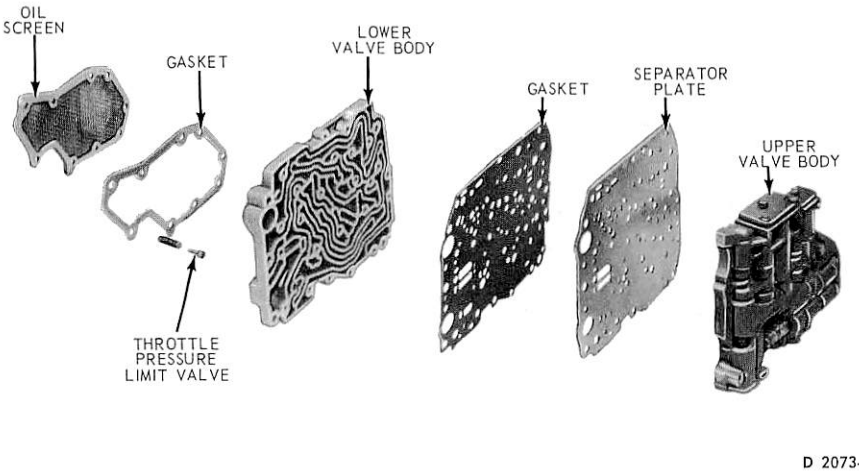

FIG. 50 Upper and Lower Valve Bodies Disassembled

2. Remove thrust washer No. 5 from the input shell and sun gear (Fig. 82).
3. From inside the input shell, remove the sun gear. Remove the internal snap ring from the sun gear.
4. If the sun gear bushings are to be replaced, use the tool shown in Fig. 83 and press both bushings though the gear.

Assembly

1. Press a new bushing into each end of the sun gear with the tool shown in Fig. 83.
2. Install the internal snap ring of the sun gear. Install the sun gear in the input shell.
3. Install thrust washer No. 5 on the sun gear and input shell (Fig. 82).
4. Install the external snap ring on the sun gear (Fig. 81).

REVERSE RING GEAR AND HUB

Disassembly

1. Remove the hub retaining snap ring from the reverse ring gear.
2. Remove the hub from the reverse ring gear (Fig. 84).

Assembly

1. Install the hub in the reverse ring gear. Make sure the hub is fully seated in the groove of the ring gear.
2. Install the snap ring in the reverse ring gear. Make sure the snap ring is fully seated in the snap ring groove of the ring gear.

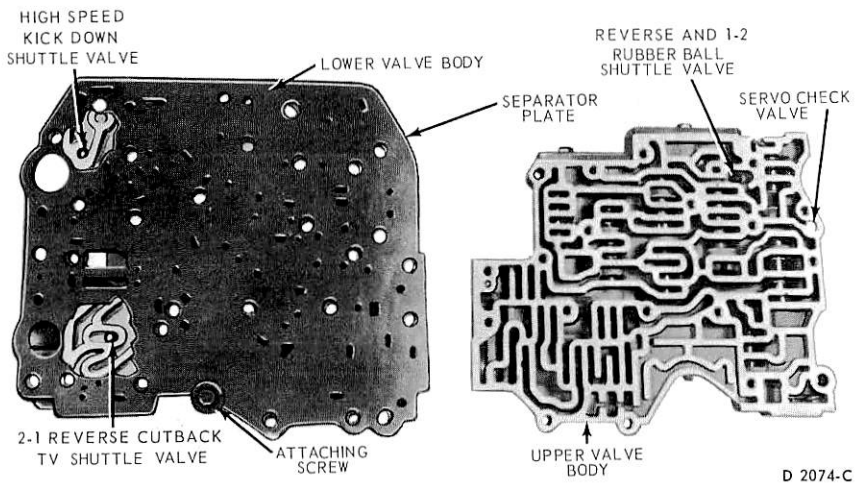

FIG. 51 Separating Upper and Lower Valve Bodies

LOW-REVERSE BRAKE DRUM BUSHING REMOVAL AND INSTALLATION

1. Replace the low-reverse brake drum bushing if it is worn or damaged. To remove the bushing, use the cape chisel and cut along the bushing seal until the chisel breaks through the bushing wall. Pry the loose ends of the bushing up with an awl and remove the bushing.
2. Install a new bushing with the tool shown in Fig. 85.

DESCRIPTION

Figure 1 shows the location of the converter, front pump, clutches, gear train and most of the internal parts used in the C6 transmission. The identification tag (Fig. 2), attached to the intermediate servo lower front cover bolt, includes the model prefix, suffix and serial number. The first line on the tag shows the transmission model prefix and suffix. A number appearing after the suffix (Fig. 2) indicates that the internal parts in the transmission have been changed after initial production start-up. For example, a PGB-AK model transmission that has been changed internally would read PGB-AK1. Both transmissions are basically the same, but some service parts in the PGB-AK1 transmission are slightly different than the PGB-AK transmission. Therefore, it is important that the codes on the transmission identification tag be checked when ordering parts or making inquiries about the transmission.

The C6 transmission is a three speed unit capable of providing automatic

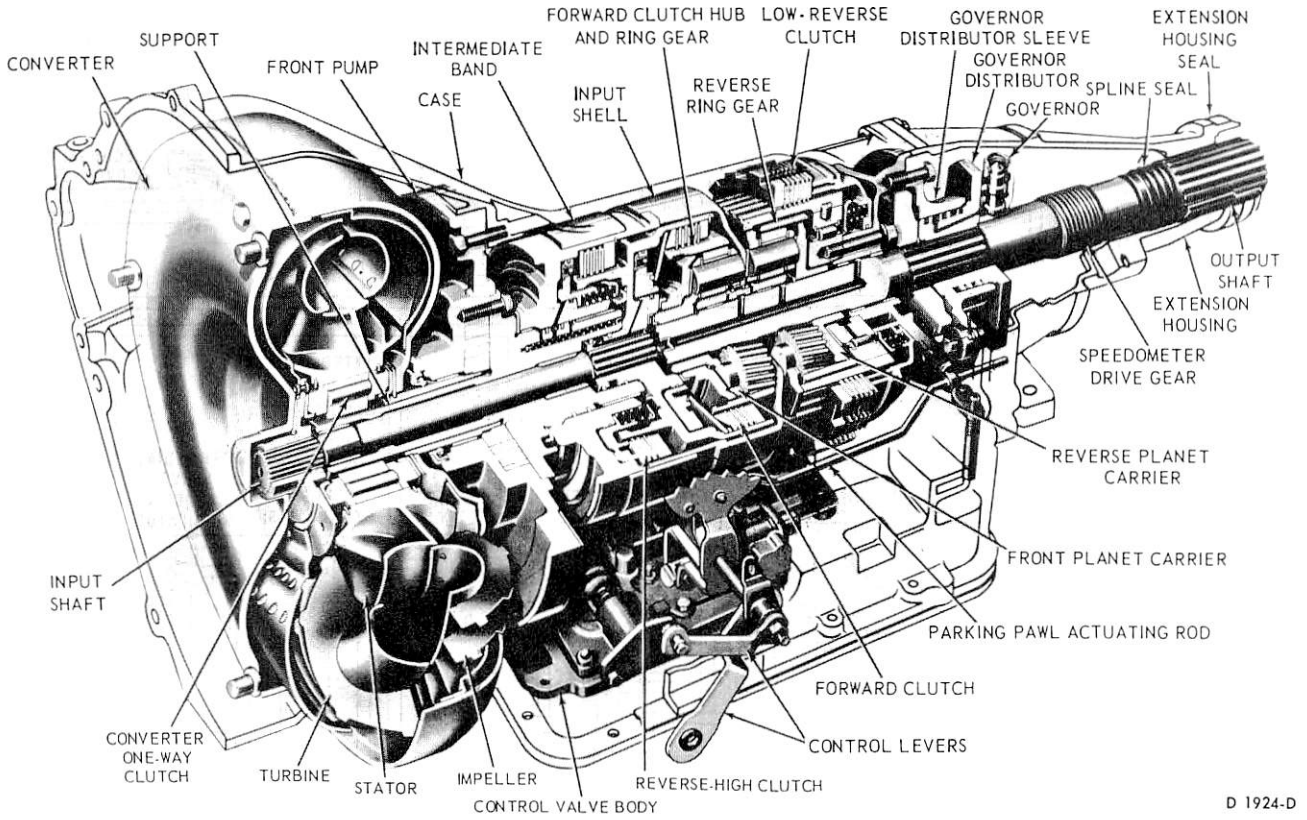

FIG. 1 C6 Automatic Transmission—Sectional

upshifts and downshifts through the three forward gear ratios, and also capable of providing manual selection of first and second gears. The hydraulic control system schematic is shown in Figure 3. The converter housing and the fixed splines which engage the splined OD of the low-reverse clutch steel plates, are both cast integrally into the case.

Only one (intermediate) band is used in the C6 transmission. This along with the forward clutch is used to obtain intermediate gear.

The only adjustment on the transmission proper is the intermediate band.

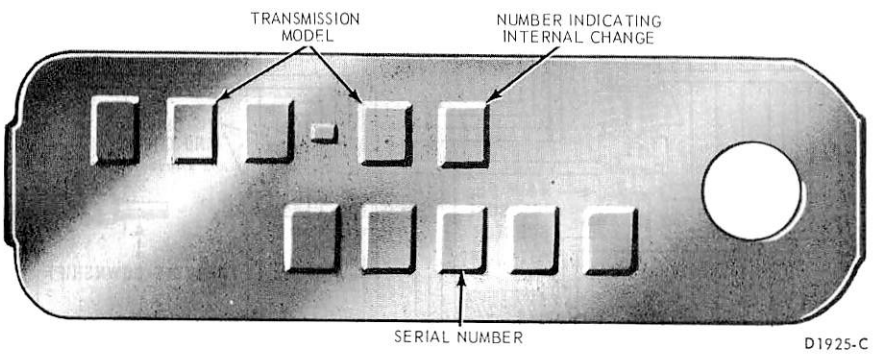

FIG. 2 Identification Tag

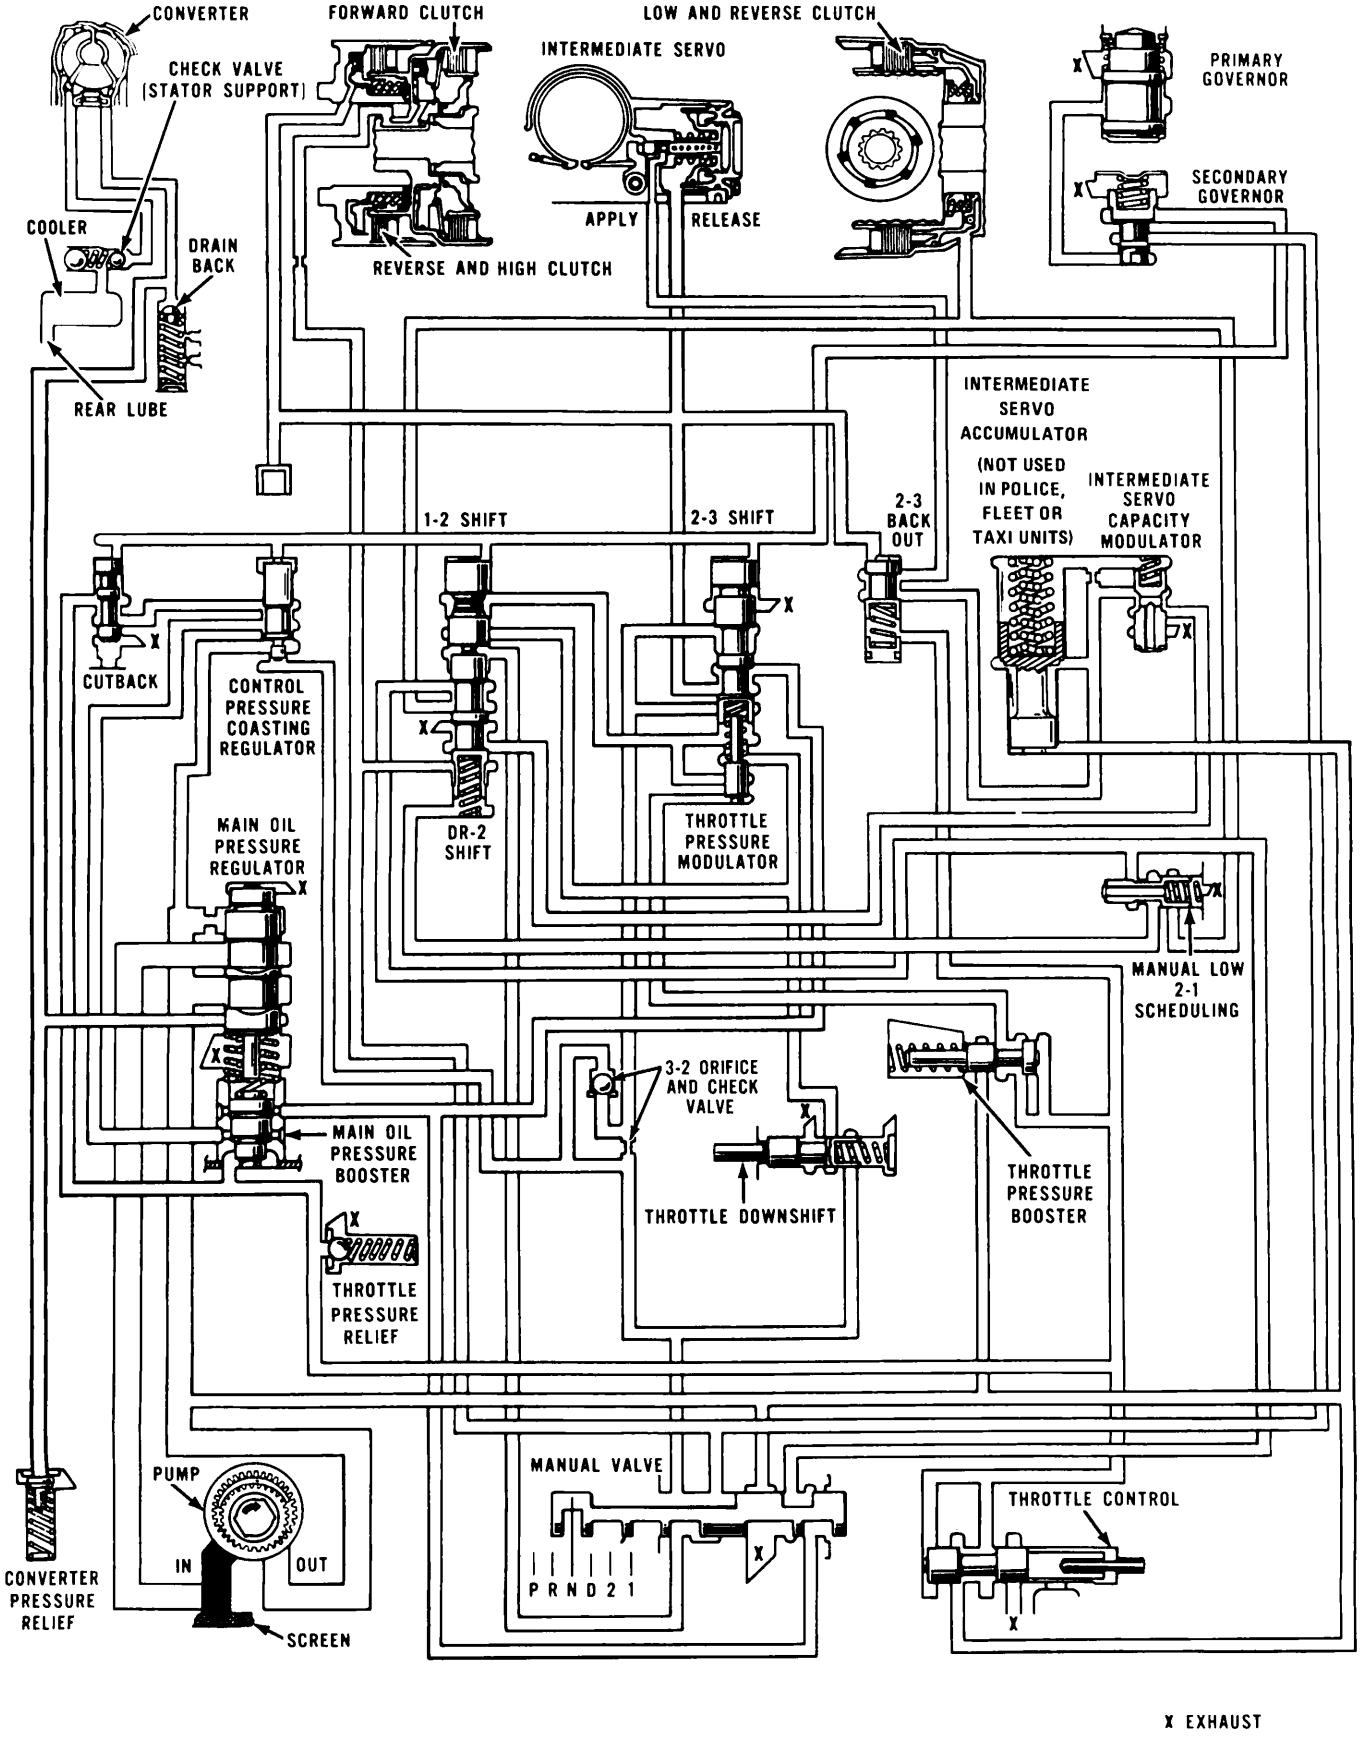

FIG. 3 Hydraulic Control System

ADJUSTMENTS

To prevent damage to the transmission and to assure proper band adjustment, it is essential that the tools and procedures described below are used whenever the band is adjusted.

INTERMEDIATE BAND ADJUSTMENT

1. Raise the vehicle on a hoist or jack stands.
2. Clean all the dirt from the band adjusting screw area. Remove and discard the locknut.
3. Install a new locknut and tighten the adjusting screw to 10 ft-lbs torque (Fig. 4).

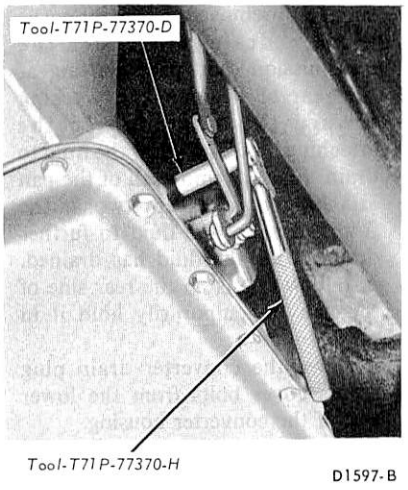

FIG. 4 Adjusting Intermediate Band

4. **Back off the adjusting screw exactly 1 1/2 turns.**
5. Hold the adjusting screw from turning and torque the locknut to specification.
6. Lower the vehicle.

REMOVAL AND INSTALLATION

TRANSMISSION

F-100, F-250 AND F-350

Removal

1. Drive the vehicle on a hoist, but do not raise at this time.
2. Remove the two upper converter housing-to-engine bolts.
3. Remove the bolt securing the fluid filler tube to the engine cylinder head.
4. Raise the vehicle on a hoist or stands.
5. Place the drain pan under the transmission fluid pan. Starting at the rear of the pan and working toward the front, loosen the attaching bolts and allow the fluid to drain. Finally remove all of the pan attaching bolts except two at the front, to allow the fluid to further drain. After the fluid has drained, install two bolts on the rear side of the pan to temporarily hold it in place.
6. Remove the converter drain plug access cover from the lower end of the converter housing.
7. Remove the converter-to-flywheel attaching nuts. Place a wrench on the crankshaft pulley attaching bolt to turn the converter to gain access to the nuts.
8. With the wrench on the crankshaft pulley attaching bolt, turn the converter to gain access to the converter drain plug. Then, remove the plug. Place a drain pan under the converter to catch the fluid. After the fluid has been drained from the converter, reinstall the plug.
9. Disconnect the crankshaft.
10. Disconnect the speedometer cable from the bearing retainer.
11. Disconnect the throttle and manual linkage rods from the levers at the transmission.
12. Disconnect the oil cooler lines from the transmission.
13. Remove the vacuum hoses from the vacuum unit. Remove the vacuum line retaining clips.
14. Disconnect the cable from the terminal on the starter motor. Remove the three attaching bolts and remove the starter motor.
15. Remove the two engine rear support crossmember-to-frame attaching bolts.
16. Remove the two engine rear support-to-extension housing attaching bolts.
17. Remove the eight bolts securing the No. 2 crossmember to the frame side rails.
18. Raise the transmission with a transmission jack and remove both crossmembers.
19. Secure the transmission to the jack with the safety chain.
20. Remove the remaining converter housing-to-engine attaching bolts.
21. Move the transmission away from the engine. Lower the transmission and remove it from under the vehicle.

Installation

1. Torque the converter drain plug to specification.
2. Position the converter to the transmission making sure the converter drive flats are fully engaged in the pump gear.
3. With the converter properly installed, place the transmission on the jack. Secure the transmission to the jack with the chain.
4. Rotate the converter so that the studs and drain plug are in alignment with their holes in the flywheel.
5. With the transmission mounted on a transmission jack, move the converter and transmission assembly forward into position, using care not to damage the flywheel and the converter pilot. **The converter must rest squarely against the flywheel. This indicates that the converter pilot is not binding in the engine crankshaft.**
6. Install and torque the converter housing-to-engine attaching bolts to specification.
7. Remove the transmission jack safety chain from around the transmission.
8. Position the No. 2 crossmember to the frame side rails. Install and torque the attaching bolts to specifications.
9. Position the engine rear support crossmember to the frame side rails. Install the rear support to extension housing mounting bolts and torque the bolts to specification.
10. Lower the transmission and remove the jack.
11. Secure the engine rear support crossmember to the frame side rails

with the attaching bolts and torque them to specification.
12. Connect the vacuum lines to the vacuum diaphragm making sure that the lines are in the retaining clips.
13. Connect the oil cooler lines to the transmission.
14. Connect the throttle and manual linkage rods to their respective levers on the transmission.
15. Connect the speedometer cable to the bearing retainer.
16. Secure the starter motor in place with the attaching bolts. Connect the cable to the terminal on the starter.
17. Install a new O-ring on the lower end of the transmission filler tube and insert the tube in the case.
18. Secure the converter-to-flywheel attaching nuts and torque them to specification.
19. Install the converter housing dust shield and secure it with the attaching bolts.
20. Connect the drive shaft.
21. Adjust the shift linkage.
22. Lower the vehicle. Then install the two upper converter housing-to-engine bolts and torque them to specification.
23. Position the transmission fluid filler tube to the cylinder head and secure with the attaching bolt.
24. Fill the transmission to the correct level with the specified lubricant.

B-600-700 AND F-600

Removal

1. From inside the vehicle, remove the six floor covering moulding retaining screws from the left side of the vehicle and remove the moulding. Position the floor covering out of the way.
2. Remove the three body bolt cover retaining screws and remove the cover. Remove the body bolt and nut.
3. Remove the two rear body bolt covers and loosen the body bolts substantially.
4. Raise the left side of the body with a jack and place a 1 5/8 inch piece of wood between the frame and body mounting surfaces. Lower the jack.
5. Connect a remote control starter button to the solenoid.
6. Remove the rear support-to-crossmember bolts and nuts.
7. With a transmission jack positioned at the rear of the engine, raise the engine and transmission high enough to remove the rear supports.
8. Place a drain pan under the transmission fluid pan. Starting at the rear of the pan and working toward the front, loosen the attaching bolts and allow the fluid to drain. Finally remove all of the pan attaching bolts except two at the front, to allow the fluid to further drain. After the fluid has drained, install two bolts on the rear side of the pan to temporarily hold it in place.
9. Remove the converter drain plug access cover bolts from the lower end of the converter housing.
10. Remove the converter-to-flywheel attaching nuts. Crank the engine to turn the converter to gain access to the nuts.
11. Crank the engine to gain access to the converter drain plug. Then, remove the plug. Place a drain pan under the converter to catch the fluid. After the fluid has been drained from the converter, reinstall the plug.
12. Disconnect the starter cable from the starter. Remove the three starter retaining bolts and remove the starter from the vehicle.
13. Disconnect the drive shaft at the transmission and position it out of the way.
14. Disconnect the speedometer cable.
15. Disconnect the parking brake linkage.
16. Disconnect the shift cable from the manual lever at the transmission.
17. Remove the two bolts that secure the shift cable bracket to the converter housing and position the cable and bracket out of the way.
18. Disconnect the downshift rod from the transmission downshift lever.
19. Disconnect the vacuum hoses from the vacuum diaphragm at the rear of the transmission. Remove the vacuum lines from the retaining clips at the transmission.
20. Disconnect the oil cooler lines from the transmission case.
21. Remove the bolt that secures the transmission filler tube to the cylinder block. Lift the filler tube and dipstick from the transmission.
22. Position a transmission jack under the transmission and secure the transmission to the jack with safety chain.
23. Remove the converter housing-to-engine attaching bolts.
24. Move the transmission assembly away from the engine. Tilt the assembly forward, and with the jack, guide it over the crossmember. Lower the transmission and remove it from the vehicle.
25. Remove the converter and mount the transmission in a holding fixture.

Installation

1. Torque the converter drain plug to specification.
2. Position the converter to the transmission making sure the converter drive flats are fully engaged in the pump gear.
3. With the converter properly installed, place the transmission on the jack. Secure the transmission to the jack with safety chain.
4. Rotate the converter so that the studs and drain plug are in alignment with their holes in the flywheel.
5. With the transmission mounted on the transmission jack, raise the transmission and position it over the crossmember to the engine. **Be careful not to damage the flywheel and converter pilot. The converter must rest squarely against the flywheel. This indicates that the converter pilot is not binding in the engine crankshaft.**
6. Install the converter housing-to-engine attaching bolts. Torque the bolts to specification. Remove the safety chain from the transmission.
7. Raise the engine and transmission and install the rear supports. With the supports in place, lower the assembly and install and torque the rear support-to-crossmember bolts and nuts.
8. Lower the jack and remove it from under the vehicle.
9. Install a new O-ring on the lower end of the transmission filler tube. Insert the tube in the transmission case and secure the tube to the engine with the attaching bolt.
10. Connect the vacuum lines to the vacuum diaphragm making sure that the lines are secured in the retaining clips.
11. Connect the oil cooler lines to the transmission case.
12. Connect the downshift rod to the lever on the transmission.
13. Position the shift cable bracket to the converter housing and install the attaching bolts.
14. Connect the shift cable to the manual lever at the transmission.
15. Connect the speedometer cable.
16. Connect the parking brake linkage.
17. Install the drive shaft.
18. Position the starter to the converter housing and secure it with the

attaching bolts. Connect the starter cable to the starter.
19. Install the torque converter-to-flywheel attaching nuts and torque them to specification.
20. Install the converter drain plug access cover. Torque the bolts to specification.
21. Disconnect the remote control starter button.
22. Using a jack, raise the left side of the body and remove the wood block previously installed. Lower the body to the frame and install the body bolt and nut. Position the cover over the body bolt and install the three attaching screws.
23. Tighten the two rear body bolts and nuts. Install the body bolt covers.
24. Reposition the floor covering. Install the moulding and secure with the six attaching screws.
25. Fill the transmission to the correct level with the specified fluid.
26. Adjust the transmission control linkage as required.
27. Check the transmission, converter assembly and oil cooler lines for leaks.

CONTROL VALVE BODY

Removal
1. Raise the vehicle on a hoist or jack stands.
2. Place a drain pan under the transmission and loosen the bolts to drain the fluid from the transmission.
3. Remove the transmission pan attaching bolts from both sides and the rear to allow the fluid to drain further. Finally, remove the remainder of the attaching bolts. Remove the pan and gasket. Remove and discard the nylon shipping plug from the filler tube hole. This plug is used to retain transmission fluid within the transmission during shipment and should be discarded when the oil pan is removed.
4. Remove the valve body attaching bolts and remove the valve body from the case.

Installation
1. Position the valve body to the case making sure that the selector and downshift levers are engaged, then install and torque the attaching bolts to specification.
2. Clean the transmission pan and gasket surfaces thoroughly.
3. Using a new pan gasket, secure the pan to the transmission case and torque the attaching bolts to specification.

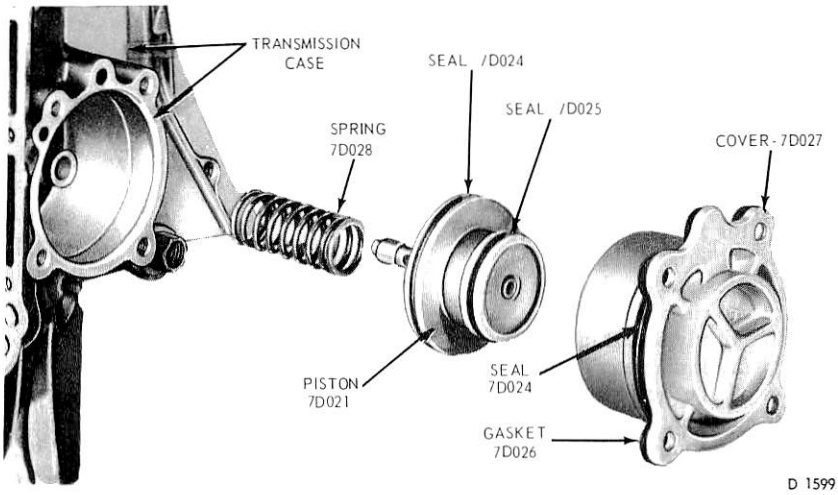

FIG. 5 Servo Disassembled

4. Lower the vehicle and fill the transmission to the correct level with the specified fluid.

INTERMEDIATE SERVO

Removal
1. Raise the vehicle on a hoist or jack stands.
2. Remove the bolt that secures the engine rear support to the crossmember.
3. Remove the two crossmember-to-frame attaching bolts.
4. Raise the transmission high enough to remove the weight from the crossmember and remove the crossmember.
5. Disconnect the muffler inlet pipe from the exhaust manifolds and allow the pipe to hang.
6. Place a drain pan under the servo. Remove the bolts that attach the servo cover to the transmission case.
7. Remove the cover, piston, spring and gasket from the case, screwing the band adjusting screw inward as the piston is removed. This insures that there will be enough tension on the band to keep the struts properly engaged in the band end notches while the piston is removed.

Seal Removal and Installation
1. Apply air pressure to the port in the servo cover to remove the piston and rod.
2. Remove the seals from the piston (Fig. 5).
3. Remove the seal from the cover.
4. Dip the new seals in transmission fluid.
5. Install the new seals on the piston and cover.
6. Coat two new gaskets with petroleum jelly and install the gaskets on the cover.
7. Dip the piston in transmission fluid and install it in the cover.

Installation
1. Position a new gasket on the servo cover.
2. Position the servo spring on the piston rod.
3. Insert the servo piston stem in the case. Secure the cover with the attaching bolts, taking care to back off the band adjusting screw as the cover bolts are tightened. Make sure that the service identification tag is in place.
4. Connect the muffler inlet pipe to the exhaust manifolds.
5. Raise the transmission high enough to install the crossmember. Secure the crossmember to the rear support with the attaching bolt. Lower the transmission as required to install the crossmember to frame attaching bolts. Torque the attaching bolts to specifications.
6. Remove the transmission jack.
7. Adjust the band as detailed in Adjustments.
8. Lower the vehicle and replenish the fluid as required.

EXTENSION HOUSING BEARING OR BUSHING AND REAR SEAL

F-100-250-350

Removal
1. Raise the vehicle and disconnect the the drive shaft at the transmission.
2. When only the rear seal needs replacing, carefully remove it with a tapered chisel or the tools shown in Fig. 6. Remove the bushing as shown in Fig. 7. **Use the bushing remover carefully so that the spline seal is not damaged.**

Installation

1. When installing a new bushing use the special tool shown in Fig. 8.
2. Before installing a new seal, inspect the sealing surface of the universal joint yoke for scores. If scores are found, replace the yoke.
3. Inspect the counterbore of the housing for burrs and if present, remove with crocus cloth.
4. Install the seal into the housing with the tool shown in Fig. 9. The seal should be firmly seated in the bore. Coat the inside diameter of the fiber portion of the seal with C1AZ-19590-B lubricant.
5. Coat the front universal joint spline with C1AZ-19590-B lubricant and install the drive shaft.

B-600-700 AND F-600

Removal

1. Raise the vehicle and disconnect the drive shaft. If a parking brake drum is mounted on the transmission, remove the drum. Remove the transmission output shaft yoke attaching nut and yoke.
2. Remove the five bolts securing the bearing retainer to the extension housing and remove the retainer.
3. Remove the seal from the retainer.
4. To remove the output shaft bearing from the extension housing, remove the bearing retaining snap ring.
5. Using a suitable puller, remove the bearing from the extension housing.

Installation

1. Using a suitable tool, install a new bearing in the extension housing. Install the bearing retaining snap ring.
2. Using a suitable tool, install a new seal in the bearing retainer.
3. Position a new bearing retainer-to-extension housing gasket on the extension housing.
4. Position the bearing retainer to the extension housing and install the attaching bolts. Install the brake drum, if so equipped.
5. Install the output shaft yoke and retaining nut. torque the attaching nut to specification.
6. Connect the drive shaft and lower the vehicle.

EXTENSION HOUSING

F-100-250-350

Removal

1. Raise the vehicle on a hoist or stands.
2. Disconnect the drive shaft from the rear axle flange and remove it from the transmission.
3. Disconnect the speedometer cable from the extension housing.

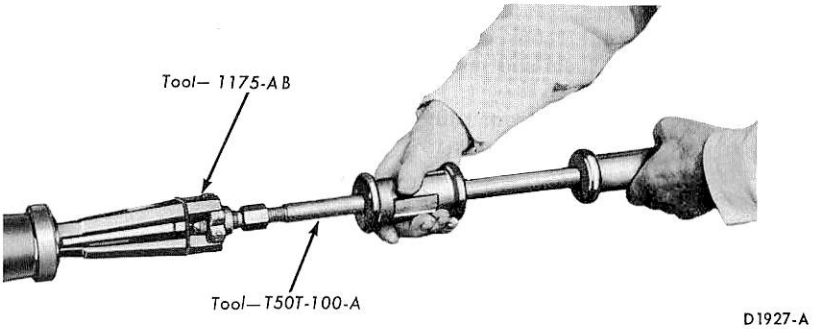

FIG. 6 Removing Extension Housing Seal

4. Remove the engine rear support-to-extension housing attaching bolts.
5. Place a jack under the transmission and raise it just enough to remove the weight from the engine rear support.
6. Remove the bolt that secures the engine rear support to the crossmember and remove the support.
7. Place a drain pan under the rear of the transmission case.
8. Lower the transmission and remove the extension housing attaching bolts. Slide the extension housing off the output shaft and allow the fluid to drain.

Installation

1. Clean the mounting surface on the transmission and on the extension housing. Position a new gasket on the transmission.
2. Hold the extension housing in place and secure it with the attaching bolts.
3. Raise the transmission high enough to position the engine rear support on the crossmember.
4. Secure the support to the crossmember with the attaching bolt and nut. Torque the bolt to specification.
5. Lower the transmission and remove the jack. Install and torque the engine rear support-to-extension housing attaching bolts to specification.
6. Secure the speedometer cable to the extension housing with the attaching bolt.
7. Install the drive shaft.
8. Fill the transmission to the correct level with the specified fluid.

B-600-700 AND F-600

Removal

1. Raise the vehicle on a hoist or jack stands.
2. Disconnect the drive shaft at the transmission output shaft yoke and position it out of the way. If a

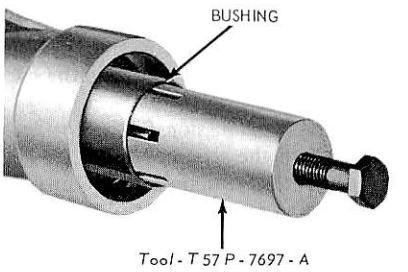

FIG. 7 Removing Extension Housing Bushing

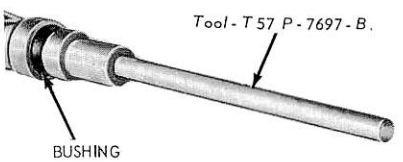

FIG. 8 Installing Extension Housing Bushing

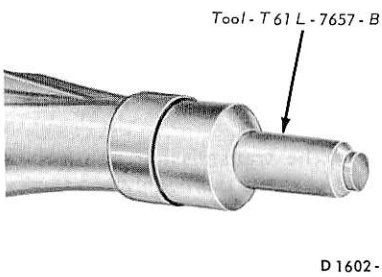

FIG. 9 Installing Extension Housing Seal

parking brake drum is mounted on the transmission, remove the drum.
3. Disconnect the speedometer cable from the extension housing bearing retainer.
4. Remove the engine rear support-to-extension housing attaching bolts.
5. Place a jack under the transmission and raise it just enough to remove the weight from the engine rear support.
6. Remove the bolt that secures the engine rear support to the crossmember and remove the support.
7. Place a drain pan under the rear of the transmission case.
8. Remove the transmission output shaft yoke attaching nut and yoke.
9. Remove the rear bearing retainer-to-extension housing bolts and remove the retainer.
10. Remove the rear bearing retaining snap ring and remove the rear bearing from the extension housing.
11. Remove the extension housing-to-case attaching bolts and slide the extension housing off the output shaft.

Installation

1. **Clean the mounting surface on the transmission and on the extension housing. Position a new gasket on the transmission.**
2. Hold the extension housing in place and secure it with the attaching bolts.

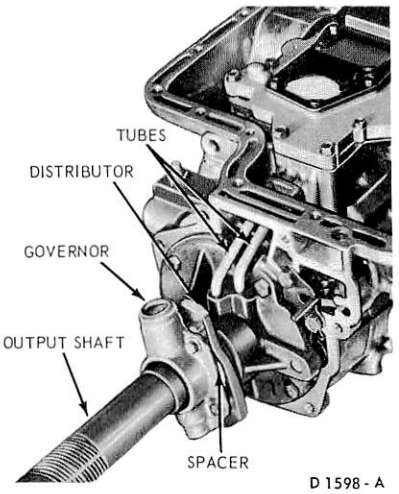

FIG. 10 Governor Installed

3. Install the bearing in the extension housing with Tool T53T-7065-B. Install the bearing retaining snap ring.
4. Position a new bearing retainer-to-extension housing gasket on the extension housing.
5. Position the bearing retainer to the extension housing and install the attaching bolts. Install the brake drum, if so equipped.
6. Install the output shaft yoke and retaining nut. Torque the attaching nut to specification.
7. Raise the transmission high enough to position the engine rear support on the crossmember.
8. Secure the support to the crossmember with the attaching bolt and nut. Torque the bolt to specification.
9. Lower the transmission and remove the jack. Install and torque the engine rear support-to-extension housing attaching bolts to specification.
10. Connect the speedometer cable to the bearing retainer.
11. Install the drive shaft.
12. Lower the vehicle and fill the transmission to the correct level with the specified fluid.

GOVERNOR

Removal

1. Remove the extension housing as outlined in this section of the manual.
2. Remove the governor housing-to-flange attaching bolts (Fig. 10).
3. Remove the governor from the flange.
4. Refer to Disassembly and Assembly of this Part for governor repair operations.

Installation

1. Secure the governor (Fig. 10) to the distributor flange with the attaching bolts. Torque the bolts to specification.
2. Reinstall the extension housing.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

During the repair of the subassemblies, certain general instructions which apply to all units of the transmission must be followed. Following these instructions will avoid unnecessary repetition.

All transmission parts must be handled carefully to avoid nicking or burring the bearing or mating surfaces.

Lubricate all internal parts of the transmission with clean automatic transmission fluid before assembling them.

Do not use any other lubricants except on gaskets and thrust washers. These may be coated with vaseline to facilitate assembly. Always use new gaskets and seals when assembling a transmission.

Tighten all bolts and screws to the recommended torque as outlined in the Specification Section.

Disassembly

1. Mount the transmission in holding fixture T64L-6001-A.
2. Remove the 17 fluid pan attaching bolts. Remove the pan and gasket.
3. Remove the 8 valve body attaching bolts (Fig. 11). Lift the valve body from the transmission case.
4. Attach a dial indicator to the front pump as shown in Fig. 12. Install Tool T61L-7657-B in the extension housing to center the shaft.
5. Pry the gear train to the rear of the case and at the same time, press the input shaft inward until it bottoms (Fig. 12). Set the dial indicator to read zero.
6. Pry the gear train forward (Fig. 12) and note the amount of gear train end play on the dial indicator. Record the end play to facilitate assembling the transmission. Remove the dial indicator from the pump and the tool from the extension housing.
7. Remove the vacuum diaphragm, rod and the primary throttle valve from the case. Slip the input shaft out of the front pump.
8. Remove the front pump attaching bolts. Pry the gear train forward as shown in Fig. 13 to remove the pump.
9. Loosen the band adjustment screw and remove the two struts.
10. Rotate the band 90 degrees counterclockwise to align the ends with the slot in the case (Fig. 14). Slide the band off the reverse-high clutch drum.
11. Remove the forward part of the gear train as an assembly as shown in Fig. 15.
12. Remove the large snap ring that secures the reverse planet carrier in

the low-reverse clutch hub. Lift the planet carrier from the drum.

13. Remove the snap ring (Fig. 16) that secures the reverse ring gear and hub on the output shaft. Slide the ring gear and hub off the shaft.
14. Rotate the low-reverse clutch hub in a clockwise direction and at the same time, withdraw it from the case.
15. Remove the reverse clutch snap ring from the case, then remove the clutch discs, plates and pressure plate from the case.
16. If a parking brake drum is mounted on the transmission, remove the drum. Remove the extension housing attaching bolts and vent tube from the case. Remove the extension housing and gasket.
17. Slide the output shaft assembly from the transmission case.
18. Remove the distributor sleeve attaching bolts and remove the sleeve, parking pawl gear and the thrust washer.

If the thrust washer is staked in place, use a sharp chisel and cut off the metal from behind the thrust washer. Be sure to clean the rear of the case with air pressure or a suitable solvent to remove any metal particles.

19. Compress the reverse clutch piston release spring with Tool T65L-77515-A (Fig. 17). Remove the snap ring. Remove the tool and the spring retainer.
20. Remove the one-way clutch inner race attaching bolts from the rear of the case. Remove the inner race from inside of the case.
21. Remove the reverse clutch piston from the case as shown in Fig. 18.

Assembly

1. Place the transmission case in a holding fixture.
2. Position the low-reverse clutch piston so that the check ball is in the 6 o'clock position (toward bottom of case next to oil pan) and tap the piston into place in the case with a clean rubber hammer.
3. Hold the one-way clutch inner race in position and install and torque the attaching bolts to specification.
4. Install a low-reverse clutch return spring in each pocket in the clutch piston. Press the springs firmly into the piston to prevent them from falling out.
5. Position the spring retainer over the springs and position the retainer snap ring in place on the one-way clutch inner race.
6. Install the compressing tool shown in Fig. 17 and compress the springs

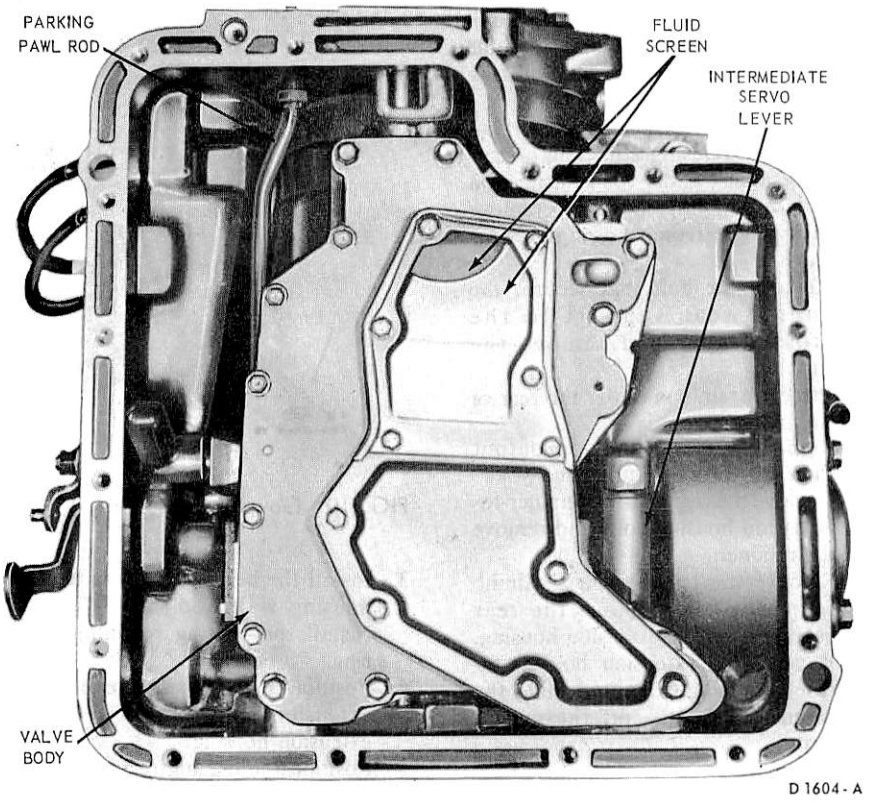

FIG. 11 Transmission With Pan Removed

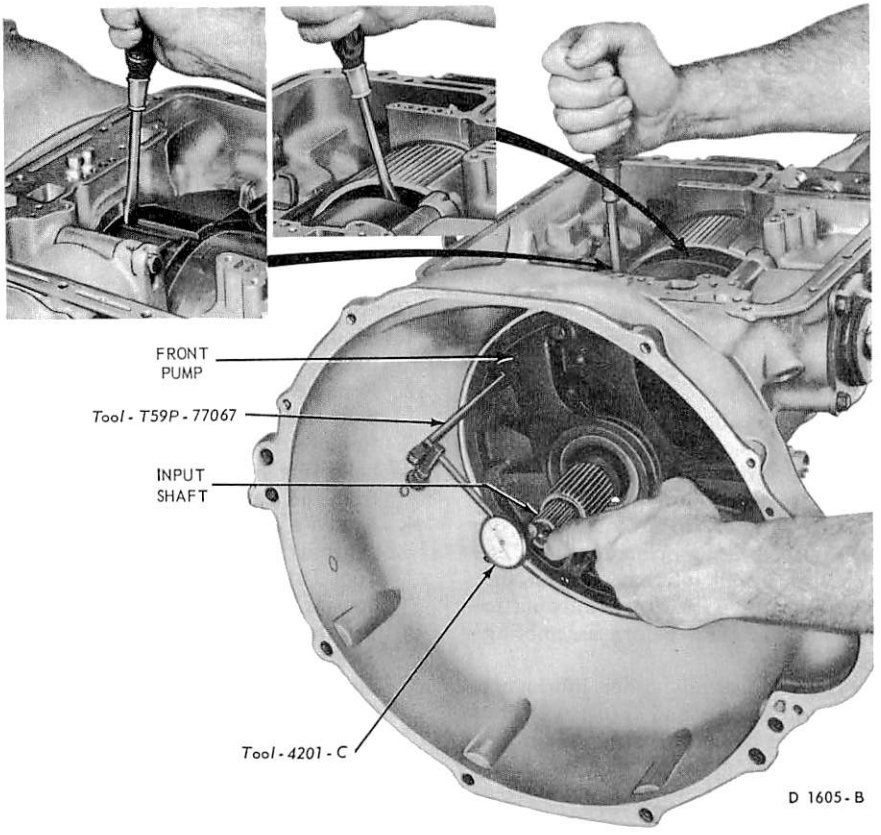

FIG. 12 Checking Gear Train End Play

just enough to install the low-reverse clutch piston retainer snap ring.

7. Install the snap ring, then remove the compressing tool.
8. Place the transmission case on the bench with the front end facing downward.
9. Position the parking gear thrust washer and the gear on the case (Fig. 27). **Do not restake the thrust washer.**

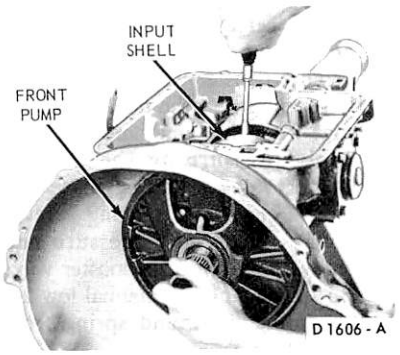

FIG. 13 Removing Front Pump

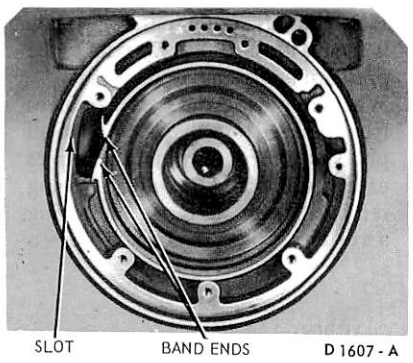

FIG. 14 Removing or Installing Band

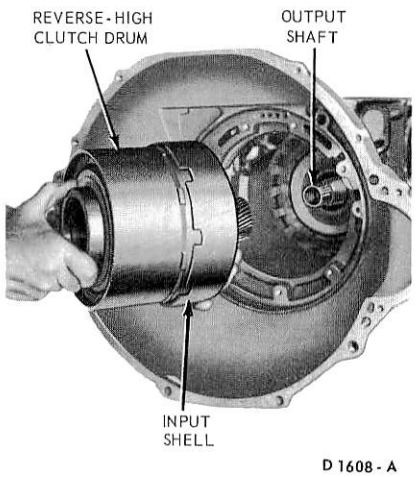

FIG. 15 Removing or Installing Forward Part of Gear Train

10. Position the oil distributor and tubes in place on the rear of the case. Install and torque the attaching bolts to specification.
11. Install the output shaft, and governor as an assembly.
12. Place a new gasket on the rear of the transmission case. Position the extension housing on the case and install the attaching bolts. Torque the attaching bolts to specification. Install the brake drum, if so equipped.
13. Place the case in the holding fixture.
14. Align the low-reverse clutch hub and one-way clutch with the inner race at the rear of the case. Rotate the low-reverse clutch hub clockwise while applying pressure to seat it on the inner race.
15. Install the low-reverse clutch plates, starting with a steel plate and following with friction and steel plates alternately. Retain them with vaseline. Refer to the Specifications Section for the number of plates required. If new composition plates are being used, soak them in clean transmission fluid for fifteen minutes before installation. Install the pressure plate and the snap ring. Test the operation of the low-reverse clutch by applying air pressure at the clutch pressure apply hole in the case.
16. Install the reverse planet ring gear thrust washer and the ring gear and hub assembly. Insert the snap ring in the groove in the output shaft.
17. Assemble the front and rear thrust washers onto the reverse planet assembly; retain with vaseline. Insert the assembly into the ring gear and install the snap ring.
18. Set the reverse-high clutch on the bench, with the front end facing down. Install the thrust washer on the rear end of the reverse-high clutch assembly. Retain the thrust washer with vaseline and insert the splined end of forward clutch into the open end of the reverse-high clutch so that the splines engage the direct clutch friction plates (Fig. 34).
19. Install the thrust washer and retain it with vaseline, on the front end of the forward planet ring gear and hub. Insert the ring gear into the forward clutch.
20. Install the thrust washer on the front end of the forward planet assembly. Retain the washer with vaseline and insert the assembly into the ring gear. Install the input shell and sun gear assembly.
21. Install the reverse-high clutch, forward clutch, forward planet assembly and drive input shell and sun gear as an assembly into the transmission case.
22. Insert the intermediate band into the case around the direct clutch cylinder. Install the struts and then tighten the band adjusting screw sufficiently to retain the band.

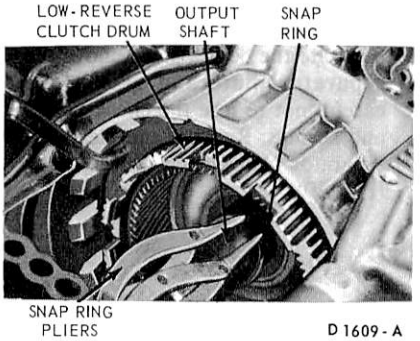

FIG. 16 Removing or Installing Reverse Ring

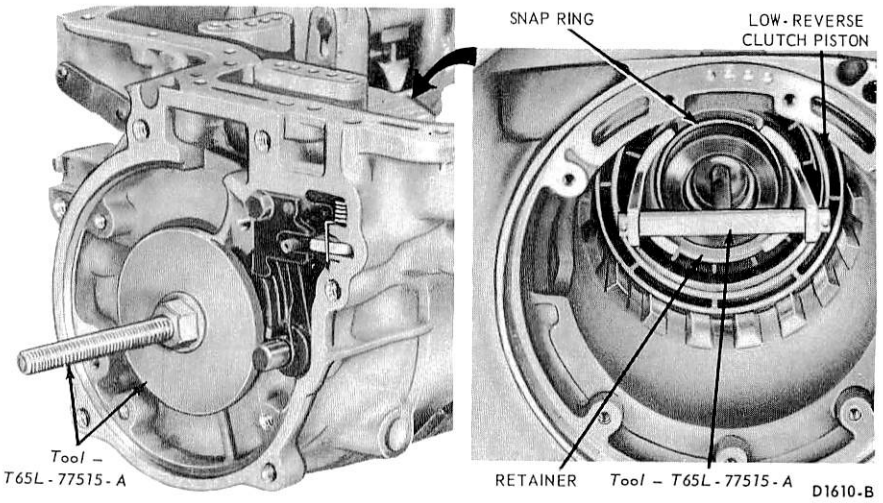

FIG. 17 Compressing Reverse Clutch Springs

23. Place a selective thickness bronze thrust washer on the rear shoulder of the stator support and retain it with vaseline. If the end play was not within specification when checked prior to disassembly, replace the washer with one of proper thickness. Refer to Specifications Section for selective thrust washer thicknesses. Lay a new gasket on the rear mounting face of the pump and position on the case being careful not to damage the large seal on the OD of the pump housing. Install six of the seven mounting bolts and torque them to specification.
24. Adjust the intermediate band as detailed in Adjustments and install the input shaft with the long splined end inserted into the forward clutch assembly.

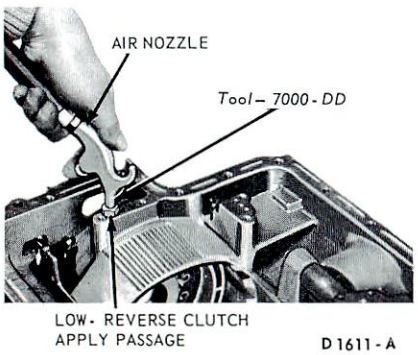

FIG. 18 Removing Low-Reverse Clutch Piston

25. Install Tool 4201-C at the seventh pump mounting bolt (Fig. 12) and check the transmission end play. Remove the tool.
26. Install the control valve in the case, making sure that the levers engage the valves properly. Install the primary throttle valve, rod, and the vacuum diaphragm in the case.
27. Install a new pan gasket and the pan.
28. Install the converter assembly.
29. Install the transmission in the vehicle.

CONTROL VALVE BODY

Disassembly

When the main control is disassembled and the valve body-to-screen gasket is removed, the gasket should not be cleaned in a degreaser, solvent or any type of detergent solution. To clean the gasket, wipe it off with a lint-free cloth.

1. Remove the nine screws that attach the screen to the lower valve body (Fig. 19) and remove the screen and gasket (Fig. 20).
2. Remove the five upper-to-lower valve body and hold-down plate attaching screws. Remove the seven attaching screws from the underside of the lower valve body (Fig. 19).
3. Separate the bodies and remove the separator plate and gasket. Be careful not to lose the check valves and springs. Remove and clean the separator plate screen if necessary (Fig. 20).
4. Remove the manual valve plunger retaining pin from the upper valve body and remove the plunger.
5. Slide the manual valve (Fig. 21) out of the valve body.
6. Cover the downshift valve port with a finger, then working from the underside of the body remove the downshift valve retainer. Remove the spring and downshift valve.
7. Apply pressure on the pressure booster valve retaining plate and remove the two attaching screws. Slowly release the pressure and remove the plate, sleeve and the pressure booster valve. Remove the two springs and the main regulator valve from the same bore.
8. Apply pressure on the throttle booster valve retaining plate and remove the two attaching screws. Slowly release the pressure and remove plate, throttle booster valve and spring, and the manual low 2-1 scheduling valve and spring from the body.
9. Apply pressure on the remaining valve retaining plate and remove the eight attaching screws.
10. Hold the valve body so that the plate is facing upward. Slowly release the pressure and remove the plate.
11. When removing the various valves from the control valve body, keep all ports covered with your fingers except the bore the valve is being removed from. Remove the spring and the intermediate servo

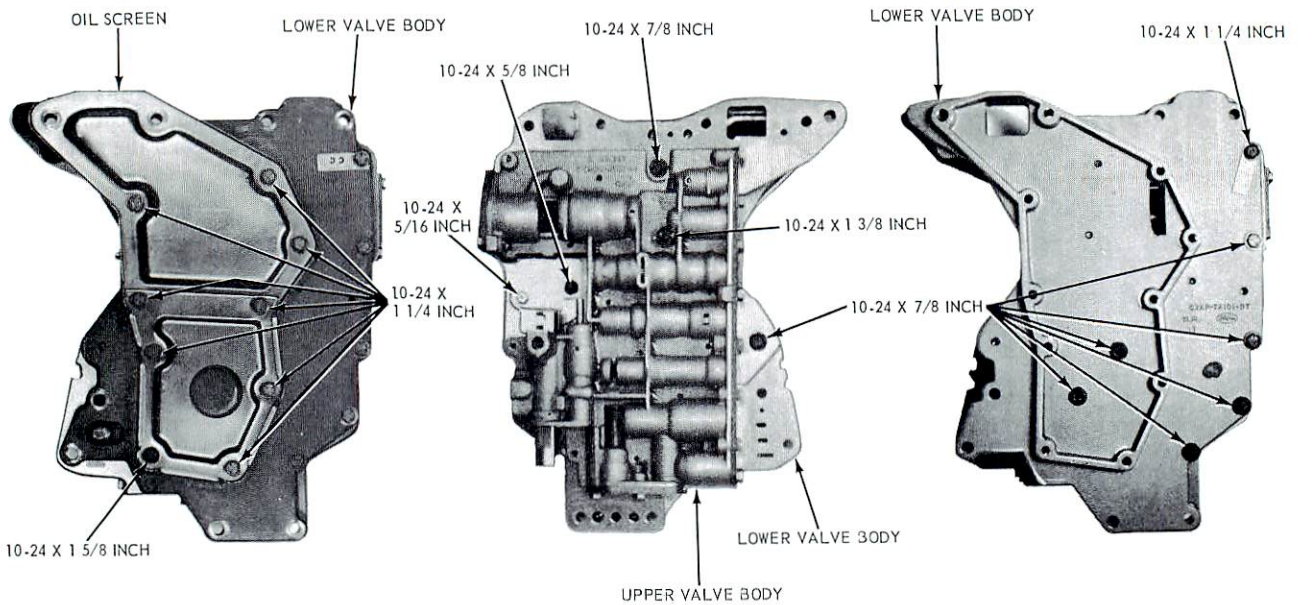

FIG. 19 Control Valve Body and Screen Attaching Screws

modulator valve (Fig. 21) from the valve body.
12. Remove the intermediate servo accumulator valve and springs.
13. Remove the 2-3 back-out valve, spring and 3-2 shift timing valve plug. Do not remove the 3-2 shift timing valve plug if it is found to be peened, preventing its removal. This condition will not affect transmission operation and is not cause for replacement of the main control.
14. Remove the 2-3 shift valve, spring and the throttle modulator valve.
15. Remove the 1-2 shift valve, D2 shift valve and the spring from the valve body.
16. Remove the coasting regulator valve from the body.
17. Remove the cutback control valve to complete the disassembly of the control valve.

Assembly

1. Place the 3-2 shift timing valve plug in the valve body if it was previously removed.
2. Place the downshift valve and spring in the valve body. Compress the spring and install the retainer from the underside of the body (Fig. 22).
3. Place the valve body on a clean surface with the passage side facing up. Place the converter relief valve spring in its bore (Fig. 22). Coat the converter relief valve check valve with vaseline and place it on top of the spring. Place the 2-3 shift check valve ball in its cavity. Place the throttle pressure relief valve spring in its bore (Fig. 22). Coat the throttle pressure relief valve check ball with vaseline and place it on top of the spring.
4. Install the separator screen in the separator plate if it was previously removed. Be sure the screen tabs are flush with the separator plate surface. Carefully position the separator plate and new gasket on the lower valve body. Place the two hold-down plates on the separator plate and install the attaching screws finger tight.
5. Place the lower body and plate assembly on the upper valve body and install the attaching screws finger tight (Fig. 19).
6. Install the oil screen screws loosely, without the screen, to properly align the upper and lower valve bodies, gasket and separator plate.
7. Torque the two bolts that are covered by the screen to specification.
8. Remove the oil screen attaching screws and place the gasket and oil screen in position on the lower valve body. Reinstall the screen attaching screws (Fig. 19).
9. Torque all the valve body and screen attaching screws to specification.
10. Place the cutback control valve (Fig. 21) in the valve body.
11. Place the coasting regulator valve in the body.
12. Place the spring D2 shift valve and the 1-2 shift valve in the body.
13. Place the throttle modulator valve and spring and the 2-3 shift valve in the valve body.
14. Place the spring and the 2-3 backout valve in the valve body.
15. Place the two springs and the intermediate servo accumulator valve in the valve body.
16. Place the intermediate servo modulator valve and spring in the body.
17. Carefully place the valve retaining plate on the body and secure it with the eight attaching screws. Tighten the screws to specification.
18. Place the throttle booster valve and spring in the valve body. Place the manual low 2-1 scheduling valve and spring in the valve body and install the retaining plate. Torque the attaching screws to specification.
19. Place the main regulator, two springs, pressure booster valve and the sleeve in the valve body.
20. Install the pressure booster plate and torque the two attaching screws to specification.
21. Place the manual valve in the valve body and install the plunger and the retaining pin in the body.

INTERMEDIATE SERVO

Disassembly

1. Apply air pressure to the port in the servo cover to remove the piston and rod.
2. Remove the seals from the piston.
3. Remove the seal from the cover.

Assembly

1. Dip the new seals in transmission fluid.

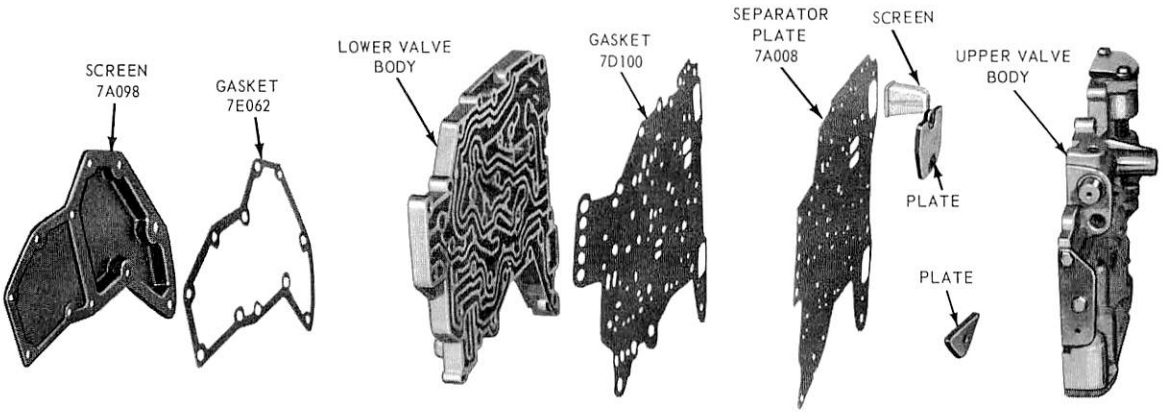

FIG. 20 Upper and Lower Valve Bodies Disassembled

D1969-F

FIG. 23 Intermediate Servo Cover and Piston Dimensions

2. Install new seals on the cover and servo piston. Fig. 23 shows the correct servo piston and cover for the transmission.
3. Dip the piston in transmission fluid and install it in the cover.

GOVERNOR

Disassembly

1. Remove the governor attaching bolts and remove the governor.
2. Remove the snap ring that secures the governor distributor on the output shaft (Fig. 24) and slide it off the front of the shaft.
3. Remove the seal rings from the distributor.

Assembly

1. Carefully install new seal rings on the distributor.
2. Working from the front end of the output shaft, slide the governor distributor into place on the shaft. Install the snap ring to secure it. Make sure that the snap ring is seated in the groove.
3. Position the governor on the distributor (Fig. 24) and secure them with the attaching screws.

DOWNSHIFT AND MANUAL LINKAGE

Disassembly

1. Remove the nut and lockwasher that secures the outer downshift lever to the transmission and remove the lever.
2. Slide the downshift lever out from the inside of the case (Fig. 25). Remove the seal from the recess in the manual lever shaft.
3. Remove the C-ring that secures the parking pawl actuating rod to the manual lever. Remove the rod from the case.
4. Remove the nut that secures the inner manual lever to the shaft. Remove the inner lever from the shaft. Slide the outer lever and shaft from the case.

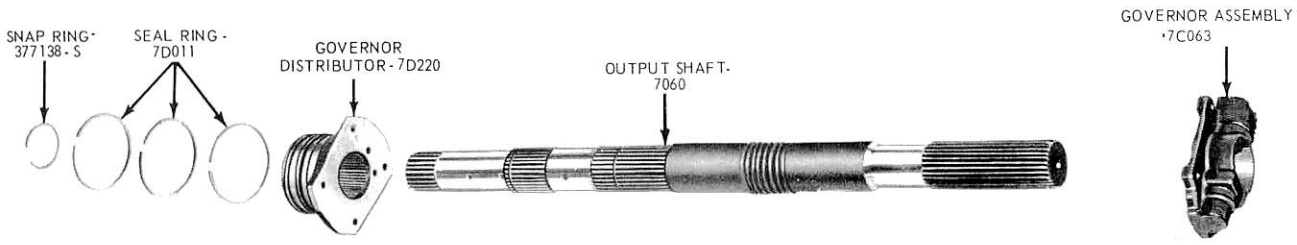

FIG. 24 Output Shaft Disassembled

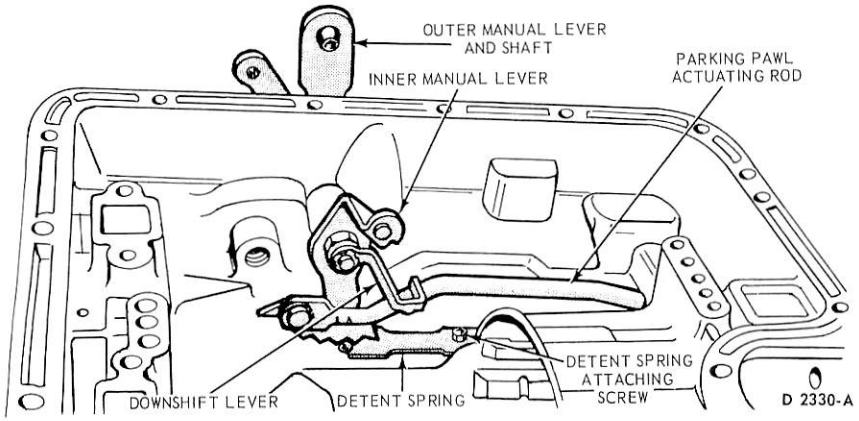

FIG.25 Downshift and Manual Linkage

5. Remove the seal from the case with Tools T59L-100-B and T58L-101-A or 7600-E.
6. Dip the new seal in transmission fluid and install it in the case as shown in Fig. 26.

Assembly

1. Slide the outer manual lever and shaft in the transmission case.
2. Position the inner lever on the shaft making sure the leaf spring roller is positioned in the inner manual lever detent. Install the attaching nut. Tighten the nut to specification. Install the parking pawl actuating rod and secure it to the inner manual lever with a C-washer.
3. Install a new downshift lever seal in the recess of the outer lever shaft. Slide the downshift lever and shaft into position.
4. Place the outer downshift lever on the shaft and secure it with a lockwasher and nut.

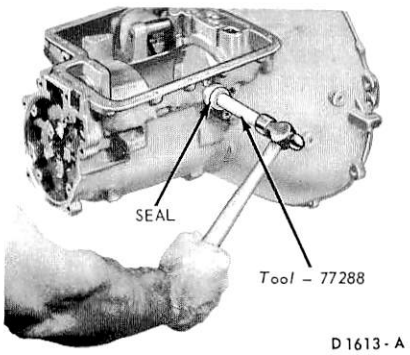

FIG. 26 Installing Manual Lever Seal

PARKING PAWL LINKAGE (F-100, F-250 AND F-350 ONLY)

Disassembly

1. Remove the bolts that secure the parking pawl guide plate to the case (Fig. 27). Remove the plate.
2. Remove the spring, parking pawl and shaft from the case.
3. Working from the pan mounting surface, drill a 1/8 inch diameter hole through the center of the cupped plug. Pull the plug from the case with a wire hook.
4. Unhook the end of the spring from the park plate slot to relieve the tension.
5. Thread a 1/4-20 inch or 8-32 x 1 1/4 inch screw (Fig. 28) into the park plate shaft. Pull the shaft from the case with the screw.

Assembly

1. Position the spring and park plate in the case and install the shaft. Place the end of the spring into the slot of the park plate.
2. Install a new cupped plug (Fig. 27) to retain the shaft.
3. Install the parking pawl shaft in the case. Slip the parking pawl and spring into place on the shaft.
4. Position the guide plate on the case making sure that the actuating rod is seated in the slot of the place. Secure the plate with two bolts and lockwashers.

SERVO APPLY LEVER

Disassembly

1. Working from inside of the transmission case, carefully drive on the servo apply lever shaft to remove the cup plug. The shaft (Fig. 29) can be withdrawn from the case by hand.

Assembly

1. Hold the servo apply lever in position and install the new shaft.
2. Using the fabricated tool shown in Fig. 29, drive the cup plug into position in the case. Be sure the plug is flush with the shoulder of the counterbore. The cup plug may be coated with Loctite, Part No. C3AZ-19554-A, before installation.

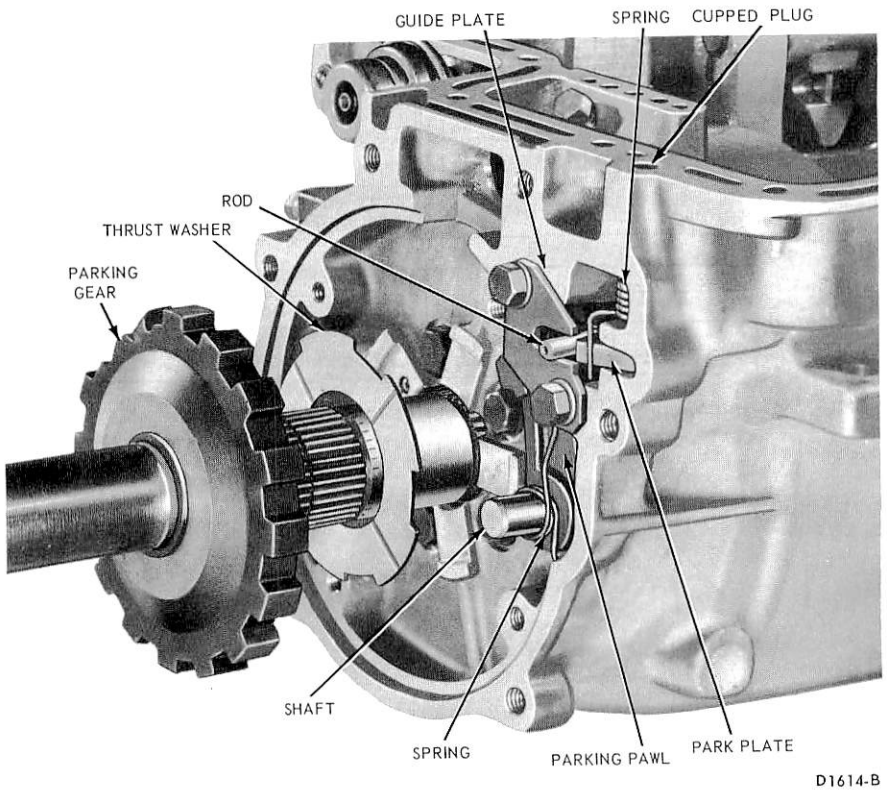

FIG. 27 Parking Pawl Mechanism

FRONT PUMP

The front seal can be replaced after the pump has been installed on the transmission (Figs. 30 and 31).

Disassembly

1. Remove the two seal rings and the selective thrust washer (Fig. 32).
2. Remove the large square-cut seal from the O.D. of the pump housing.
3. Remove the 5 bolts that secure the pump support to the pump housing. Lift the support from the housing.
4. Remove the drive and the driven gear from the housing.
5. If the pump housing bushing is worn or damaged, replace it using the handle and tool shown in Fig. 33.

Assembly

1. Install the drive and driven gears in the pump housing. Each gear has an identification mark on one face. **The identification mark on each gear must be installed toward the front of the pump housing.**
2. Position the pump support in the pump housing and install and torque the five attaching bolts to specification.
3. Carefully install two new seal rings on the pump support. Make sure that the ends of the rings are engaged to lock them in place. Install a new square-cut seal on the O.D. of the pump housing.
4. Install the selective thrust washer. Make sure that the correct thickness selective washer is being used to obtain the specified end play.
5. Place the pump on the converter making sure that the drive gear engages the converter hub. Rotate the pump to make sure that the gears rotate freely.

REVERSE-HIGH CLUTCH

Disassembly

1. Separate the drive train as shown in Fig. 34. Remove the pressure plate retaining snap ring as shown in Fig. 35.
2. Remove the pressure plate and the drive and driven clutch plates (Fig. 36).
3. Install Tool T65L-77515-A (Fig. 37) on the reverse-high clutch drum. Make sure that the legs clear the snap ring enough to permit expanding it enough for removing it. Remove the snap rings and remove the tool.
4. Remove the spring retainer and the piston return springs.
5. Apply air pressure to the piston apply hole in the clutch hub (Fig. 38) and remove the piston.
6. Remove the piston outer seal from the piston and the inner seal from the clutch drum (Fig. 36).
7. Remove the front and rear bushings from the clutch drum if they are worn or damaged. To remove the front bushing, use a cape chisel and cut along the bushing seam until the chisel breaks through the bushing wall. Pry the loose ends of the bushing up with an awl and remove the bushing.

To remove the rear bushing, use the tool shown in Fig. 39, and press the bushing from the drum.

Assembly

1. If the clutch drum bushings were removed, position the drum in a press and press new bushings into the drum with the tools shown in Figs. 39 or 40.
2. Dip the new seals in transmission fluid and install one on the drum and one on the piston.
3. Install the piston in the clutch drum.
4. Position the piston return springs in the piston sockets (Fig. 41). Place the spring retainer on the springs.
5. Install Tool T65L-77515-A (Fig. 37) and compress the springs. Make certain that the spring retainer is centered while compressing the springs. Install the snap ring. Before releasing the pressure on the tool, make certain that the snap ring is positioned inside of the four snap ring guides on the spring retainer.
6. Clutch plate usage varies with each model, refer to the Specifications

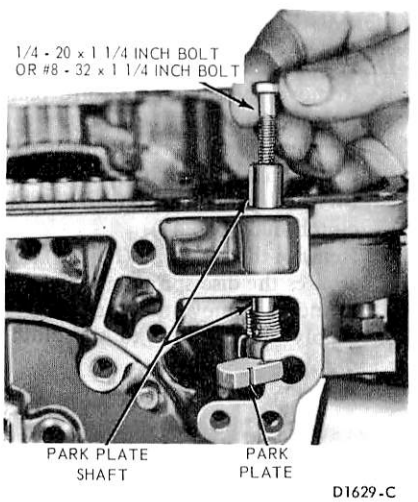

FIG. 28 Removing Park Plate

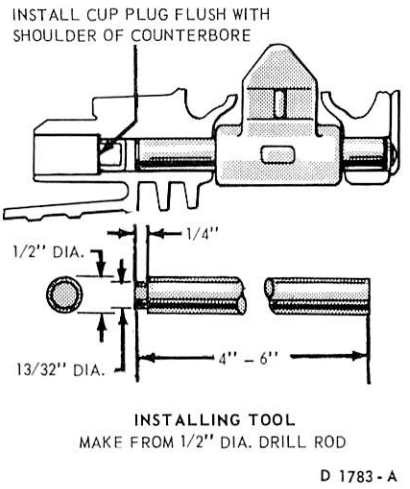

FIG. 29 Servo Apply Lever Installation

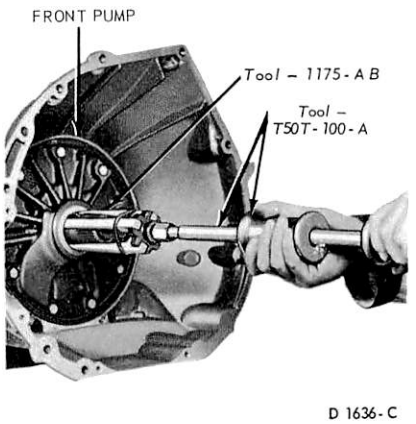

FIG. 30 Removing Front Pump Seal

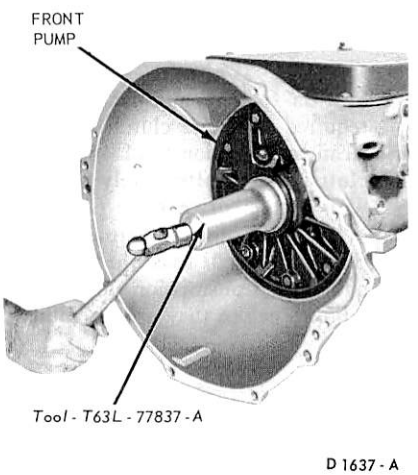

FIG. 31 Installing Fromt Pump Seal

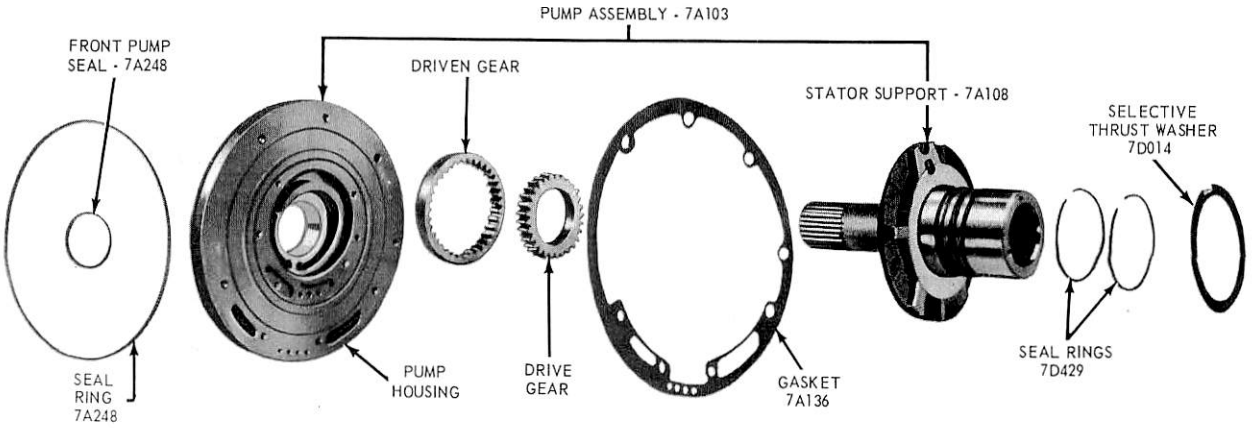

FIG. 32 Front Pump Disassembled

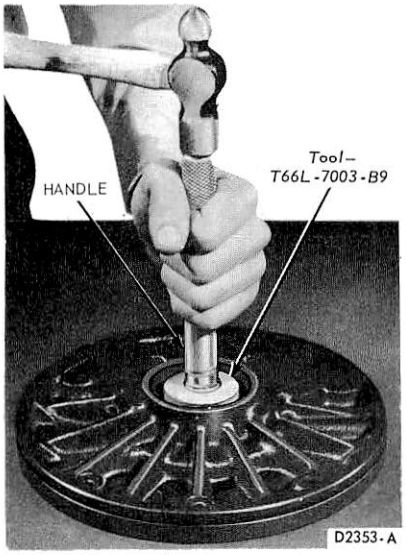

FIG. 33 Replacing Front Pump Housing Bushing

Section for the number of plates required. Dip the clutch plates in clean transmission fluid. Install the clutch plates alternately starting with a steel drive plate (Fig. 36). When new composition clutch plates are used, soak the plates in automatic transmission fluid for 15 minutes before they are assembled.

7. After all clutch plates have been installed, position the pressure plate in the clutch drum. Install the pressure plate snap ring.
8. With a feeler gauge, check the clearance between the pressure plate and snap ring (Fig. 42).
9. The pressure plate should be held downward as the clearance is checked. Refer to the Specification Section for the proper clearance. If the clearance is not within specifications, selective thickness snap rings are available in the following thicknesses: 0.056-0.060, 0.065-0.069, 0.074-0.078, 0.083-0.087 and 0.092-0.096 inch. Install the correct size snap ring and recheck the clearance.

FORWARD CLUTCH

Disassembly

1. Remove the clutch pressure plate retaining snap ring (Fig. 43).
2. Remove the rear pressure plate, the drive and driven plates and the forward pressure plate from the clutch hub (Fig. 44).
3. Remove the snap ring (Fig. 45) that secures the disc spring in the clutch cylinder. Remove the disc spring.
4. Apply air pressure to the clutch apply passage in the cylinder (Fig. 46) to remove the piston.
5. Remove the seal from the piston and the seal from the clutch hub (Fig. 44).

Assembly

1. Dip two new seals in transmission fluid. Install the smaller seal on the clutch hub and the other seal on the clutch piston.
2. Install the clutch piston in the cylinder.
3. Make sure that the steel pressure ring is in the groove on the piston. Position the disc spring in the cylinder with the dished face downward. Install the spring as shown in Fig. 45. Secure the disc with the retaining snap ring.
4. Install the forward pressure plate with the flat side up and the beveled side downward. Dip the clutch plates in clean transmission fluid. Install first a composition driven plate and a steel drive plate (Fig. 44). Install the remaining plates in this sequence. Refer to the Specification Section for the number of plates required. The last plate installed will be the rear pressure plate. Install the snap ring and make certain that it seats fully in the groove. When new composition clutch plates are used,

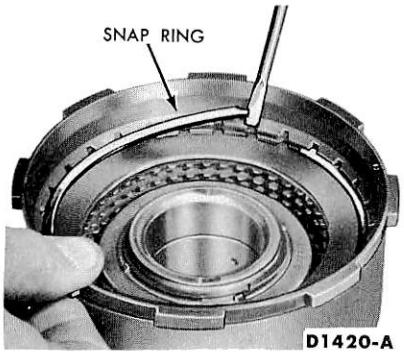

FIG. 35 Removing or Installing Reverse-High Clutch Pressure Plate Snap Ring

soak the plates in automatic transmission fluid for 15 minutes before they are assembled.

5. With a feeler gauge, check the clearance between the snap ring and the pressure plate (Fig. 47). Downward pressure on the plate should be maintained when making this check. Refer to the Specifications Section for the proper clearance.
6. If the clearance is not within specifications, selective snap rings are available in the following thicknesses: 0.056-0.060, 0.065-0.069, 0.074-0.078, 0.083-0.087 and 0.092-0.096 inch. Insert the correct size snap ring and recheck the clearance.

INPUT SHELL AND SUN GEAR

Disassembly

1. Remove the external snap ring from the sun gear as shown in Fig. 48.
2. Remove the thrust washer from the input shell and sun gear (Fig. 49).
3. Working from inside the input shell remove the sun gear. Remove the internal snap ring from the gear.

Assembly

1. Install the forward snap ring on the forward end (short end) of the sun gear (Fig. 46). Working from inside

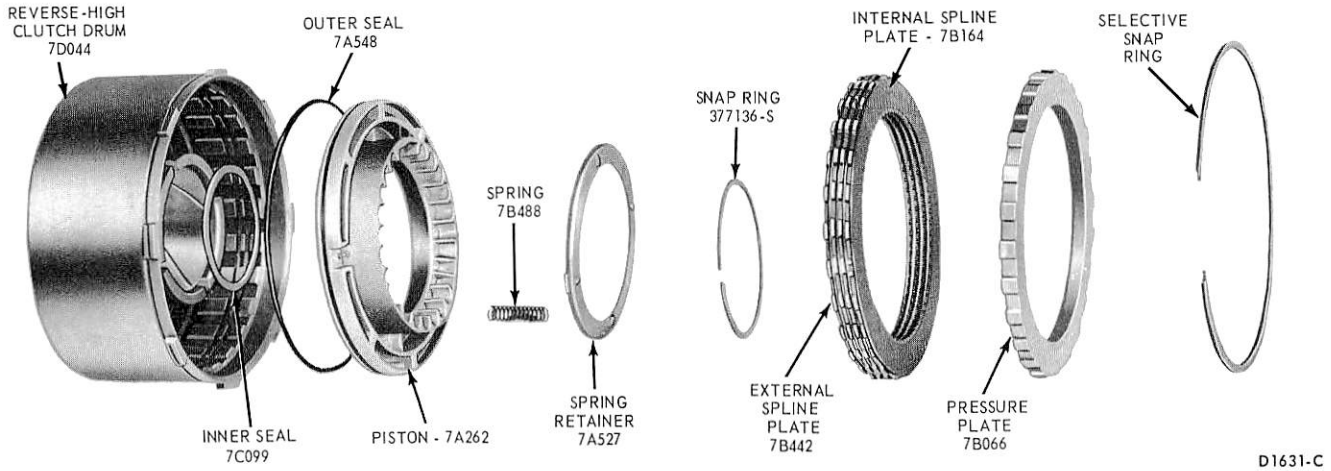

FIG. 36 Reverse-High Clutch Disassembled

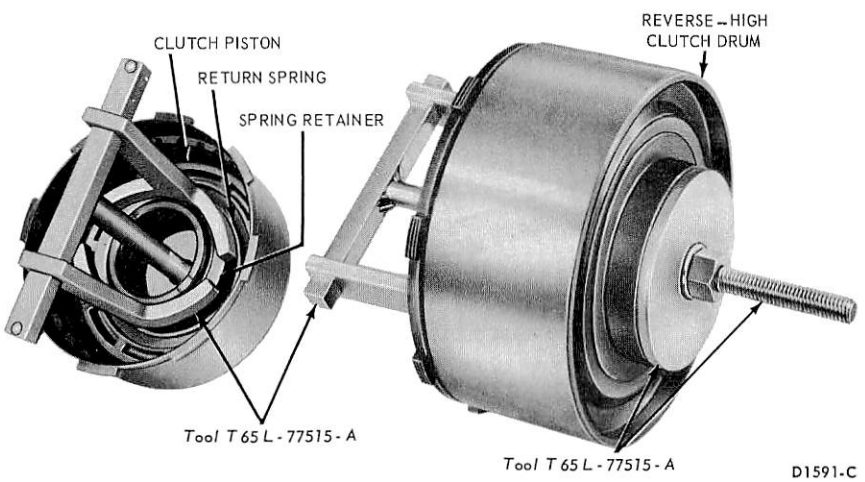

FIG. 37 Removing or Installing Reverse-High Clutch Piston Snap Ring

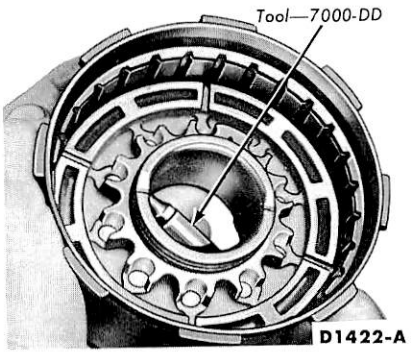

FIG. 38 Removing Reverse-High Clutch Piston

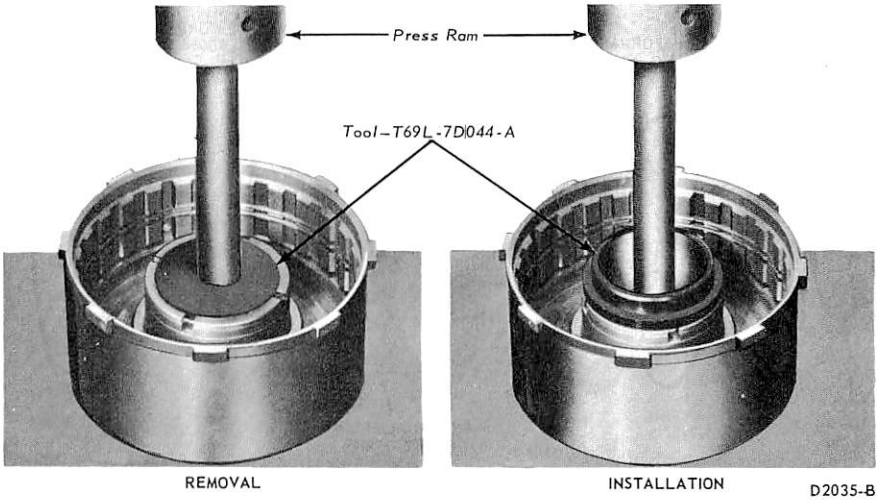

FIG. 39 Replacing Reverse-High Clutch Rear Bushing

the input shell, slide the sun gear and snap ring into place making sure that the longer end is at the rear (Fig. 49).
2. Place the No. 6 thrust washer on the sun gear and install the rear snap ring.

OUTPUT SHAFT HUB AND RING GEAR

Disassembly
1. Remove the hub retaining snap ring (Fig. 50) from the ring gear.
2. Lift the hub from the ring gear.

Assembly
1. Position the hub in the ring gear.
2. Secure the hub with the retaining snap ring. Make certain that the snap ring is fully engaged with the groove.

ONE-WAY CLUTCH

Disassembly
1. Remove the snap ring and bushing from the rear of the low-reverse clutch hub (Fig. 51).
2. Remove the rollers from the spring assembly and lift the spring assembly from the hub.
3. Remove the remaining snap ring from the hub.

Assembly
1. Install a snap ring in the forward snap ring groove of the low-reverse clutch hub.
2. Place the low-reverse clutch hub on the bench with the forward end down (Fig. 52).
3. Install the one-way clutch spring assembly on top of the snap ring.

4. Install a roller into each of the spring assembly compartments (Fig. 51).
5. Install the bushing on top of the spring assembly.
6. Install the remaining snap ring at the rear of the low-reverse clutch hub to secure the assembly (Fig. 51).

LOW-REVERSE CLUTCH PISTON

Disassembly

1. Remove the inner and the outer seal from the reverse clutch piston.

Assembly

1. Dip the two new seals in clean transmission fluid.
2. Install the seals on the piston.

DESCRIPTION

Figure 1 shows the location of the converter, front pump, clutches, bands, gear train and most of the internal parts used in the FMX transmission.

The identification tag (Fig. 2) on the FMX transmission is attached under the lower right hand extension-to-case bolt. The tag includes the model prefix, suffix build date code and serial number. The first line on the tag shows the transmission model prefix and suffix. A number appearing after the suffix (Fig. 2) indicates that the internal parts in the transmission have been changed after initial production start-up. For example, PHC-B model transmission that has been changed internally would read PHC-B1. Both transmissions are basically the same, but some service parts in the PHC-B1 transmission are slightly different that the PHC-B transmission. Therefore, it is important that the codes on the transmission identification tag be checked when ordering parts or making inquiries about the transmission.

The tag must be kept with the individual transmission it was originally installed on. If the tag was removed during disassembly, reinstall it on the same unit.

The FMX transmission is a three speed unit capable of providing automatic upshifts and downshifts through the three forward gear ratios, and also capable of providing manual selection of first and second gears.

The transmission consists essentially of a torque converter, planetary gear train, two multiple disc clutches and a hydraulic control system (Fig. 3).

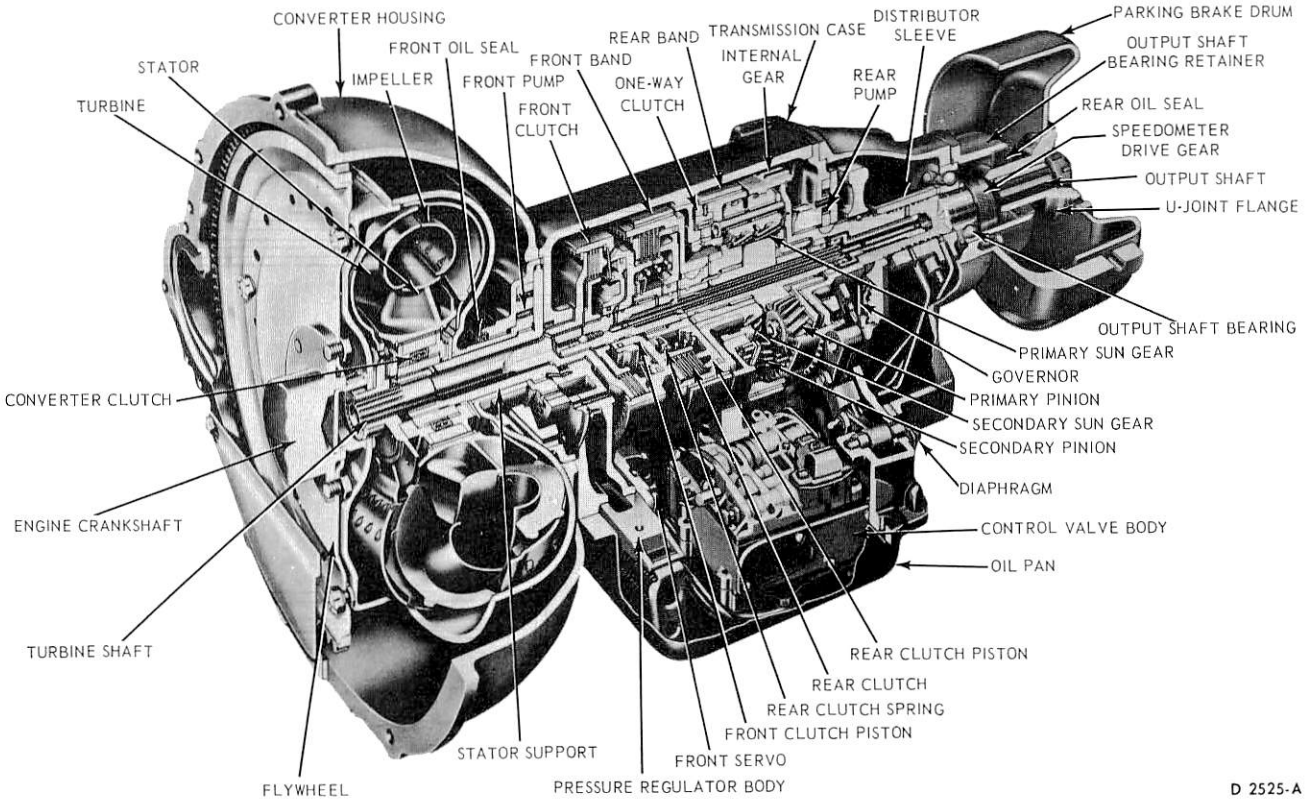

FIG. 1 FMX Transmission—Typical

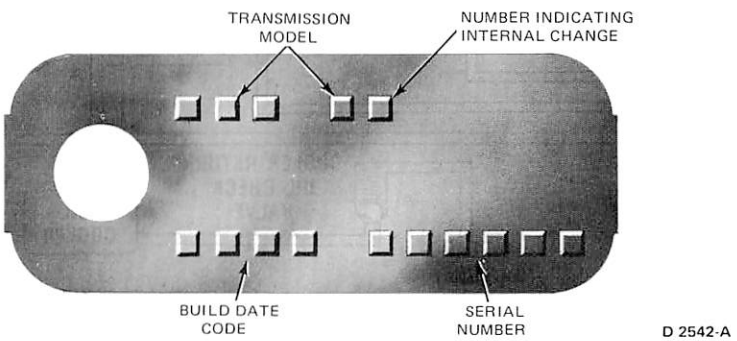

FIG. 2 Identification Tag

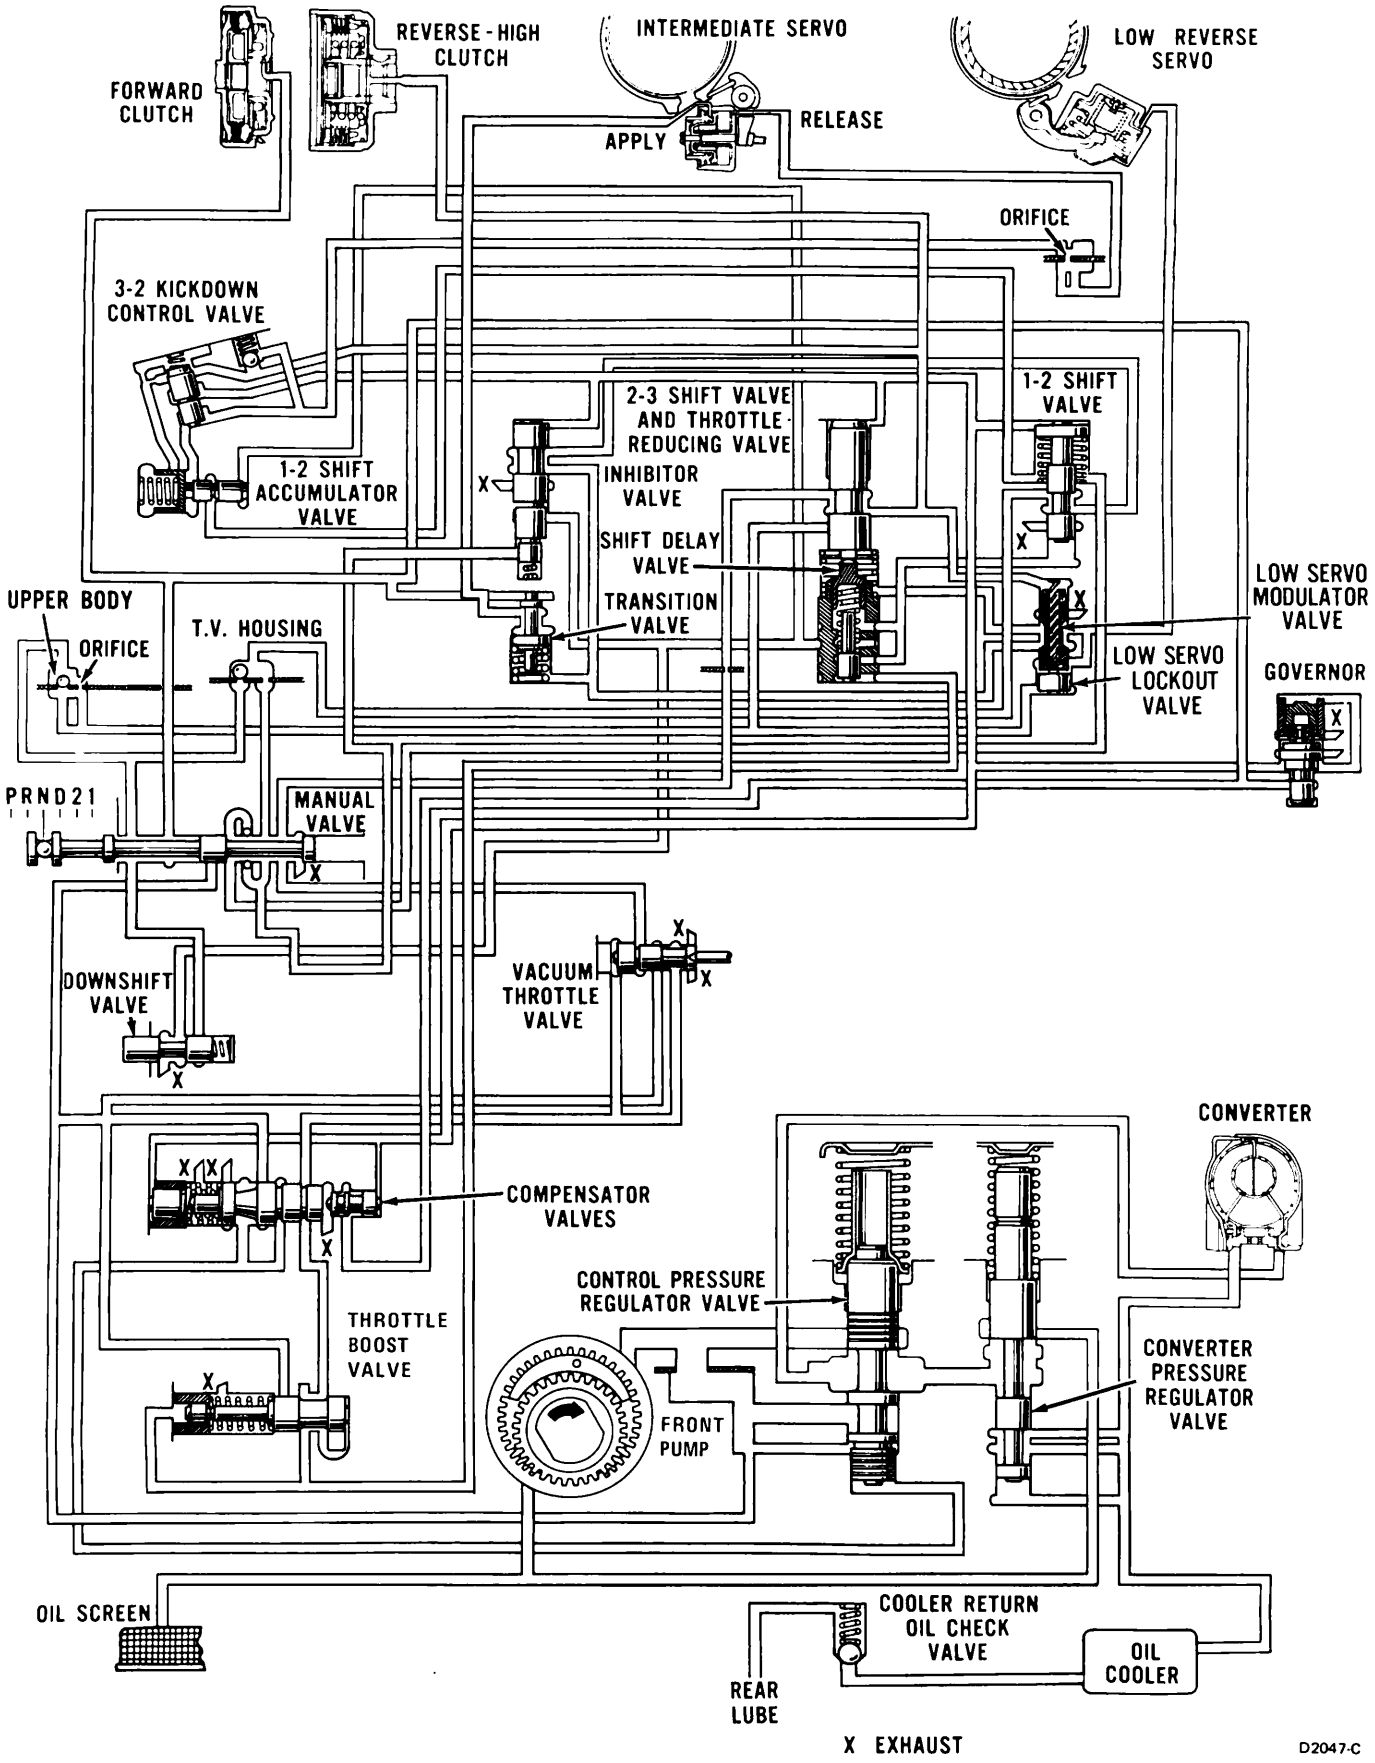

FIG. 3 Hydraulic Control System—FMX Transmission

ADJUSTMENTS

To prevent damage to the transmission and to assure proper band adjustment, it is essential that the tools and procedures described below are used whenever the bands are adjusted.

FRONT BAND ADJUSTMENT

1. Drain the fluid from the transmission by loosening the pan attaching bolts starting at the rear of the pan and working toward the front. When most of the fluid has drained from the pan, remove the remainder of the attaching bolts. Use a clean drain can equipped with a 100-mesh screen if the fluid is to be reused.
2. Remove the pan, then remove the fluid filter and clip from the transmission. Clean the inside of the pan. Remove all gasket material from the pan and pan mounting face of the case.
3. Loosen the front servo adjusting screw lock nut.
4. Pull back on the actuating rod, and insert the 1/4 inch spacer between the adjusting screw and servo piston stem (Fig. 4). Tighten the adjusting screw to 10 in-lbs torque. Remove the spacer and tighten the adjusting screw and additional 3/4 turn. Hold the adjusting screw stationary and tighten the lock nut securely.
5. Install the transmission fluid screen and clip. Install the pan using a new gasket.
6. Refill the transmission to the proper level with the specified fluid.

ALTERNATE FRONT BAND ADJUSTMENT

1. Drain the fluid from the transmission. If the same fluid is to be used again in the transmission after the band adjustment, filter the fluid through a 100-mesh screen as it drains from the transmission. Reuse the fluid only if it is in good condition.
2. Remove and thoroughly clean the pan and screen. Discard the pan gasket.
3. Loosen the front servo adjusting screw lock nut two full turns with a 9/16 inch wrench. Check the adjusting screw for free rotation in the actuating lever after the lock nut is loosened, and free the screw if necessary.
4. Pull the adjusting screw end of the actuating lever away from the servo body, and insert the 1/4 inch spacer (Fig. 5) between the servo piston stem and the adjusting screw.
5. Install the socket handle on the 9/16 inch socket.
6. Insert the T-handle extension through the socket handle and socket, and install the screwdriver socket on the T-handle extension.
7. Place the tool on the adjusting screw so that the screwdriver socket engages the screw and the 9/16 inch socket engages the lock nut.
8. With a torque wrench on the T-handle extension, tighten the adjusting screw to 10 in-lbs torque.
9. Remove the spacer and tighten the adjusting screw an additional 3/4 turn. Hold the adjusting screw stationary, and torque the lock nut to specification.
10. Place a new gasket on the pan, and install the screen and pan on the transmission.
11. Fill the transmission with fluid.

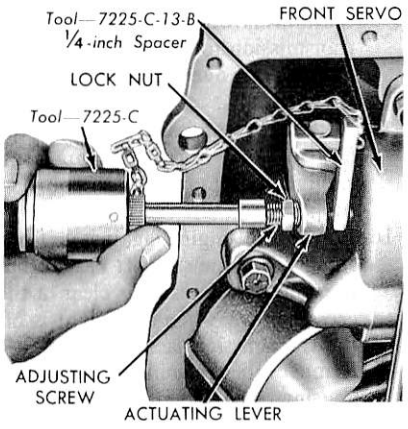

FIG. 4 Adjusting Front Band—Typical

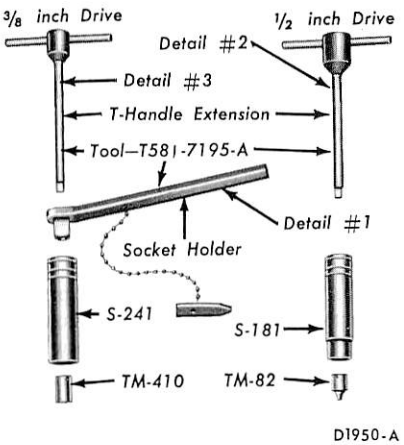

FIG. 5 Front Band Adjusting Tools

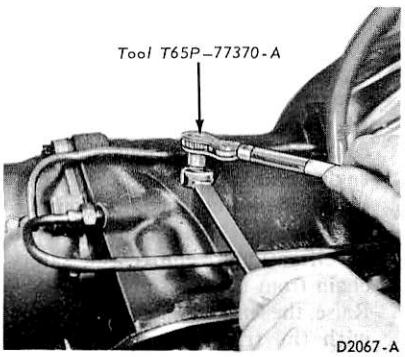

FIG. 6 Adjusting Rear Band

REAR BAND ADJUSTMENT

1. Remove all dirt from the adjusting screw threads, then oil the threads.
2. Loosen the rear band adjusting screw lock nut. Using the torque wrench shown in Fig. 6, tighten the adjusting screw until the tool handle clicks. The tool is a preset torque wrench which clicks and breaks when the torque on the adjusting screw reaches 10 ft-lbs.
3. If the screw is found to be tighter than wrench capacity (10 ft-lbs torque), loosen the screw and tighten until the wrench clicks and breaks.
4. Back off the adjusting screw 1-1/2 turns. Hold the adjusting screw stationary and tighten the adjusting screw lock nut to specification. **Severe damage may result if the adjusting screw is not backed off exactly 1-1/2 turns.**

REMOVAL AND INSTALLATION

TRANSMISSION AND CONVERTER

Removal

1. Drive the vehicle onto a hoist,**but do not raise it at this time.**
2. After removing the converter access hole covers, remove the two upper bolts and lock washers which attach the converter housing to the engine.
3. Raise the vehicle.
4. Place a drain pan under the transmission fluid pan. Starting at the rear of the pan and working toward the front, loosen the attaching bolts and allow the fluid to drain, finally remove all of the pan attaching bolts except two at the front, to allow the fluid to further drain. After the fluid has drained, install two bolts on the rear side of the pan to temporarily hold it in place.
5. Remove the converter drain plug access cover from the lower end of the converter housing.
6. Remove the converter-to-flywheel attaching nuts. Place a wrench on the crankshaft pulley attaching bolt to turn the converter to gain access to the nuts.
7. With the wrench on the crankshaft pulley attaching bolt, turn the converter to gain access to the converter drain plug. Then, remove the plug. Place a drain pan under the converter to catch the fluid. After the fluid has drained from the converter, reinstall the plug.
8. Wedge the converter to hold it in place when the transmission is removed.
9. Disconnect the starter cable from the starter, and disconnect the transmission to body ground cable from the transmission. Remove the starter.
10. On a transmission that has a oil cooler in the radiator, disconnect the fluid lines.

On models equipped with a side-mounted cooler, disconnect the radiator-to-cooler coolant lines at the cooler. Plug the lines to prevent coolant loss from the radiator.

11. Disconnect the manual and throttle linkages from the transmission.
12. Remove the vacuum hoses from the vacuum unit, remove the vacuum line retaining clips.
13. Disconnect the speedometer cable from the extension housing, and remove the drive shaft and/or coupling shaft.
14. Support the transmission on a transmission jack. Secure the transmission to the jack with safety chain. Remove both engine rear support bolts.
15. With the transmission jack, raise the engine and transmission high enough to remove the engine rear supports.
16. Lower the engine against a floor stand or engine support bar so that the converter housing is clear of the crossmember when all weight is off the transmission jack.
17. Remove the remaining converter housing-to-engine attaching bolts.
18. Move the assembly toward the rear and lower it, leaving the flywheel attached to the crankshaft. If additional clearance is needed, tilt the rear of the assembly upright slightly and to the rear (enough to allow removal of the six flywheel to crankshaft bolts). Move the assembly to the rear, and remove it.

Installation

1. Torque the converter drain plug to specification.
2. If the converter has been removed from the converter housing, carefully position the converter to the transmission making sure the converter drive flats are fully engaged in the pump gear. Install a wedge to prevent the converter from slipping out of the housing.
3. With the converter properly installed, place the transmission on the jack. Secure the transmission to the jack with safety chain.
4. Rotate the converter so that the studs and drain plug are in alignment with their holes in the flywheel.
5. Raise transmission and converter with the jack to align it with the engine. Remove the wedge from the converter housing. Carefully move the converter and transmission assembly forward into position, using care not to damage the flywheel and converter pilot.**The converter must rest squarely against the flywheel. This indicates that the converter pilot is not binding in the engine crankshaft.**
6. Install the lower converter housing-to-engine bolts. Torque the bolts to specification. Remove the safety chain from the transmission.
7. Raise the engine and transmission with the transmission jack, and remove the engine support stand or support bar.
8. Place the engine rear supports in a position on the crossmember.
9. Lower the engine and transmission against the supports, and at the same time install the support bolts.
10. Install and torque the four converter-to-flywheel attaching nuts to specification. Install the converter housing access cover and secure it with the attaching bolts.
11. Connect the oil cooler inlet and outlet lines to the transmission or side-mounted cooler.
12. Install the vacuum lines and retaining clips. Install the vacuum hoses on the vacuum unit.
13. Coat the universal joint knuckle with transmission fluid, and install the drive shaft and/or coupling shaft.
14. Connect the speedometer cable to the transmission.
15. Connect the manual linkage rod to the transmission manual lever.
16. Connect the throttle linkage to the transmission throttle lever.
17. Install the linkage splash shield.
18. Install the starter motor. Connect the transmission to frame ground cable.
19. Connect the fluid filler tube.
20. Lower the hoist. Then install the upper two converter housing-to-engine bolts and torque to specification.
21. Install the access hole covers, and position the floor mat.
22. Fill the transmission with fluid to the specified level.
23. Check the transmission, converter assembly, and oil cooler lines for fluid leaks. Then adjust the transmission control linkage.

CONTROL VALVE BODY

Removal

1. Raise the vehicle so that the transmission fluid pan is accessible.
2. Drain the fluid from the transmission by loosening the pan attaching bolts starting at the rear of the pan and working toward the front. When most of the fluid has drained from the pan, remove the remainder of the attaching bolts. Remove the pan and gasket. Discard the gasket.**If the same fluid is to be used again in the transmission, filter the fluid through a 100-mesh screen as it drains from the transmission. Re-use the fluid only if it is in good condition.**

3. Remove the fluid screen retaining clip and the screen.
4. Disconnect the hoses from the vacuum diaphragm unit. Remove the diaphragm unit using Snap-On Tool S8696-A.**Do not use any tools on the diaphragm housing, such as pliers, pipe wrenches, etc. Do not allow solvents to enter the diaphragm unit. Remove the push rod.**
5. Remove the small compensator pressure tube (Fig. 7).
6. Remove the main pressure oil tube first, by gently prying up the end that connects to the main control valve assembly, then, remove the other end of the tube from the pressure regulator.**Be sure to remove the tube in this manner. Failure to do so, could kink or bend the tube causing excessive transmission internal leakage.**
7. Loosen the front servo attaching bolts three turns.
8. Remove the three control valve body attaching bolts, and lower the valve body while pulling it off the front servo tube.**Be careful not to damage the valve body or the tubes.**

Installation

1. Before installing the control valve body, check for a bent manual valve by rolling it on a flat surface.
2. Install the control valve body by aligning the front servo tubes with the holes in the valve body. Shift the manual lever to the 1 detent, and place the inner downshift lever between the downshift lever stop and the downshift valve.**The manual valve must engage the actuating pin in the manual detent lever.**
3. Install but do not tighten, the control valve body attaching bolts.
4. Move the control valve body toward the center of the case until the clearance is less than 0.050 inch, between the manual valve and the actuating pin on the manual detent lever.
5. Torque the attaching bolts to specification. Be sure that the rear fluid screen retaining clip is installed under the valve body bolt as shown in Fig. 7.
6. Install the main pressure oil tube.**Be sure to install the end of the tube that connects to the pressure regulator first. Then, install the other end of the tube into the main control valve assembly by tapping it gently with a soft hammer.**
7. Install the compensator pressure tube to the pressure regulator and the control valve body.

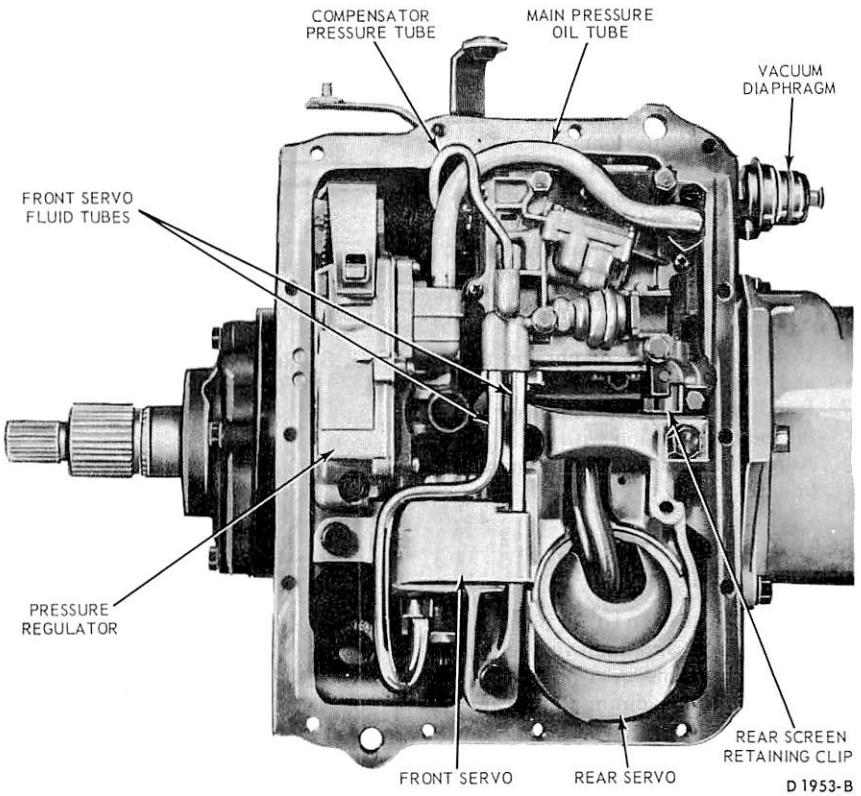

FIG. 7 Typical Hydraulic Control System

8. Turn the manual valve one full turn in each manual lever detent position. If the manual valve binds against the actuating pin in any detent position, loosen the valve body attaching bolts and move the body away from the center of the case. Move the valve body only enough to relieve the binding. Torque the attaching bolts and recheck the manual valve for binding.
9. Position the push rod in the bore of the vacuum diaphragm unit. Using the diaphragm unit as a guide, insert the push rod into the threaded opening of the case. Torque the diaphragm unit to specification. Connect the vacuum hose.
10. Torque the front servo attaching bolts to specification.
11. Adjust the front band.
12. Install the fluid screen and the screen retaining clip.
13. Position a new pan gasket on the bottom of the transmission case, and install the pan. Torque the pan screws to specification.
14. Adjust the rear band.
15. Fill the transmission to the proper level with the specified fluid.**If the fluid that was drained from the transmission is to be used again, filter the fluid through a 100-mesh screen as it is poured back into the transmission. Re-use the fluid only if is in good condition.**
16. If the control valve body was replaced, adjust the transmission control linkage.

FRONT SERVO

Removal

1. Drain the fluid from the transmission, and remove the pan and fluid screen.
2. Remove the vacuum diaphragm unit.
3. Loosen the three control valve body attaching bolts.
4. Remove the attaching bolts from the front servo (Fig. 7), hold the strut with the fingers, and remove the servo.

Installation

1. To install the front servo, position the front band forward in the case with the end of the band facing downward. Make sure the front servo anchor pin is in position in the case web. Align the large end of the servo strut with the servo actuating lever, and align the small end with the band end.

2. Rotate the band, strut, and servo to align the anchor end of the band with the anchor in the case.

Push the servo body onto the control valve body tubes.

3. Install the attaching bolts and torque to specification.
4. Torque the control valve body attaching bolts to specification.

Check the clearance between the manual valve and manual lever actuating pin as given in Control Valve Body Removal and Installation.

5. Adjust the front band.
6. Install the vacuum diaphragm unit and rod.
7. Install the fluid screen and pan, and fill the transmission with fluid.
8. Adjust the downshift and manual linkage.

REAR SERVO

Removal

1. Drain the fluid from the transmission and remove the pan and fluid screen.
2. Remove the vacuum diaphragm unit.
3. Remove the control valve body and the two front servo tubes.
4. Remove the attaching bolts from the rear servo, hold the actuating and anchor struts with the fingers, and remove the servo.

Installation

1. To install the rear servo, position the servo anchor strut on the servo band, and rotate the band to engage the strut.
2. Hold the servo anchor strut in position with the fingers, position the actuating lever strut, and install the servo.
3. Install but do not tighten the servo attaching bolts. **The longer bolt must be installed in the inner bolt hole.**
4. Move the rear servo (with reasonable force) toward the centerline of the transmission case, against the servo attaching bolts. While holding the servo in this position, torque the attaching bolts to specification.
5. Install the two front servo tubes and the control valve body.

Check the clearance between the manual valve and the manual lever actuating pin as given in Control Valve Body Removal and Installation.

6. Adjust the rear band.
7. Install the fluid screen and pan, and fill the transmission with fluid.

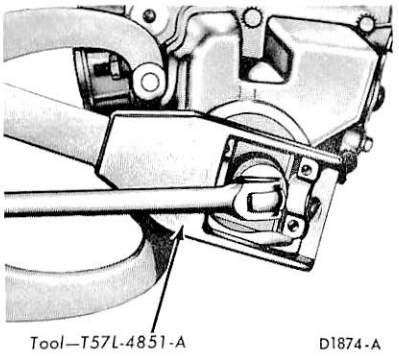

FIG. 8 Removing Companion Flange

FIG. 9 Removing Extension Housing Bearing Snap Ring

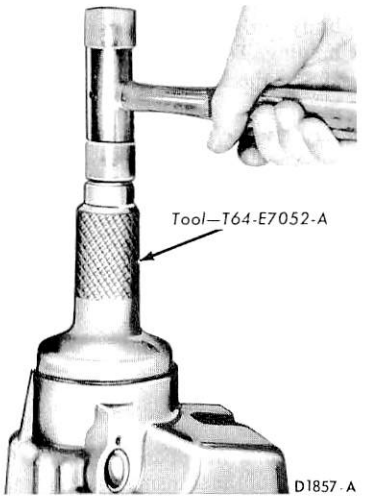

FIG. 10 Installing Extension Housing Seal

EXTENSION HOUSING REAR SEAL AND/OR BEARING

Removal

1. Raise the vehicle and remove the drive shaft. Remove the parking brake drum, if so equipped. Remove the transmission output shaft yoke attaching nut and yoke with the tools shown in Fig. 8
2. With a sharp chisel, remove the seal from the extension housing. Do not allow metal chips to enter the output shaft bearing.
3. To remove the output shaft bearing from the extension housing, remove the bearing retaining snap ring (Fig. 9).
4. Remove the bearing from the extension housing. Install a new bearing.

Installation

1. Install the bearing retaining snap ring. Make sure the snap ring is fully seated in the ring groove of the housing.
2. Install a new extension housing seal using the tool shown in Fig. 10. Install the output shaft yoke and retaining nut. Torque the attaching nut to specifications. Install the parking brake drum, if so equipped.
3. Install the drive shaft and torque the attaching bolts to specification.
4. Lower the vehicle and check the transmission fluid level.

GOVERNOR

Removal

1. Raise the vehicle so that the transmission extension housing is accessible.
2. Remove the governor inspection cover from the extension housing.
3. Rotate the drive shaft until the governor is in line with the inspection hole (Fig. 11).
4. Remove the governor valve body from the counterweight. Do not drop the attaching bolts or the valve parts into the extension housing.

Installation

1. Lubricate the new governor valve parts with transmission fluid. **The valve must move freely in the valve body bore.**
2. Install the governor body on the counterweight so that the valve body cover is facing rearward. Tighten the two attaching bolts securely.
3. Install the governor inspection cover

and a new gasket on the extension housing. Torque the attaching screws to specifications.

PRESSURE REGULATOR

Removal

1. Drain the fluid from the transmission, and remove the pan and fluid screen.
2. Remove the small compensator pressure tube from the control valve body and the pressure regulator (Fig. 7).
3. Remove the main pressure oil tube first, by gently prying up the end that connects to the main control valve assembly, then, remove the other end of the tube from the pressure regulator (Fig. 7).**Besure to remove the tube in this manner. Failure to do so, could kink or bend the tube causing excessive transmission internal leakage.**
4. Remove the pressure regulator spring retainer, springs, and spacer.

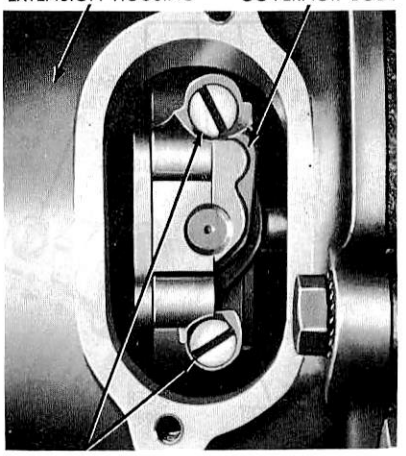

FIG. 11 Governor in Extension Housing

Maintain pressure on the retainer to prevent the springs from flying out.

5. Remove the pressure regulator attaching bolts and washers, and remove the regulator.

Installation

1. Position the replacement regulator body on the transmission case and install the two attaching bolts. Torque the bolts to specification.
2. Check the converter pressure and control pressure valves to be sure the valves operate freely in the bores.
3. Install the valve springs, spacer and retainer.
4. Install the main pressure oil tube.**Be sure to install the end of the tube that connects to the pressure regulator assembly first. Then, install the other end of the tube into the main control assembly by tapping it gently with a soft hammer.**
5. Install the small compensator pressure tube.
6. Install the fluid screen and the pan, and fill the transmission to the correct level with the specified fluid.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

During the repair of the subassemblies, certain general instructions which apply to all units of the transmission must be followed. These instructions are given here to avoid unnecessary repetition.

Handle all transmission parts carefully to avoid nicking or burring the bearing or mating surfaces.

Lubricate all internal parts of the transmission with the transmission fluid before assembly.**Do not use any other lubricants except on gaskets and thrust washers which may be coated with vaseline to facilitate assembly. Always install new gaskets when assembling parts of the transmission.**

Tighten all bolts and screws to the recommended torque. For detail cleaning and inspection operations refer to Part 17-01.

Disassembly

1. Before removing any of the transmission sub-assemblies, thoroughly clean the outside of the transmission case to prevent dirt from getting inside the mechanism.
2. After the transmission has been removed from the vehicle, disconnect the oil cooler lines at the transmission. Remove the cooler bracket mounting bolts at the transmission and place the assembly in the transmission holder Tool 7000-CJ.
3. Remove the transmission pan, gasket, and screen retainer clip.
4. Lift the screen from the case.
5. Remove the spring seat from the pressure regulator.**Maintain constant pressure on the seat to prevent distortion of the spring seat and the sudden release of the springs.**Remove the pressure regulator springs and pilots, but do not remove valves.
6. Remove the small compensator pressure tube from the pressure regulator and the control valve body.
7. Remove the main pressure oil tube first, by gently prying up the end that connects to the main control valve assembly, then, remove the other end of the tube from the pressure regulator.**Besure to remove the tube in this manner. Failure to do so, could kink or bend the tube causing excessive transmission internal leakage.**
8. Loosen the front and rear servo band adjusting screws five turns. Loosen the front servo attaching bolts three turns.
9. Remove the vacuum diaphragm unit and push rod.
10. Remove the control valve body attaching bolts. Align the levers to permit removal of the valve body. Then lift the valve body clear of the transmission case. Pull the body off the servo tubes and remove it from the case.
11. Remove the regulator from the case. **Keep the control pressure valve and the converter pressure regulator valve in the pressure regulator to avoid damage to the valves.**
12. Remove the front servo apply and release tubes by twisting and pulling at the same time. Remove the front servo attaching bolts. Hold the front servo strut with the fingers, and lift the servo assembly from the case.
13. Remove the rear servo attaching bolts. Hold the actuating and anchor struts with the fingers, and lift the servo from the case.

Transmission End Play Check

1. Remove one of the front pump attaching bolts. Mount the dial indicator support Tool 77067 in the front pump bolt hole. Mount a dial indicator on the support so that the contact rests on the end of the turbine shaft.
2. Pry the output shaft all the way forward by using a screwdriver between the large internal gear and the case.

3. Lightly block the output shaft in the forward position to eliminate all output shaft end play.
4. Move the pinion carrier all the way forward by inserting a screwdriver between the planet carrier and the large internal gear and prying against the case. Maintain slight forward pressure, and set the dial indicator at zero.
5. Measure and record the end play between the front of the case and the large internal gear by prying between the front clutch cylinder and the case. This end play should be 0.010-0.029 inch. Total end play including output shaft end play must not exceed 0.044 inch.

Removal Of Case And Extension Housing Parts

1. Remove the remaining front pump attaching bolts. Then remove the front pump and gasket.

If necessary, tap the screw bosses with soft-faced hammer to loosen the pump from the case. **If the parking brake drum (Fig. 12) is mounted on the transmission, remove the drum and yoke from the output shaft.**

2. Remove the extension housing seal. Remove the lubrication tube from the case. Remove the five transmission to extension housing bolts. These bolts also attach the rear support to the case. Remove the extension housing.
3. Remove the output shaft assembly (Fig. 13). Be careful not to bend the pressure tubes between the distributor sleeve and case as the tubes are removed from the case.
4. Place the output shaft assembly on the bench and remove the oil distributor tubes from the sleeve.
5. Slide the speedometer drive gear off the shaft.
6. If the drive gear ball does not fall out as the speedometer gear is removed, remove the ball from the seat in the output shaft.
7. Remove the distributor sleeve. Remove the four seal rings from the output shaft with the fingers to prevent breaking the rings.
8. Remove the governor snap ring from the output shaft. Slide the governor assembly off the output shaft. Then remove the governor drive ball. Remove the rear pump, extension housing and pump gaskets.
9. Remove the rear pump drive key from the output shaft. Then remove the bronze thrust washer from the output shaft.
10. Remove the selective thrust washer from the rear of the pinion carrier.

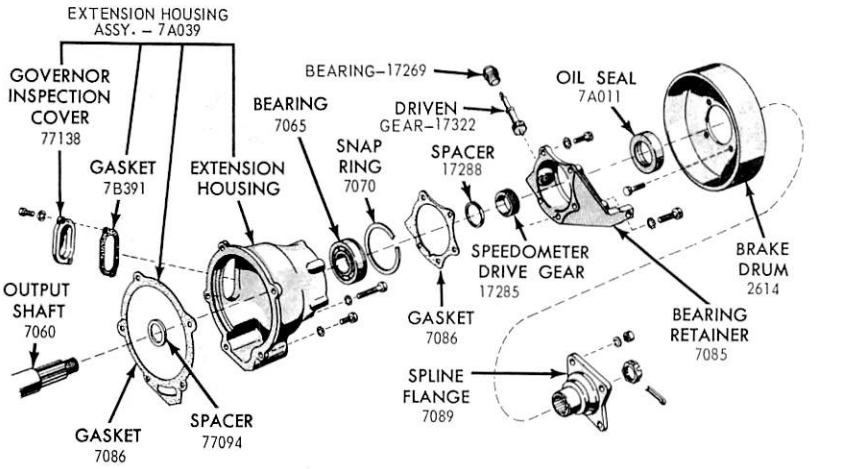

FIG. 12 Parking Brake Drum and Extension Housing Components

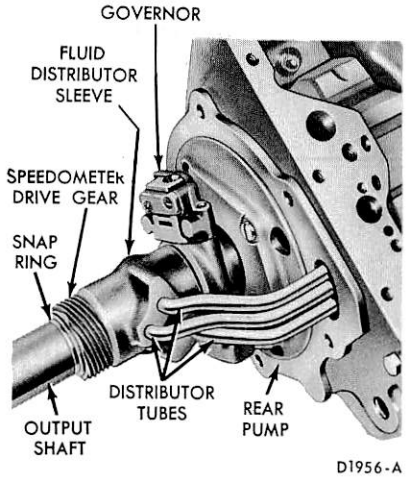

FIG. 13 Output Shaft and Rear Pump Installed

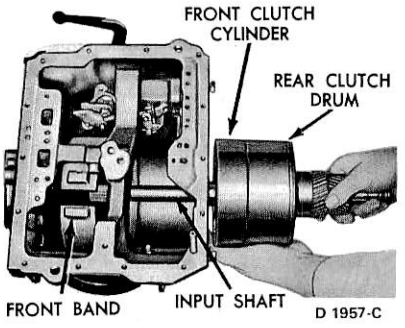

FIG. 14 Removing or Installing Input Shaft and Clutch

11. Remove the two seal rings from the primary sun gear shaft. Remove the pinion carrier.
12. Remove the primary sun gear rear thrust bearing and race from the pinion carrier.
13. Note the rear band position for reference in assembly. The end of the band next to the adjusting screw has a depression (dimple) in the center of the boss. Squeeze the ends of the rear band together, tilt the band to the rear, and remove the rear band from the case.
14. Remove the two center support outer bolts (one each side) from the transmission case.
15. Exert enough pressure on the end of the input shaft to hold the clutch units together. Then remove the center support and the front and rear clutch assemblies as a unit (Fig. 14).
16. Install the clutch assemblies in the bench fixture (Fig. 15).
17. Remove the thrust washer from the front of the input shaft.
18. To remove the front band, position the band ends between the case webbing and tilt the bottom of the band rearward. Then, squeeze the ends of the band together and remove from the rear of the case.
19. Lift the front clutch assembly from the primary sun gear shaft.
20. Remove the bronze and the steel thrust washers from the rear clutch assembly, wire the thrust washers together to assure correct installation.
21. Remove the front clutch seal rings from the primary sun gear shaft.
22. Lift the rear clutch assembly from the primary sun gear shaft.
23. Remove the rear clutch seal rings from the primary sun gear shaft. **Do not break the seal rings.**
24. Remove the primary sun gear front thrust washer.
25. **If the transmission case bushing is to be replaced, press the bushing out**

of the case with the tools shown in Fig. 16.

26. Install a new transmission case bushing with the tool shown in Fig. 16.
27. If the rear brake drum support bushing is to be replaced, press the bushing from the support as shown in Fig. 17.
28. Press a new bushing into the brake drum support with the tool shown in Fig. 17.
29. Remove the output shaft bushing if it is worn or damaged. Use the cape chisel and cut along the bushing seam until the chisel breaks through the bushing wall. Pry the loose ends of the bushing up with an awl and remove the bushing.
30. Insert a new bushing into the installation tool and position the tool and bushing over the output shaft hub. Then, press the bushing on the output shaft hub as shown in Fig. 18.

Assembly

Do not use force to assemble mating parts. If the parts do not assemble freely, examine them for the cause of the difficulty.**Always use new gaskets and seals during the assembly operations.**

1. Install the front band in the transmission case so that the anchor end is aligned with the anchor in the case.
2. Make sure the thrust washer is in place on the input shaft. Lift the clutch assemblies out of the holding block.

Do not allow the clutches to separate.

3. Install the clutch sub-assemblies in the transmission case while positioning the servo band on the drum. Hold the units together while installing them (Fig. 14).

Installation—Center Support

a. Install the center support and the rear band in the case.
b. Install the primary sun gear rear thrust bearing race, needle bearing, and front thrust bearing race in the planet carrier using petroleum jelly to retain them in place.
c. Lubricate the bearing surface on the center support, the rollers of the planetary clutch, and the cam race in the carrier with petroleum jelly (Fig 19).
d. Install the planetary clutch in the carrier (Fig. 20).
e. Carefully position the planet carrier on the center support. Move the carrier forward until the clutch rollers are felt to contact the bearing surface of the center support.
f. While applying forward pressure on the planet carrier, rotate it counterclockwise, as viewed from the rear (Fig. 20). This will cause the clutch rollers to roll toward the large opening end of the cams in the race, compressing the spring slightly, so that the rollers will ride up the chamfer on the planetary support and onto the inner race.
g. Push the planet carrier all the way forward.
h. Check the operation of the planetary clutch by rotating the carrier counterclockwise. It

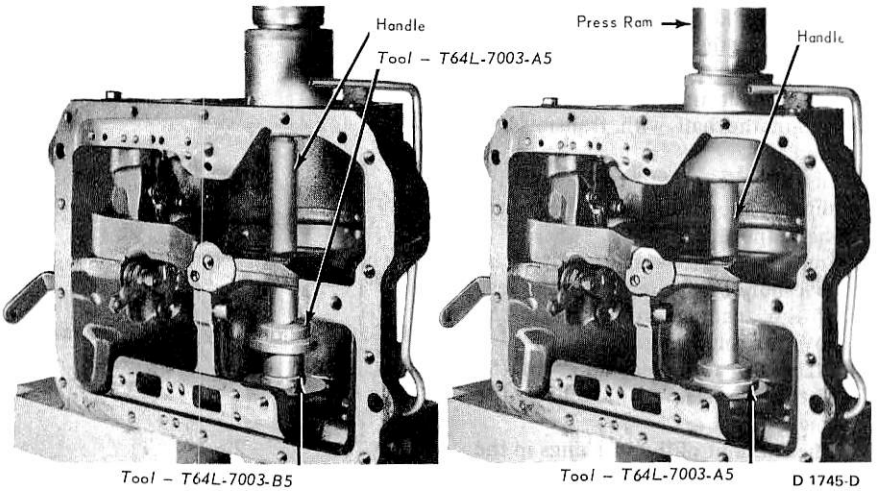

FIG. 16 Replacing Transmission Case Bushing

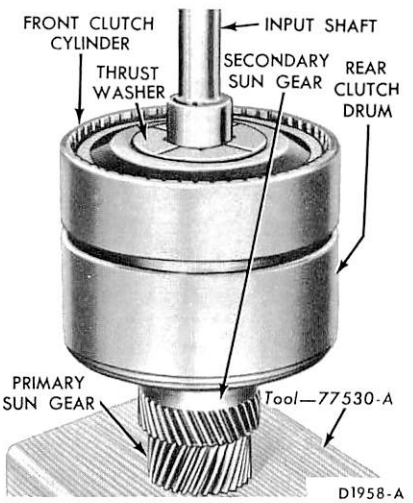

FIG. 15 Input Shaft and Clutch Mounted in Holding Fixture

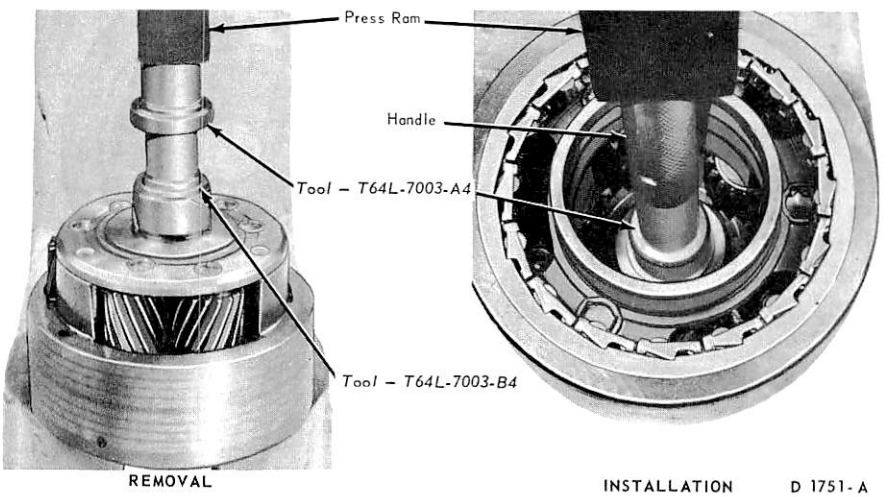

FIG. 17 Replacing Rear Brake Drum Support Bushing

should rotate counterclockwise (viewed from the rear) with a slight drag, and it should lock up when attempting to rotate it in a clockwise direction.

i. Install the selective thrust washer on the pinion carrier rear pilot. **If the end play was not within specifications when checked prior to disassembly, replace the washer with one of proper thickness.** Refer to the Specification Section for selective thrust washer thicknesses.

j. Install the output shaft, carefully meshing the internal gear with the pinions.

4. With the center support properly assembled, position the rear pump drive key in the keyway on the output shaft.
5. Position new front and rear gaskets on the pump body. Retain the gaskets with transmission fluid. Then install the rear pump. **Be sure the drive key is aligned with the keyway in the pump drive gear.**
6. Position the governor drive ball in the pocket in the output shaft. Retain the ball with transmission fluid.
7. Install the governor assembly, aligning the groove with the ball in the output shaft.
8. **Install the governor with the governor body plate toward the rear of the transmission.** Install the governor snap ring.
9. Place the four seal rings in the distributor sleeve, and check the ring gap.
10. Check the fit of the seal rings in the grooves in the output shaft. The rings should rotate freely. Install the rings in the grooves of the output shaft.
11. Install the three tubes in the distrubutor sleeve.
12. Install the distributor sleeve on the output shaft, with the chamfer facing forward. Lubricate the parts to facilitate assembly. Slide the sleeve over the four rings and at the same time start the tubes into the case. The distributor sleeve is located between the governor snap ring and speedometer drive gear.
13. Make sure that the speedometer drive gear lock ball is in place, then install the gear.
14. Install the output shaft ball bearing front spacer and the output shaft ball bearing with the snap ring toward the rear.
15. Install the output shaft rear spacer and the speedometer drive gear.
16. Install the rear bearing retainer gasket and the retainer. Torque the bolts to specification.
17. Install the brake drum if so equipped and/or the U-joint yoke. Torque the nut to specification. Tighten the nut to the nearest cotter pin hole, and install the cotter pin.
18. Position a new front pump gasket in the counterbore of the transmission case.
19. Install the front pump, aligning the

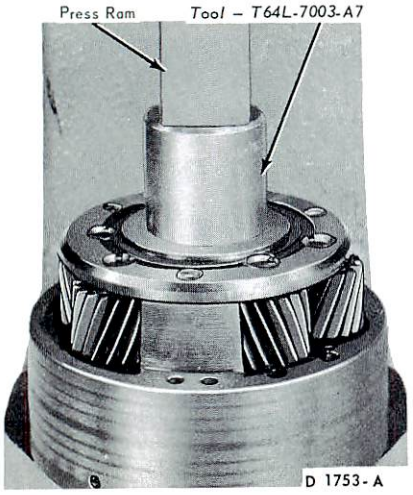

FIG. 18 Installing Output Shaft Bushing

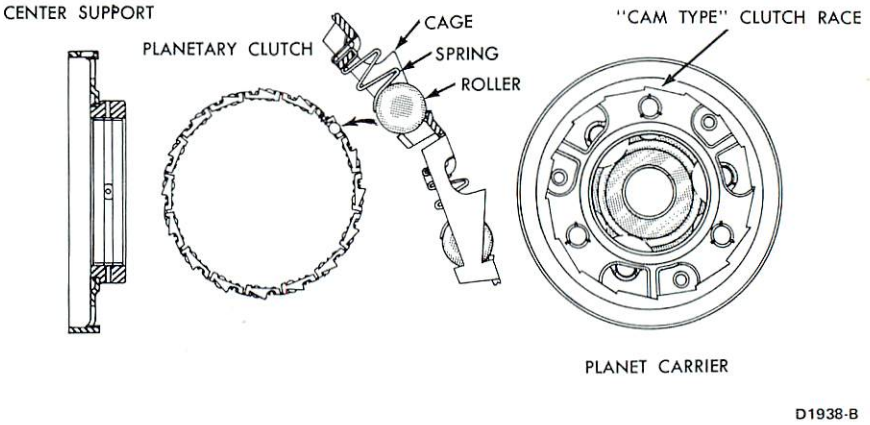

FIG. 19 Planetary Clutch, Planet Carrier and Center Support

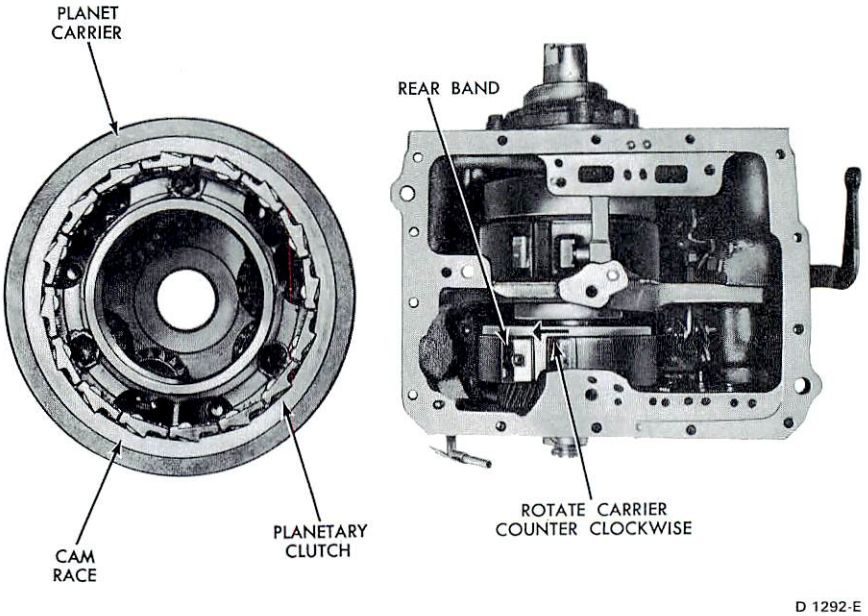

FIG. 20 Planetary Clutch Installation in Carrier

pump bolt holes with the holes in the case. Install three of the front pump attaching bolts and torque them to specification.

20. Mount dial indicator support in a front pump bolt hole. Mount a dial indicator on the support so that the contact rests on the end of turbine shaft.
21. Pry the output shaft all the way forward by using a screwdriver between the large internal gear and the case.
22. Lightly block the output shaft in the forward position to eliminate all output shaft end play.
23. Move the pinion carrier all the way forward by inserting a screwdriver between the planet carrier and the large internal gear and prying against the case. Maintain slight forward pressure, and set the dial indicator at zero.
24. Measure and record the end play between the front of the case and the large internal gear by prying between the front clutch cylinder the the case. This end play should be 0.010-0.029 inch. Total end play including the output shaft, must not exceed 0.044 inch.
25. Remove the dial indicator and install the fourth pump mounting bolt. Torque all four bolts to specification.
26. Position the front band forward in the case with the band ends up.
27. Position the servo strut with the slotted end aligned with the servo actuating lever, and the small end aligned with the band end. Rotate the band, strut, and servo into position engaging the anchor end of the band with the anchor pin in the case.
28. Locate the servo on the case, and install the attaching bolts**Tighten the attaching bolts only 2 or 3 threads.**
29. Install the servo tubes.
30. Position the servo anchor strut, and rotate the rear band to engage the strut.
31. Position the servo actuating lever strut with a finger, and then install the servo and attaching bolts. Move the servo (with reasonable force) toward the centerline of the case, against the attaching bolts. While holding the servo in this position, torque the attaching bolts to specification.
32. Install the pressure regulator body and attaching bolts, and torque the bolts to specifications.
33. Install the control and converter valve guides and springs. Install the spring retainer.
34. Install the control valve assembly, carefully aligning the servo tubes with the control valve. Align the inner downshaft lever between the stop and the downshift valve. Shift the manual lever to the 1 position. **Align the manual valve with the actuating pin in the manual detent lever. Do not tighten the attaching bolts.**
35. Install the main pressure oil tube.**Be sure to install the end of the tube that connects to the pressure regulator assembly first. Then, install the other end of the tube into the main control assembly by tapping it gently with a soft hammer.**
36. Install the small control pressure compensator tube in the valve body and regulator.
37. Move the control valve body toward the center of the case until the clearance is less than 0.050 inch between the manual valve and the actuating pin on the manual detent lever.
38. Torque the attaching bolts to specification. Be sure that the rear fluid screen retaining clip is installed under the valve body bolt as shown in Fig. 7.
39. Turn the manual valve one full turn in each manual lever detent position. If the manual valve binds against the actuating pin in any detent position, loosen the valve body attaching bolts and move the body away from the center of the case. Move the body only enough to relieve the binding. Torque the attaching bolts and check the manual valve for binding.
40. Torque the front servo attaching bolts to specification.
41. Adjust the front and rear bands as detailed in Adjustments.
42. Position the control rod in the bore of the vacuum diaphragm unit and install the diaphragm unit. Make sure the control rod enters the throttle valve as the vacuum unit is installed.
43. Torque the diaphragm unit to specification.
44. Position the fluid screen under the rear clip and over the front pump inlet tube. Press the screen down firmly. Install the screen retaining clip.
45. Place a new gasket on the transmission case and install the pan. Install the attaching bolts and lock washers and torque the bolts to specifications.

If the converter and converter housing were removed from the transmission, install these components. Position the transmission assembly on the transmission jack, and refer to Transmission Installation Procedures for installing the transmission.

CONTROL VALVE BODY

During the disassembly of the control valve assembly, avoid damage to valve parts and keep the valve parts clean. Place the valve assembly on a clean shop towel while performing the disassembly operation.**Do not separate the upper and lower valve bodies and cover until after the valves have been removed.**

Disassembly

1. Remove the manual valve (Fig. 21).
2. Remove the throttle valve body and the separator plate. Be careful not to lose the check valve when removing the separator plate from the valve body. Remove the throttle valve and plug.
3. Remove one screw attaching the separator plate to the lower valve body. Remove the upper body front plate.**The plate is spring-loaded. Apply pressure to the plate while removing the attaching screws.**
4. Remove the compensator sleeve and plug, and remove the compensator valve springs. Remove the compensator valve.
5. Remove the throttle boost short valve and sleeve. Remove the throttle boost valve spring and valve.
6. Remove the downshift valve and spring.
7. Remove the upper valve body rear plate.
8. Remove the compensator cut back valve.
9. Remove the lower body side plate (Fig. 21).**The plate is spring-loaded. Apply pressure to the plate while removing the attaching screws.**
10. Remove the 1-2 shift valve and spring. Remove the inhibitor valve and spring.
11. Remove the two screws attaching the separator plate to the cover. Remove the lower body end plate. **The end plate is spring-loaded. Apply pressure to the plate while removing the attaching screws.**
12. Remove the low servo lockout valve, low servo modulator valve and spring.
13. Remove the 2-3 delay and throttle reducing valve sleeve, the throttle reducing valve, spring, and the 2-3 shift delay valve. The reducing valve sleeve is lightly staked in the valve body bore. To remove the sleeve, use a blunt instrument against the end of the 2-3 shift valve and push the sleeve from its bore. Remove the 2-

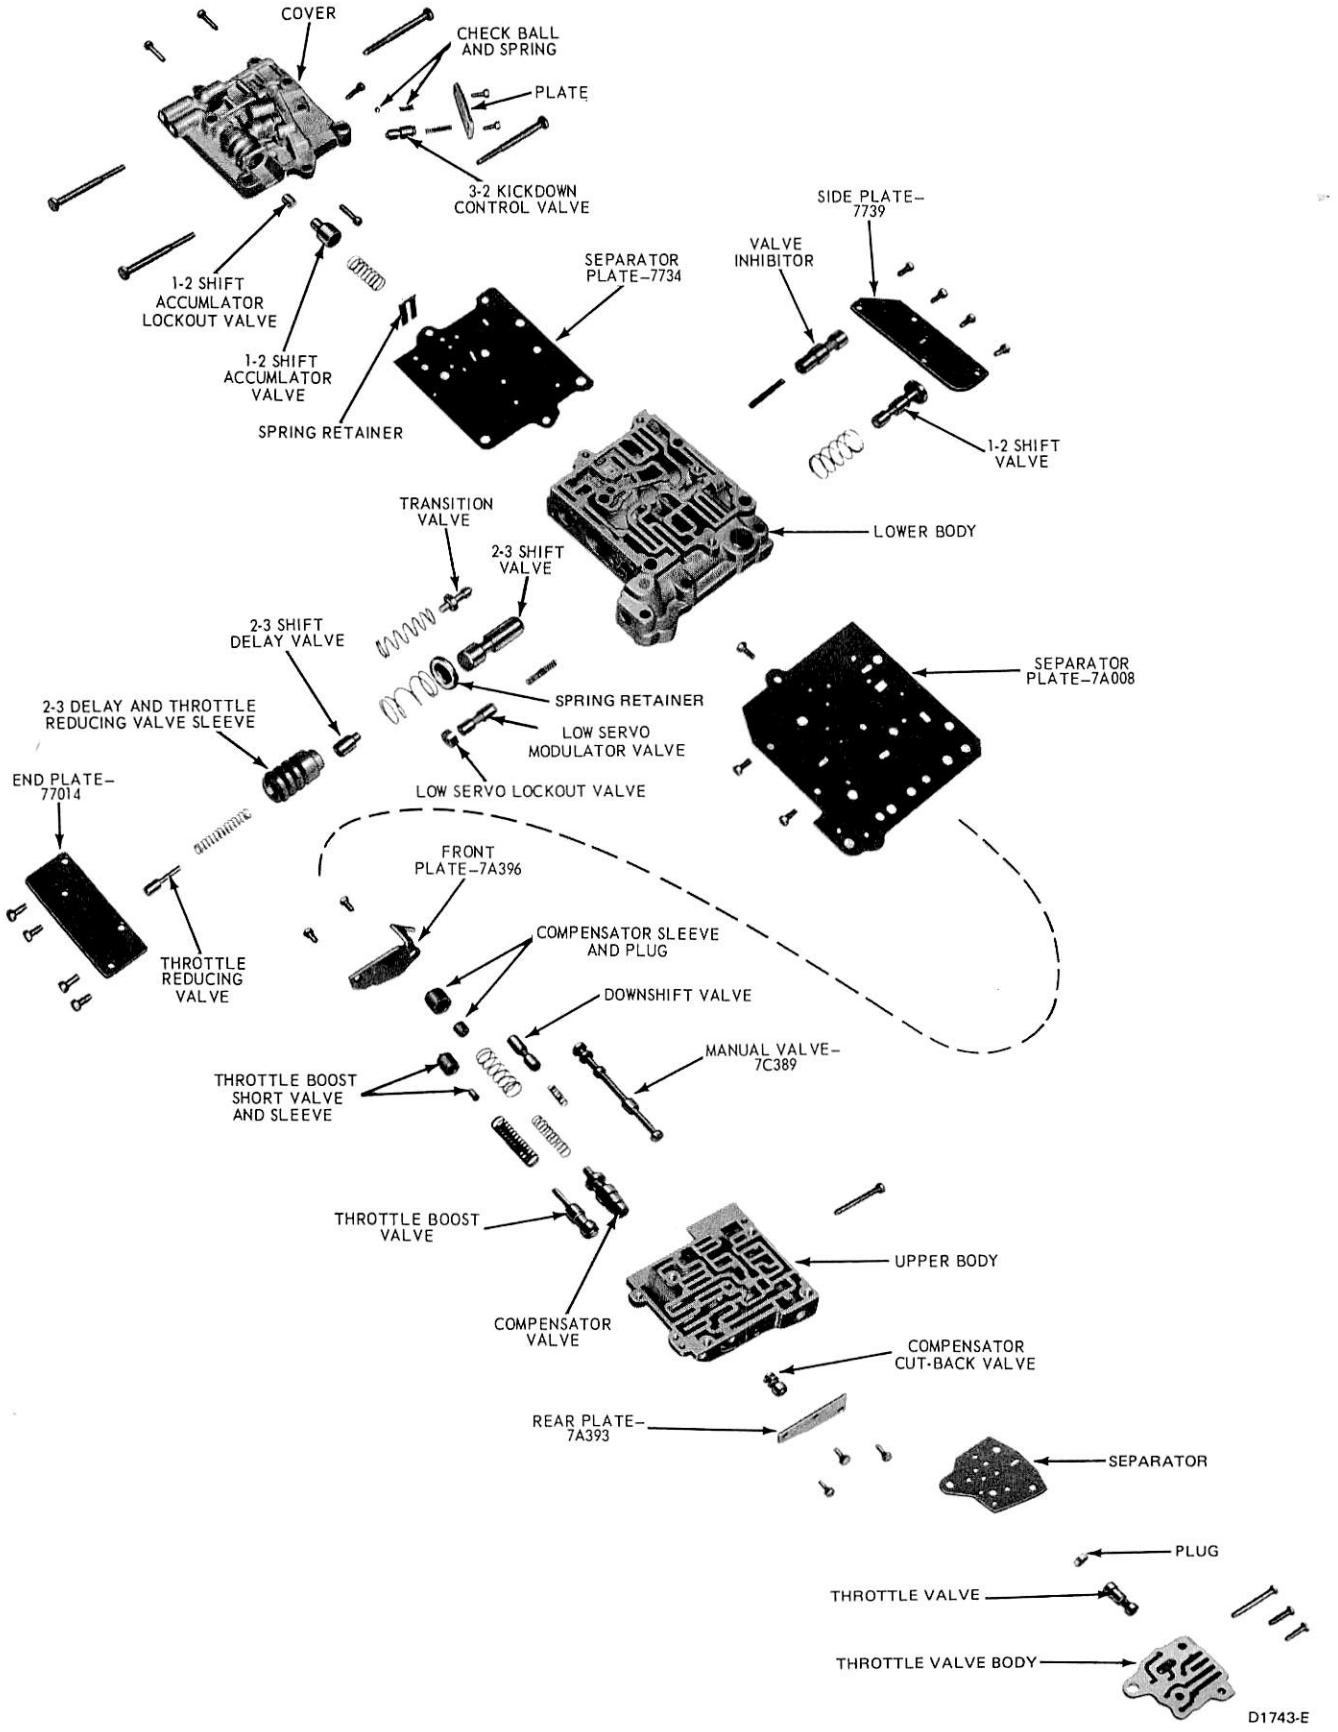

FIG. 21 Control Valve Body Disassembled

3 shift valve spring, spring retainer and valve.
14. Remove the transition valve spring and valve.
15. Remove the plate (Fig. 21) from the valve body cover.
16. Remove the check ball spring and check ball. Remove the 3-2 kickdown control valve spring and valve.
17. Remove the 1-2 shift accumulator valve spring retainer from the cover. Remove the spring, 1-2 shift accumulator valve and 1-2 shift accumulator lockout valve.
18. Remove the through bolts and screws. Then, separate the bodies. Remove the separator plates from the valve bodies and cover. Be careful not to lose the check valves.

Assembly

1. Arrange all parts in their correct positions (Fig. 21). Rotate the valves and plugs when inserting them in their bores to avoid shearing of soft body castings.
2. Place the check valve in the upper body as shown in Fig. 22. Then, position the separator plate on the body.
3. Position thelower body on the upper body, and start **but do not tighten the attaching screws.**
4. Position the cover and separator plate on the lower body. Start the four through bolts.
5. Align the separator with the upper and lower valve body attaching bolt holes. Install and torque the four valve body bolts to specification. **Excessive tightening of these bolts may distort the valve bodies, causing valves or plugs to stick.**
6. Install the 3-2 kickdown control valve and spring and the check ball and spring in the cover. Install the plate.
7. Insert the 1-2 shift accumulator lockout valve, 1-2 shift accumulator valve, and spring in the cover. Install the valve spring retainer.
8. Install the transition valve and spring in the lower body.
9. Install the 2-3 shift valve, spring retainer and spring. Install the 2-3 shift delay valve and the spring and throttle reducing valve in the sleeve. Slide the sleeve and valve into position in the lower body. Do not restake the sleeve.
10. Install the low servo lockout valve spring. Install the low servo modulator and low servo lockout valves. Install the lower body end plate.
11. Install the inhibitor valve spring and valve in the lower body.
12. Install the 1-2 shift valve spring and valve. Install the lower body side plate.
13. Install the compensator cutback valve in the upper body. Install the upper body rear plate.
14. Install the downshift valve and spring in the body.
15. Install the throttle boost valve and spring. Install the throttle boost short valve and sleeve.
16. Install the compensator valve, inner and outer compensator springs, and the compensator sleeve and plug.
17. Position the front plate. Apply pressure to the plate while installing the two attaching screws.
18. Install the throttle valve, plug and check valve in the throttle valve body. Position the separator on the upper body and install the throttle valve body. Install the three attaching screws.
19. Install four screws attaching the cover to the lower body, two screws attaching the separator plate to the upper body, and one screw attaching the separator plate to lower body. Torque the cover and body screws to specification.
20. Install the manual valve.

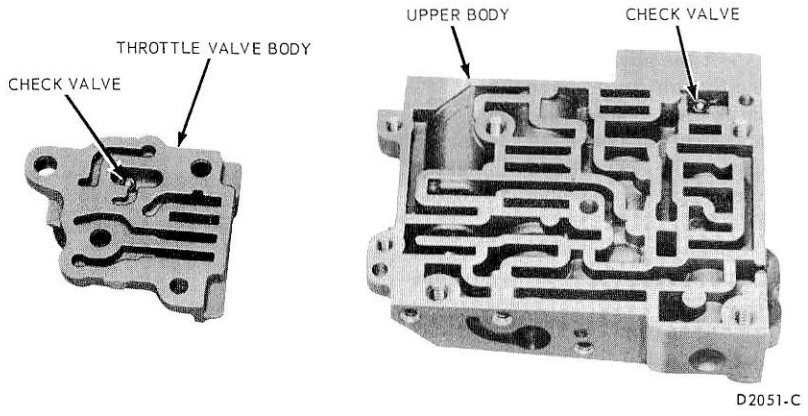

FIG. 22 Check Valve Locations

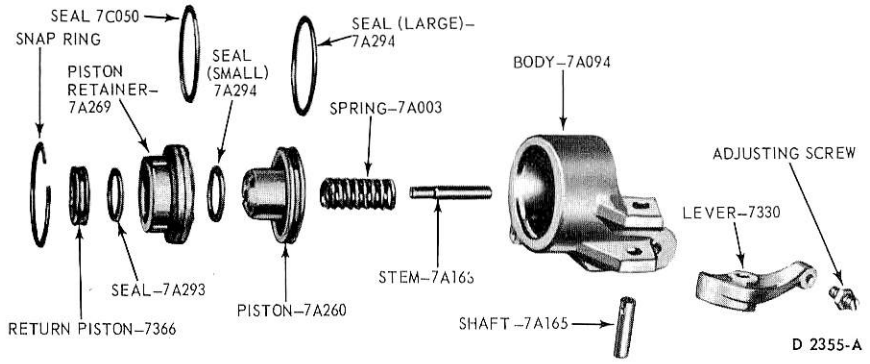

FIG. 23 Front Servo Disassembled

FRONT SERVO

Disassembly

1. Remove the servo piston retainer snap ring (Fig. 23). The servo piston is spring-loaded.**Apply pressure to the piston when removing the snap ring.**
2. Remove the servo piston retainer, servo piston, and the return piston from the servo body. It may be necessary to tap the piston stem lightly with a soft-faced hammer to separate the piston retainer from the servo body.
3. Remove all the seal rings, and remove the spring from the servo body.
4. Inspect the servo body for cracks and the piston bore and the servo piston stem for scores (Fig. 23). Check fluid passages for obstructions.
5. Check the actuating lever for free movement, and inspect it for wear. To replace the actuating lever shaft, it will be necessary to press the shaft out of the bracket. The shaft is retained in the body by serrations on one end of the shaft. These

serrations cause a press fit at that end. To remove the shaft, press on the end opposite the serrations.

Inspect the adjusting screw threads and the threads in the lever.

6. Check the servo spring and servo band strut for distortion.
7. Inspect the servo band lining for excessive wear and bonding to the metal.

The band should be replaced if worn to a point where the grooves are not clearly evident.

8. Inspect the band ends for cracks and check the band for distortion.

Assembly

1. Lubricate all parts of the front servo with transmission fluid to facilitate assembly.
2. Install the inner and outer O-rings on the piston retainer. Install a new O-ring on the return piston and on the servo piston (Fig. 23).
3. Position the servo piston release spring in the servo body. Install the servo piston, retainer, and return piston in the servo body as an assembly. Compress the assembly into the body, and secure it with the snap ring.**Make sure the snap ring is fully seated in the groove.**
4. Install the adjusting screw and lock nut in the actuating lever if they were previously removed.

REAR SERVO

Disassembly

1. Remove the servo actuating lever shaft retaining pin with a 1/8 inch punch. Remove the shaft, actuating lever needle bearings and thrust washers if so equipped.
2. Press down on the servo spring retainer, and remove the snap ring. **Release the pressure on the retainer slowly to prevent the spring from flying out.**
3. Remove the retainer and servo spring (Fig. 24).
4. Force the piston out of the servo body with air pressure. Hold one hand over the piston to prevent damage.
5. Remove the accumulator piston from the servo piston.
6. Remove the piston seal ring.

Assembly

1. Install a new seal ring on the servo piston.
2. Install the accumulator piston in the servo piston.
3. Install the piston in the servo body. **Lubricate the parts to facilitate assembly.**Install the servo spring with the small coiled end against the servo piston.

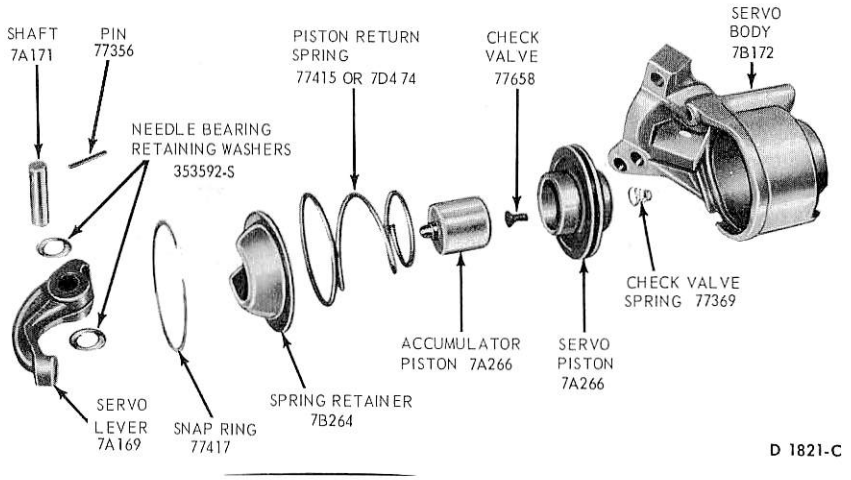

FIG. 24 Rear Servo Disassembled

4. Install the spring retainer. Compress the spring with a C-clamp. Then install the snap ring.**The snap ring must be fully seated in the groove.**
5. Install the needle bearings (if so equipped) in the actuating lever. Install the actuating lever and thrust washers (if so equipped) with the socket in the lever bearing on the piston stem. Install the actuating lever shaft, aligning the retaining pin holes, and install the pin.
6. Check the actuating lever for free movement.

GOVERNOR

Disassembly

1. Remove the governor valve body cover.
2. Remove the valve body from the counterweight.
3. Remove the plug, sleeve, and the valve and spring from the body (Fig. 25).
4. Remove the screen from its bore in the valve body.

Assembly

1. Install the governor valve and spring assembly in the bore of the valve body. Install the sleeve, and plug.
2. Install the screen.
3. Install the body on the counterweight.**Make sure the fluid passages in the body and the counterweight are aligned.**
4. Position the valve body cover on the body, and install the screws.

PRESSURE REGULATOR

Disassembly

1. Remove the valves from the regulator body.

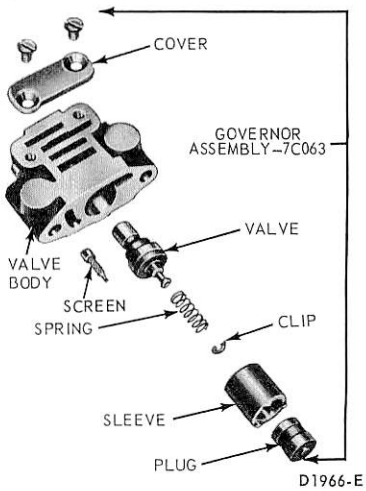

FIG. 25 Governor Disassembled

2. Remove the regulator body cover attaching screws, and remove the cover (Fig. 26).
3. Remove the separator plate.
4. Wash all parts thoroughly in clean solvent and blow dry with moisture-free compressed air.
5. Inspect the regulator body and cover mating surfaces for burrs.
6. Check all fluid passages for obstructions.
7. Inspect the control pressure and converter pressure valves and bores for burrs and scores. Remove all burrs carefully with crocus cloth.
8. Check the free movement of the valve in their bores. Each valve should fall freely into its bore when both the valve and bore are dry.
9. Inspect the valve springs for distortion.

Assembly

1. Position the separator plate on the regulator cover.
2. Position the regulator cover and separator plate on the regulator body, and install the attaching screws. Torque the screws to specification.
3. Insert the valves in the pressure regulator body (Fig. 26).

DOWNSHIFT AND MANUAL LINKAGE

Disassembly

1. Remove the inner downshift lever shaft nut (Fig. 27). Then remove the inner downshift lever.
2. Remove the outer downshift lever and shaft. Remove the downshift shaft seal from the counterbore in the manual lever shaft.
3. Remove the cotter pin from the parking pawl toggle operating rod and remove the clip from the parking pawl operating lever. Remove the parking pawl operating rod.
4. Rotate the manual shaft until the detent lever clears the detent plunger. Then remove the detent plunger and spring. **Do not allow the detent plunger to fly out of the case.**
5. Remove the manual lever shaft nut, and remove the detent lever. Remove the outer manual lever and shaft from the transmission case.
6. Tap the toggle lever sharply toward the rear of the case to remove the plug and pin.
7. Remove the pawl pin by working the pawl back and forth. Remove the pawl and toggle lever assembly, and then disassemble.
8. Remove the manual shaft seal and case vent tube.

Assembly

1. Coat the outer diameter of a new manual shaft seal with sealer, then install the seal in the case with a driver.
2. Install the vent tube in the transmission case.
3. Assemble the link to the pawl with the pawl link pin, washer, and pawl return spring. Assemble the toggle lever to the link with the toggle link pin. Position the pawl return spring over the toggle link pin, and secure it in place with the washer and the small retainer clip (Fig. 27). Install the assembly in the transmission case by installing the pawl pin and the toggle lever pin. Install the torsion lever assembly. Position the spring on the torsion lever with a screwdriver. Make certain that the short side of toggle does not extend beyond the largest diameter of the ball or the toggle lever pin (Fig. 27). Tap the toggle lever in or out as necessary to center the toggle lever on the ball.
4. Install the manual lever and shaft in the transmission case. Position the detent lever on the shaft, and secure it with a nut. Tighten the nut to 20-30 ft-lbs torque. Rotate the manual lever to the rear of the case. Position the detent spring in the case. Hold the detent plug on the spring with a 3/16 inch socket wrench, then depress the spring until the plug is

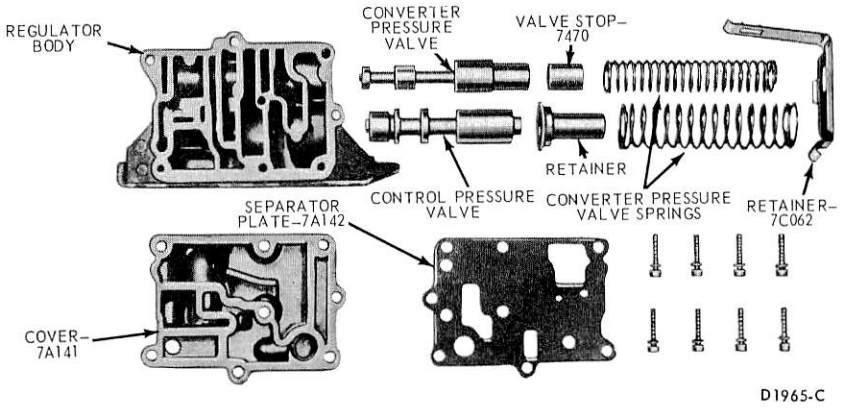

FIG. 26 Pressure Regulator Disassembled

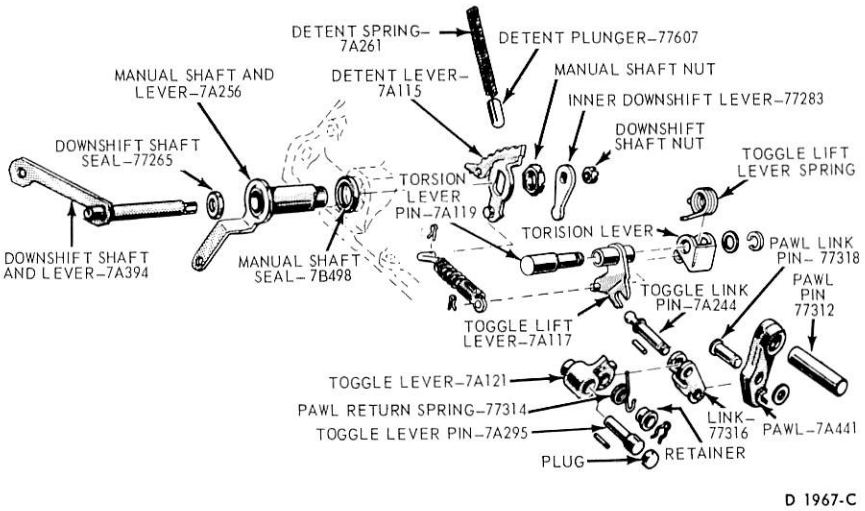

FIG. 27 Transmission Case Control Linkage

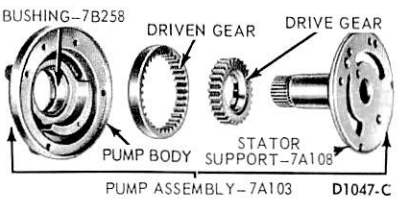

FIG. 28 Front Pump Disassembled

flush with the case. Carefully rotate the manual lever to the front of the case to secure the plug.**A piece of thin walled tubing may be used to depress the plug if a small socket wrench is not available.**

5. Position the ends of the parking pawl operating rod in the detent lever and toggle lift lever, and secure with the two small retaining pins.
6. Install a new seal on the downshift lever shaft, then install the lever and shaft in the case. Position the inner downshift lever on the inner end of the shaft with the mark 0 facing toward the center of the case. Install the lock washer and nut, then tighten the nut to 17-20 ft-lbs torque.
7. Check the operation of the linkage. The linkage should operate freely without binding.

FRONT PUMP

Disassembly

1. Remove the stator support attaching screws and remove the stator support. Mark the top surface of the pump driven gear with Prussian blue to assure correct assembly.**Do not scratch the pump gears.**
2. Remove the drive and driven gears from the pump body.
3. Refer to Fig. 28 for a disassembled view of the front pump. Inspect the pump body housing, gear pockets and crescent for scores.
4. If the pump housing bushing is to be replaced, press the bushing from the front housing with the tools shown in Fig. 29.
5. Press a new bushing into the pump housing with the handle and tool shown in Fig. 29.
6. If any parts other than the stator support, bushings or oil seal are found defective, replace the pump as a unit. Minor burrs and scores may be removed with crocus cloth. The stator support is serviced separately.
7. Bolt the front pump to the transmission case with capscrews.
8. If the oil seal requires replacement, install the oil seal remover shown in Fig. 30. Then pull the front seal from the pump body.
9. Clean the pump body counterbore. Then inspect the bore for rough spots. Smooth up the counterbore with crocus cloth.
10. Remove the pump body from the transmission case.

Assembly

1. If the oil seal was removed, coat the outer diameter of a new seal with FoMoCo sealing compound, or its equivalent. Then position the seal in the pump body. Drive the seal into the pump body with the tool shown in Fig. 31 until the seal is firmly seated in the body.
2. Place the pump driven gear in the pump body with the mark on the gear facing down. Install the drive gear in the pump body with the chamfered side of the flats facing down.
3. Install the stator support and attaching screws. Check the pump gears for free rotation.

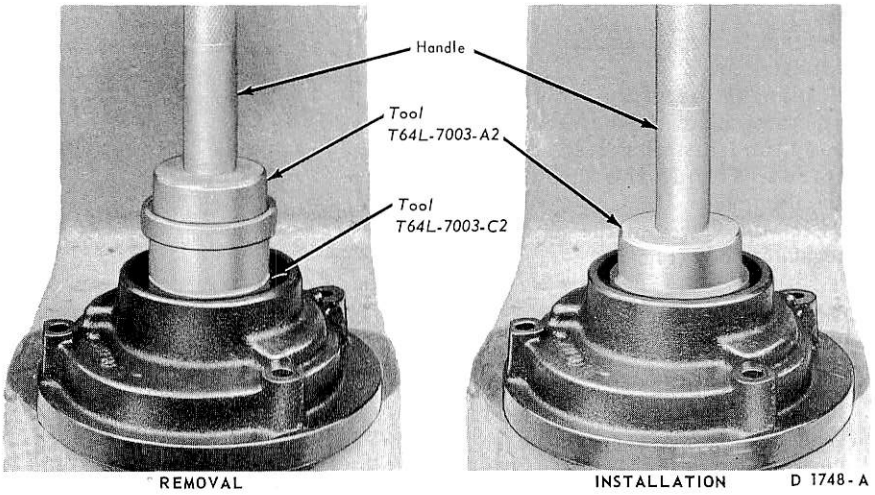

FIG. 29 Replacing Front Pump Housing Bushing

REAR PUMP

Disassembly

1. Remove the screws and lock washers which secure the pump cover to the pump body, and remove the cover.
2. Remove the drive gear from the pump body.
3. If the pump housing bushing is worn or damaged, replace the bushing with the tools shown in Fig. 32.

Assembly

1. Install the drive gear in the pump body.
2. Install the pump cover, attaching screws, and lock washers. Torque the screws to specification.

REAR CLUTCH

Disassembly

1. Remove the clutch pressure plate snap ring, and remove the pressure plate from the drum. Remove the waved cushion spring. Remove the composition and steel plates.
2. Compress the spring with the tools shown in Fig. 33 and remove the snap ring.
3. Guide the spring retainer while releasing the pressure to prevent the retainer from locking in the snap ring grooves.
4. Position the primary sun gear shaft in the rear clutch. Place an air hose nozzle in one of the holes in the shaft, and place one finger over the other hole. Then force the clutch piston out of the clutch drum with air pressure.**Hold one hand over the piston to prevent damage to the piston.**
5. Remove the inner and outer seal rings from the clutch piston.

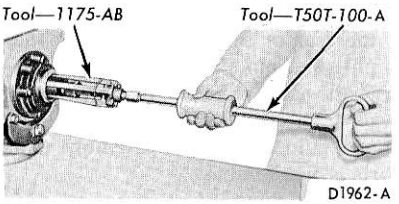

FIG. 30 Removing Front Pump Seal

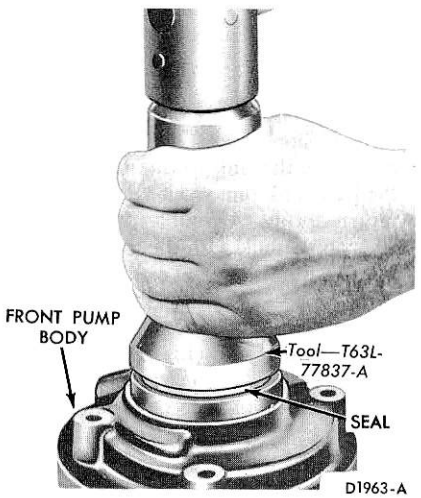

FIG. 31 Installing From Pump Seal

6. Remove the rear clutch sun gear bushing if it worn or damaged. Use the cape chisel (Fig. 34) and cut along the bushing seam until the chisel breaks through the bushing wall. Pry the loose ends of the bushing up with an awl and remove the bushing.

Assembly

1. If the rear clutch sun gear bushing was removed, press a new bushing into the rear clutch sun gear with the tool shown in Fig. 35.
2. Install new inner and outer seal rings on the piston.
3. To install the piston in the clutch drum, lubricate the piston seals and tools (Fig. 36) with clean transmission fluid. Push the small fixture down over the cylinder hub. Insert the piston into the large fixture with the seal toward the thin-walled end. Hold the piston and large fixture and insert as a unit into the cylinder. Push down over the small fixture until large tool stops against the shoulder in the cylinder; then push the piston down, out of the tool, until it bottoms in the cylinder, remove the tools.
4. Install the clutch release spring, and position the retainer on the spring.
5. Install the tool on the spring retainer as shown in Fig. 33. Compress the clutch spring, and install the snap ring. **While compressing the spring, guide the retainer to avoid interference of the retainer with the snap ring groove. Make sure the snap ring is fully seated in the groove.** When new composition clutch plates are used, soak the plates in automatic transmission fluid for 15 minutes before they are assembled.
6. Install the external tabbed waved cushion spring. Then, install the composition and the steel clutch plates alternately, starting with a steel plate.
7. Install the clutch pressure plate with the bearing surface down. Then install the clutch pressure plate snap ring. Make sure the snap ring is fully seated in the groove.
8. Check the free pack clearance between the pressure plate and the first internal plate with a feeler gauge. The clearance should be 0.030-0.055 inch. If the clearance is not within specifications, selective snap rings are available in the following thicknesses; 0.060-0.064, 0.074-0.078, 0.088-0.092 and 0.102-0.106 inch. Insert the correct size snap ring and recheck the clearance.

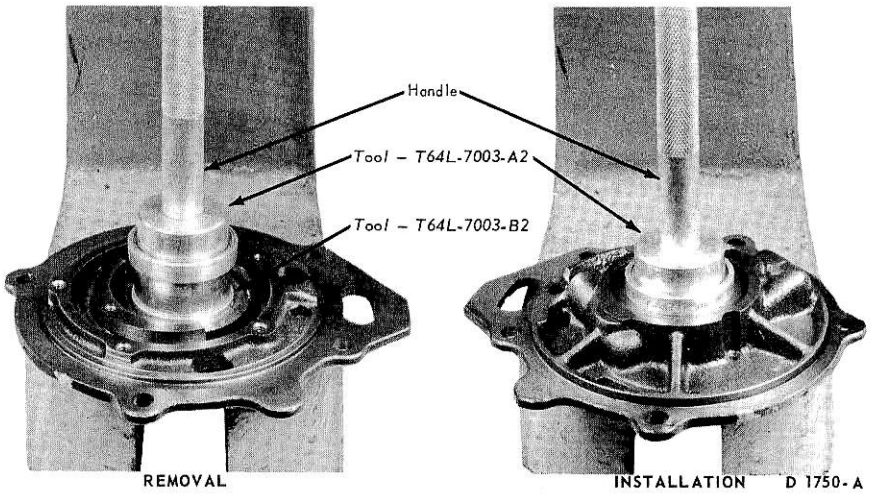

FIG. 32 Replacing Rear Pump Housing Bushing

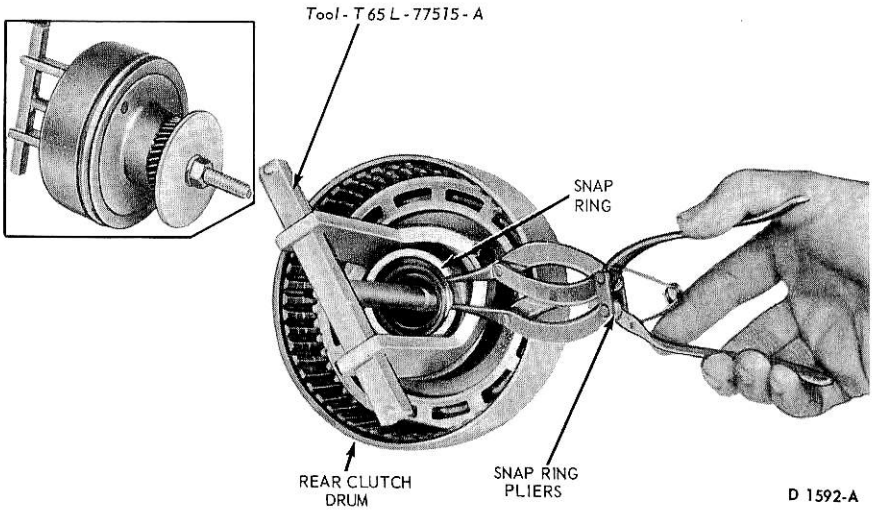

FIG. 33 Removing Rear Clutch Spring Snap Ring

9. Install the thrust washer on the primary sun gear shaft. Be sure the thrust washer is installed with the tabs of the washer away from the sun gear thrust face. Lubricate all parts with automatic transmission fluid or petroleum jelly. Install the two center seal rings.
10. Install the rear clutch on the primary sun gear shaft. **Be sure all of the needles are in the hub if the unit is equipped with loose needle bearings.** Assemble two seal rings in the front grooves.
11. Install the steel and the bronze thrust washers on the front of the secondary sun gear assembly. If the steel washer is chamfered, place the chamfered side down.

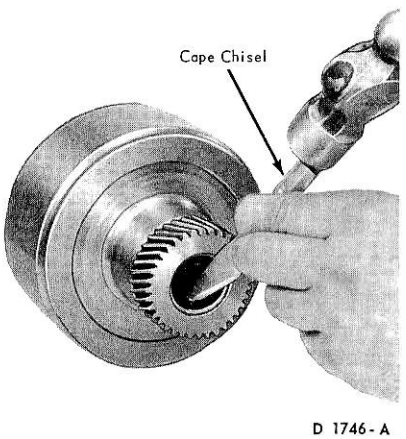

FIG. 34 Removing Rear Clutch Sun Gear Bushing

FRONT CLUTCH

Disassembly

1. Remove the clutch cover snap rings

with a screwdriver, and remove the input shaft from the clutch drum.
2. Remove the thrust washer from the thrust surface of the clutch hub. Insert one finger in the clutch hub, and lift the hub straight up to remove the hub from the clutch drum.
3. Remove the composition and the steel clutch plates, and then remove the pressure plate from the clutch drum.
4. Place the front clutch spring compressor on the release spring, position the clutch drum on the bed of an arbor press, and compress the release spring with the arbor press until the release spring snap ring can be removed (Fig. 37).
5. Remove the clutch release spring from the clutch drum.
6. Install the special nozzle shown in Fig. 38 on an air hose. Place the nozzle against the clutch apply hole in the fron clutch housing, and force the piston out of the housing.
7. Remove the piston inner seal from the clutch housing. Remove the piston outer seal from the groove in the piston.
8. Remove the input shaft bushing if it is worn or damaged. Use the cape chisel and cut along the bushing seam until the chisel breaks through the bushing wall. Pry the loose ends of the bushing up with an awl and remove the bushing.

Assembly

1. If the input shaft bushing was removed, slip a new bushing over the end of the installation tool and position the tool and bushing to the bushing hole. Then, press the bushing into the input shaft as shown in Fig. 39.
2. Lubricate all parts with transmission fluid. Install a new piston inner seal ring in the clutch cylinder. Install a new piston outer seal in the groove in the piston.
3. Install the piston in the clutch housing. Make sure the steel bearing ring is in place on the piston.
4. Position the release spring in the clutch cylinder with the concave side up. Place the release spring compressor on the spring, and compress the spring with an Arbor Press. Then install the snap ring as shown in Fig. 37. **Make sure the snap ring is fully seated in the groove.**
5. Install the front clutch housing on the primary sun gear shaft by rotating the clutch units to mesh the rear clutch plates with the serrations on the clutch hub. **Do not breake the seal rings.**

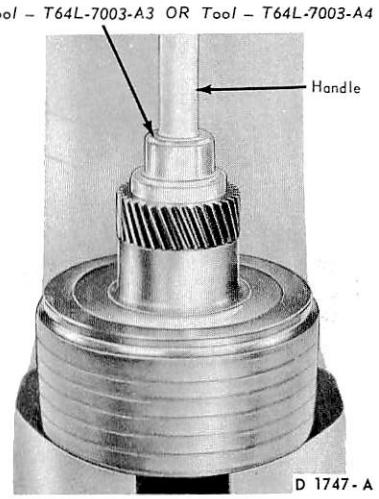

FIG. 35 Installing Rear Clutch Sun Gear Bushing

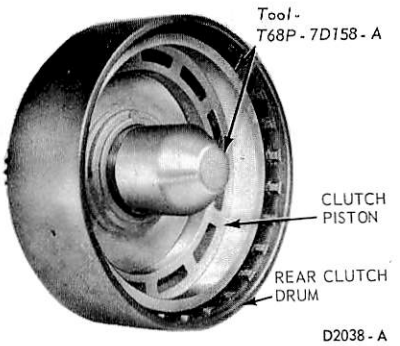

FIG. 36 Installing Rear Clutch Piston

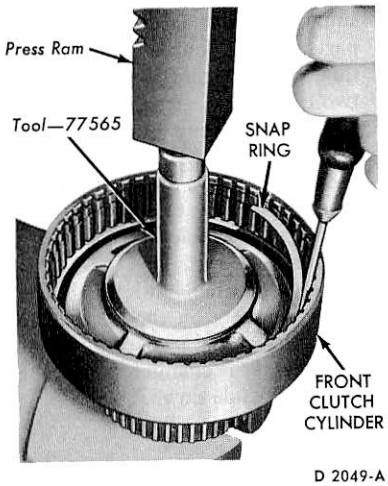

FIG. 37 Removing or Installing Front Clutch Snap Ring

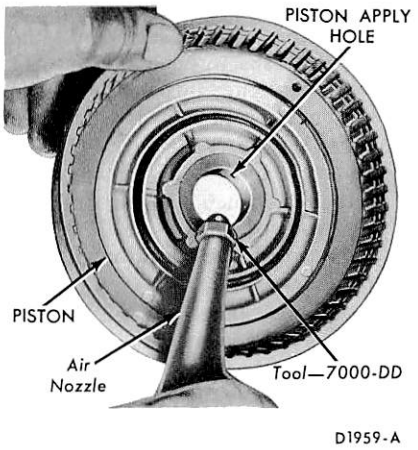

FIG. 38 Removing Front Clutch Piston

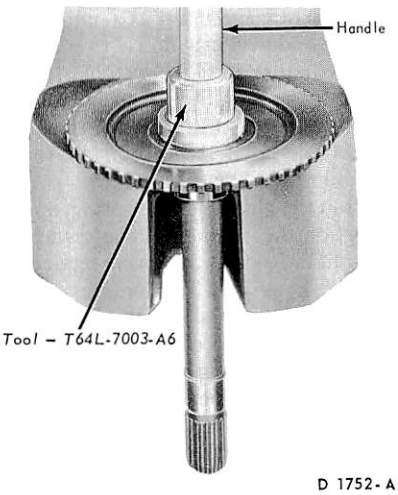

FIG. 39 Installing Input Shaft Bushing

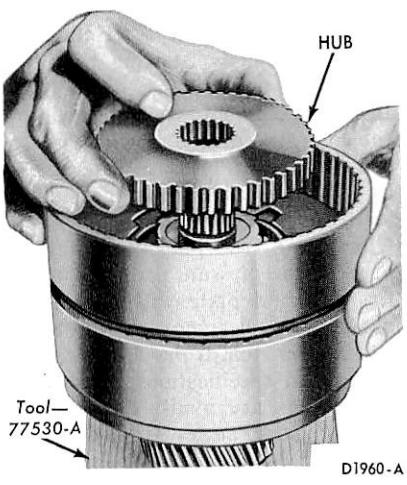

FIG. 40 Installing Front Clutch Hub

6. Install the clutch hub in the clutch cylinder with the deep counterbore down (Fig. 40). Install the thrust washer on the clutch hub.
7. Install the pressure plate in the clutch cylinder with the bearing surface up (Fig. 41). Install the composition and the steel clutch plates alternately, starting with a composition plate (Fig. 42). When new composition clutch plates are used, soak the plates in automatic transmission fluid for 15 minutes before they are assembled.

The final friction plate to be installed is selective. Install the thickest plate that will be a minimum of 0.010 inch below input shaft shoulder in cylinder. For all other plates, use the thinnest available. Refer to the Specifications Section for available plate thicknesses.

8. Install the turbine shaft in the clutch cylinder, and then install the snap ring. **Make sure the snap ring is fully seated in the groove.**
9. Install the thrust washer on the turbine shaft.

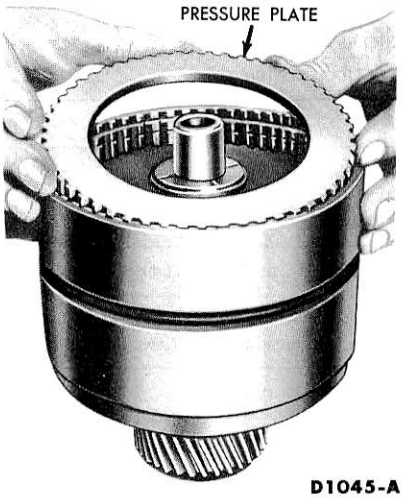

FIG. 41 Installing Pressure Plate

PRIMARY SUN GEAR SHAFT

Disassembly

1. Position the primary sun gear shaft in the clutch bench fixture.

FIG. 42 Installing Clutch Plates

2. Check the fit of the seal rings in their respective bores. A clearance of 0.002-0.009 inch should exist between the ends of the rings.

Assembly

1. Replace the seal rings, and check for free movement in the grooves.

DESCRIPTION

TRANSMISSION

The AT-540 transmission is hydraulically operated with four forward ranges and one reverse range. Figure 1 shows the location of the converter, gear train and most of the internal parts used in the transmission.

The transmission consists basically of a hydraulic torque converter, a planetary gear train and a hydraulic control system which automatically changes gear ratios and supplies oil under pressure to the converter and to the lubrication circuits (Fig. 2).

The torque converter multiples engine torque and acts as a fluid coupling between the engine and transmission gearing while starting and during the automatic gear shifts.

The transmission gearing consists of three sets of constant mesh planetary gears that are operated by hydraulically actuated disk-type clutches which provide smooth, full-power shifting.

The clutches are oil cooled and self-adjusting— automatic compensation for wear. The gear train includes First, Second, Third, and Fourth clutches with a forward clutch applied in all forward ranges.

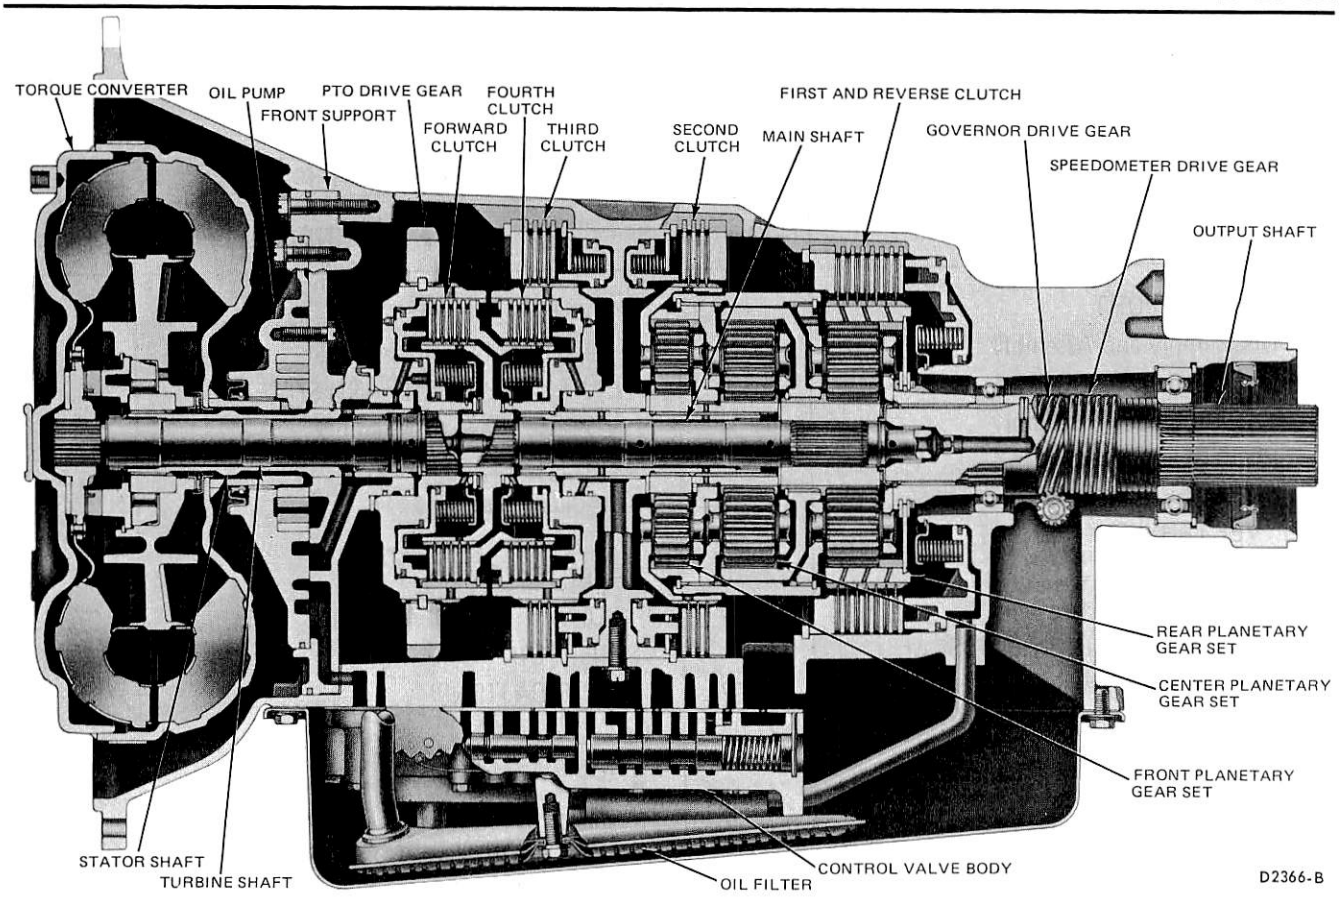

FIG. 1 Transmission Gear Train

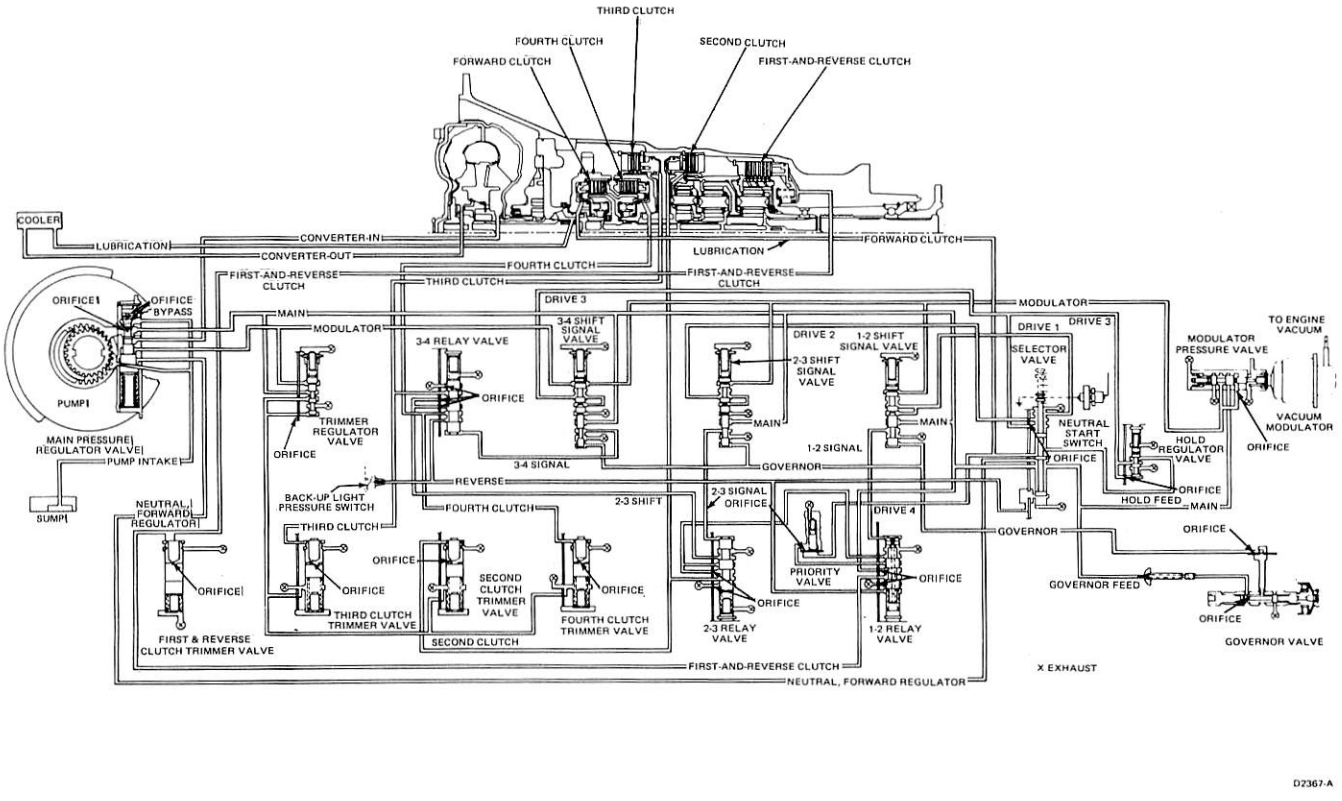

FIG. 2 Hydraulic Control System

TESTING

When diagnosing transmission problems, refer to the Truck Diagnosis Manual for the detailed information on the items that could be causing the problem.

TRANSMISSION FLUID LEVEL CHECK

1. With the vehicle standing level, apply the parking brake, and place the range selector lever in N. Operate the engine at idle speed.
2. If the transmission fluid is cold, operate the transmission until normal operating temperature (150 degrees to 200 degrees F) is reached.
3. When the engine and transmission have reached their normal operating temperatures, move the selector lever through all the range positions to make sure that warm fluid is distributed throughout the transmission. Return the selector lever to N.
4. Clean around the end of the fill pipe before removing the dipstick.
5. Check fluid level on dipstick. The safe operating level is between the ADD and FULL marks on the dipstick. If fluid level is low, add sufficient fluid to bring level to the FULL mark. If level is too high, drain excess fluid to proper level.

STALL TEST

A stall test should be conducted when the power package (engine and transmission) is not performing satisfactorily. The purpose of the test is to determine if the transmission is the malfunctioning component.

Start the engine to allow it to reach its normal temperature. Apply both the parking and service brakes and, if necessary, block the vehicle to prevent any forward or reverse movement.

The stall test is made in gear at full throttle to check engine performance, converter and the holding ability of the clutches. **While making this test, do not maintain the stalled condition longer than 30 seconds due to rapid heating of the transmission oil. With the transmission in neutral, run the engine at 1200 to 1500 rpm for two minutes to cool the oil between tests. Do not allow the converter-out temperature to exceed 300 degrees F. Keep close check to prevent the engine cooling system from overheating.**

With the transmission in gear and the engine at full throttle, note the maximum speed the engine will attain. Then compare the speed with the limits shown in the Specification Section. An engine speed above or below the specified range may indicate a malfunction in the engine or transmission.

SHIFT POINT CHECKS

The Specification Booklet outlines the engine speeds at which the various shifts should occur.

SELECTOR LEVER LINKAGE CHECK

Proper adjustment of the manual selector lever linkage is important because the shift tower gate positions must correspond exactly to the detents in the transmission. Periodic checks should be made for bent or worn parts, loose bolts and threaded connections and an accumulation of grease and dirt. All moving joints must be kept clean and well lubricated.

The selector lever should move easily and give a feel of positive engagement in each position. The pin which engages the shift lever linkage at the transmission should move freely in each range.

VACUUM MODULATOR CHECK

To check for a vacuum diaphragm leak, insert a pipe cleaner into the vacuum connector pipe as far as possible and check for the presence of transmission fluid. If fluid is found replace the modulator. Gasoline or water vapor may settle in the vacuum side of the modulator. If this is found without the presence of fluid, the modulator need not be changed.

To check the modulator for an atmospheric leak, apply a liberal coating of soap bubble solution to the vacuum connector pipe seam, crimped upper-to-lower housing seam and threaded screw seal. Using a short piece of rubber tubing, apply air pressure to the vacuum pipe by blowing into the tube and observe for leak bubbles. If bubbles appear, replace the modulator. **Do not use more than 6 psi air pressure, as pressure over 6 psi may damage the modulator.**

TORQUE CONVERTER TESTS

Because the torque converter assembly is closed and welded after assembly of the internal parts, no repairs can be made. The assembly can be tested, however, to determine its condition in two areas. End play of the internal elements can be measured, and the outer shell can be tested for leaks.

CONVERTER END PLAY CHECK

1. Clear the torque converter of oil. Examine the oil for evidence of foreign matter or metal, indicating internal damage.
2. Insert the converter end play checking tool (Fig. 3) into the converter hub until it bottoms.
3. Attach a dial indicator to the tool (Fig. 3). Expand the split bushing in the turbine spline by tightening the adjusting nut. Tighten the adjusting nut until the tool is securely locked into the spline.
4. Position the indicator button on the converter hub and set the dial face at 0 (zero).
5. Lift the tool upward as far as it will go and note the indicator reading. If the end play exceeds 0.050 inch, the torque converter assembly should be replaced.

CONVERTER LEAKAGE CHECK

1. Clear the torque converter of oil. Examine the oil for foreign matter or metal, indicating internal damage.
2. Place the torque converter leak test tool on the converter hub (Fig. 4) and hand tighten the knurled portion of the tool to hold it securely in place.
3. Pressurize the converter to a maximum of 75 psi. Submerge the pressurized assembly in water and observe closely for bubbles that indicate leakage. If the assembly leaks, it should be replaced.
4. Release the air from the torque converter by pushing on the valve

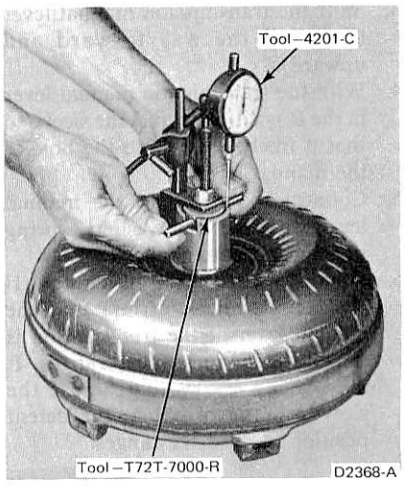

FIG. 3 Checking Converter End Play

stem in the air fitting on the tool. **Be sure that all pressure is completely exhausted from the converter before removing the tool.**

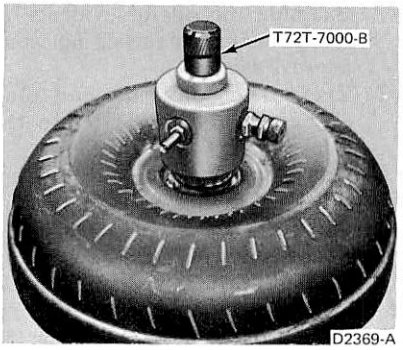

FIG. 4 Converter Leak Checking Tool

ADJUSTMENTS

NEUTRAL START SWITCH

Check the starter circuit at all selector lever positions. The circuit must be open at all positions except N (neutral). To adjust, loosen the neutral switch to bracket attaching screws (Fig. 5). Position the switch so that the starter circuit is closed when the selector lever is at N.

SELECTOR LEVER LINKAGE

1. With the engine stopped, position the transmission selector lever in the R position.
2. Disconnect the shift cable sleeve at the transmission manual lever (Fig. 6).
3. Shift the transmission manual lever to R (all the way forward and upward).
4. With the transmission manual lever in the R position, adjust the sleeve so that it freely enters into the hole of the manual lever.
5. Connect the sleeve to the manual lever with the flat washers, spring washer and cotter pin.
6. Operate the shift lever in all positions to make certain that the manual lever at the transmission is in full detent in all gear ranges. It may be necessary to readjust the sleeve slightly to obtain the detent position in all drive ranges.

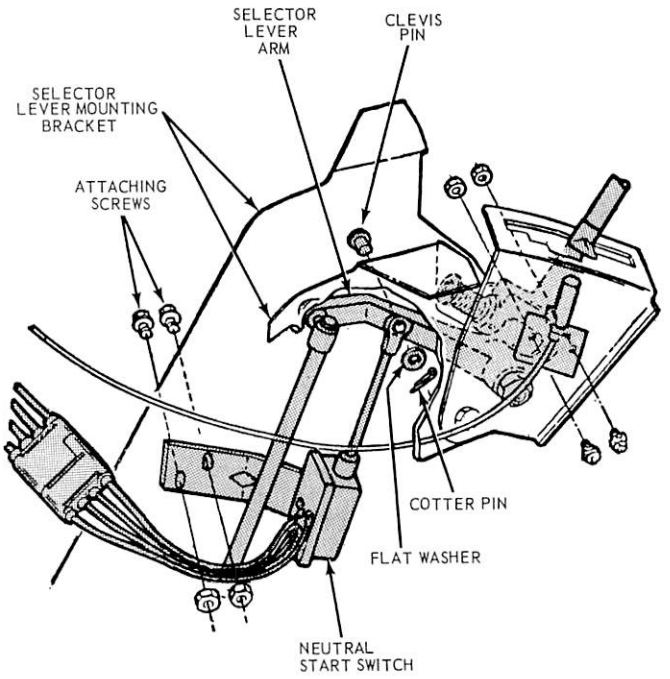

FIG. 5 Neutral Start Switch

THROTTLE LINKAGE ADJUSTMENTS

The throttle linkage should be adjusted whenever the engine idle speed is changed, and whenever the transmission operation indicates that adjustment is required. Refer to Group 24 for the detailed throttle linkage adjustment procedures.

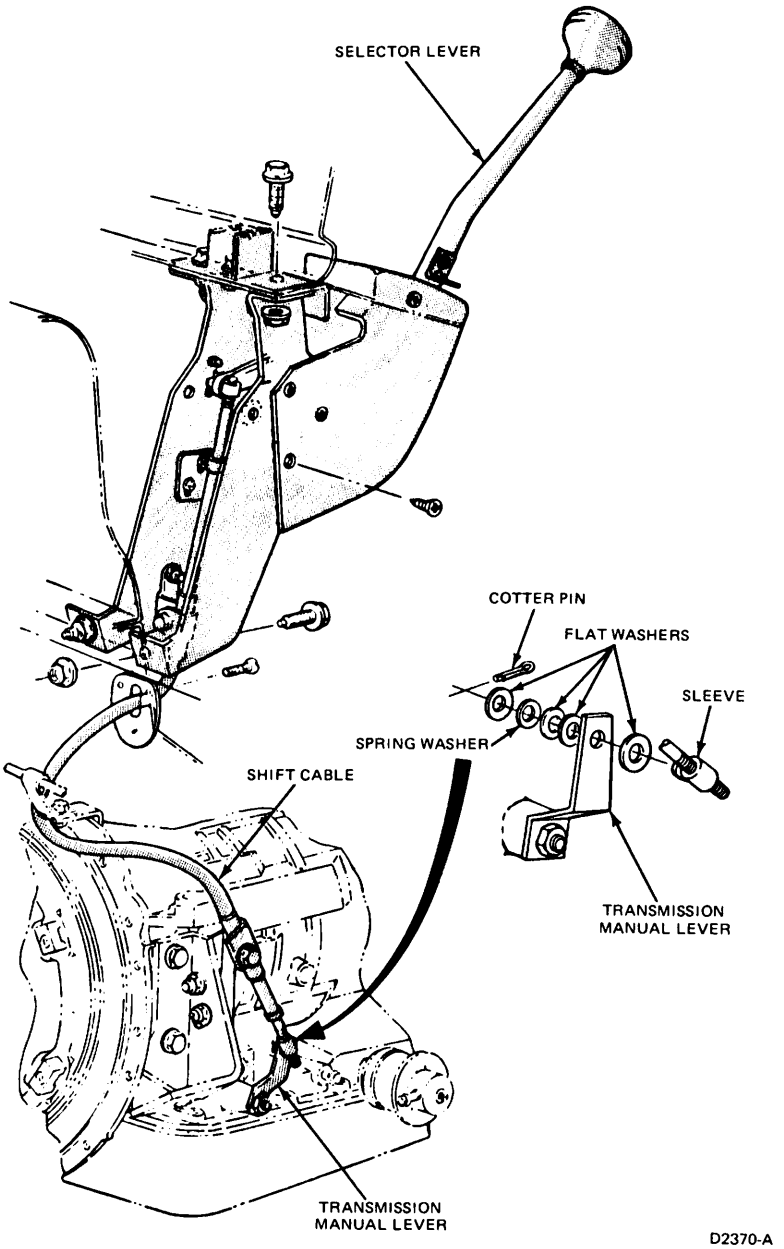

FIG. 6 Selector Lever Linkage—Typical

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. From inside the vehicle, remove the right and left door sill scuff plate screws and remove the plates. Position the floor covering out of the way. Remove the bolts securing the transmission access cover to the floor pan and remove the cover.
2. On a one-piece drive shaft, disconnect the shaft from the yoke at the parking brake drum. On a two-piece drive shaft, disconnect the coupling shaft from the yoke at the parking brake drum, and then remove the center support bearing bracket. Move the forward end of the drive shaft out of the way.
3. Disconnect the parking brake linkage and remove the parking brake drum from the output shaft flange.
4. Remove the parking brake handle and brackets from the transmission case.
5. Place a drain pan under the transmission. Disconnect the filler tube from the transmission pan and allow the fluid to drain.
6. Disconnect the speedometer cable from the rear of the transmission.
7. Disconnect the oil cooler lines at the transmission.
8. Disconnect the vacuum line from the vacuum modulator.

9. Remove the vacuum modulator retainer bolt and remove the retainer. Remove the vacuum modulator and valve actuating rod from the case.
10. Disconnect the shift cable from the manual lever at the transmission.
11. Remove the two bolts that secure the shift cable bracket to the transmission and position the cable and bracket out of the way.
12. Remove the inspection cover from the bottom front side of the flywheel housing.
13. Remove the six converter-to-flywheel attaching bolts.
14. Remove four upper and two lower converter housing-to-flywheel attaching bolts.
15. Remove the bolts and nuts securing the two rear engine supports to the crossmember. Remove the lower insulators and flat washers.
16. Loosen the front engine support bolts.
17. Position a transmission jack under the transmission and secure the transmission to the jack with safety chain.
18. Place a jack under the engine, then raise both jacks to take the weight off the crossmember.
19. Remove the two upper engine rear support insulators from the crossmember.
20. Remove the bolts securing the engine rear support brackets to the transmission and remove the brackets.
21. With both jacks supporting the engine and transmission, remove the remaining converter housing-to-flywheel attaching bolts.
22. Pull the transmission rearward until the converter housing contacts the body sheet metal (Fig. 7). Then tilt the rear of the transmission up until the bottom of the converter housing clears the crossmember (Fig. 7). Lower the unit and remove it from under the vehicle. If necessary, raise the rear of the truck to permit the transmission to clear the frame.

Installation

1. Position the torque converter to the transmission, engaging the turbine shaft with the converter turbine, the stator shaft with the stator, and the hub with the oil pump drive gear.
2. With the converter properly installed, place the transmission on the jack. Secure the transmission to the jack with safety chain.
3. Raise the converter and transmission on the jack, then move the assembly into position over the crossmember (Fig. 7). Align the holes in the converter with the holes in the flywheel.
4. Install six converter housing-to-flywheel attaching bolts (three on each side). Torque the bolts to specification.
5. Lower the engine jack and remove it from under the vehicle.
6. Position the engine rear support brackets to the sides of the transmission and secure with the attaching bolts.
7. Position the two upper engine rear support insulators on the crossmember. Position the lower insulators and flat washers to the crossmember and install the rear support-to-crossmember bolts and nuts. Torque the bolts to specification.
8. Lower the transmission jack and remove it from under the vehicle.
9. Install the four upper and two lower converter housing-to-flywheel attaching bolts.
10. Torque the front engine support bolts to specification.
11. Install the six converter-to-flywheel attaching bolts. Torque the bolts to specification.
12. Install the inspection cover on the bottom front side of the flywheel housing.
13. Position the shift cable bracket to the transmission and install the attaching bolts.
14. Connect the shift cable to the manual lever at the transmission.
15. Install the vacuum modulator actuating rod and vacuum modulator into the case. Install the vacuum modulator retainer and secure with the attaching bolt. Torque the bolt to specifications.
16. Connect the vacuum line to the vacuum modulator.
17. Connect the oil cooler lines to the transmission case.
18. Connect the speedometer cable.
19. Connect the fluid filler tube to the oil pan.
20. Position the parking brake handle and brackets to the transmission case and secure with the attaching bolts.
21. Install the parking brake drum.
22. Connect the parking brake linkage.
23. Install the drive shaft, the center support bearing bracket and the coupling shaft. Connect the coupling shaft to the parking brake drum. Torque all bolts and nuts to specification.
24. Position the transmission access covers to the floor pan and secure with the attaching bolts. Reposition the floor covering. Install the door sill scuff plates and secure with the attaching screws.
25. Add enough automatic transmission fluid to the converter and transmission to bring the fluid level to the full mark on the dipstick.
26. Check the transmission, converter assembly and oil cooler lines for leaks.

CONTROL VALVE BODY

Removal

1. Place a drain pan under the transmission. Disconnect the filler tube from the transmission pan and allow the fluid to drain.
2. Remove the bolts and nuts securing the two rear engine supports to the crossmember. Remove the lower insulators and flat washers.
3. Place a jack under the transmission, then raise the transmission to take the weight off the crossmember.
4. Remove the oil pan and gasket.
5. Remove the oil filter retaining screw and remove the filter.
6. Remove the oil intake pipe (Fig. 11).
7. Remove the detent spring retaining bolt and remove the spring.
8. Remove the 18 control valve body attaching bolts and remove the valve body and the three attached tubes

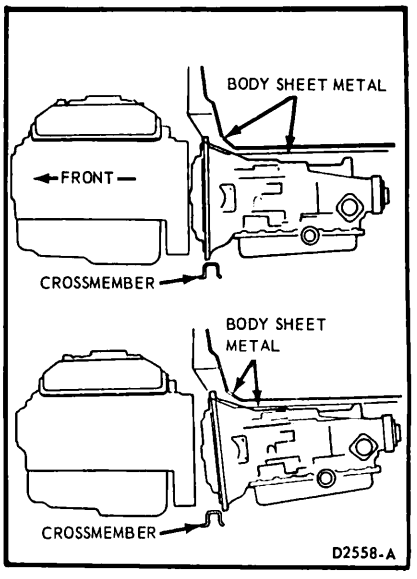

FIG. 7 Removing or Installing Automatic Transmission

from the case. **Be careful not to drop the selector valve out of the valve body.**

Installation

1. Install the governor feed tube, pressure tube and the first-reverse clutch tube in the valve body.
2. Install the control valve body by aligning the three tubes with the holes in the case. Install the valve body attaching bolts and tighten them evenly to 8-12 ft-lbs torque. Be sure the long 1/2-20 x 2 3/4 inch bolt is installed near the center of the valve body (Fig. 11).
3. Position the detent spring on the valve body, making sure the spring roller is centered on the selector lever. Install and tighten the attaching bolt to specification.
4. Install a new seal ring on the end of the intake pipe and install the pipe.
5. Position the oil filter on the intake pipe and install the attaching screw. Torque the screw to specification.
6. Place a new oil pan gasket on the transmission case and install the pan. Install the attaching screws and torque the screws evenly to specification.
7. Lower the transmission jack and remove it from under the vehicle.
8. Position the lower insulators and flat washers to the crossmember and install the rear support-to-crossmember bolts and nuts. Torque the bolts to specification.
9. Secure the fluid filler tube to the pan. Fill the transmission to the proper level with the specified fluid.

TRANSMISSION DRAIN AND REFILL

1. If the fluid is cold, operate the transmission until a normal operating temperature is reached.
2. Disconnect the filler tube from the transmission pan and allow the fluid to drain.
3. When the fluid has stopped draining, reconnect the filler tube and tighten the fitting securely.
4. Remove the dipstick and pour approximately ten quarts of transmission fluid into the transmission through the filler tube.
5. With the vehicle standing level, apply the parking brake and place the selector lever in N. Operate the engine at idle speed.
6. If the transmission fluid is cold, operate the transmission until normal operating temperatures (150 degrees to 200 degrees F) is reached.
7. When the engine and transmission have reached their normal operating temperatures, shift the selector lever through all the range positions to make sure that warm fluid is distributed throughout the transmission. Return the selector lever to N.
8. Check the fluid level on the dipstick. The safe operating level is between the ADD and FULL marks on the dipstick. If fluid level is low, add sufficient fluid to bring level to the FULL mark. If level is too high, drain excess fluid to proper level.

VACUUM MODULATOR

Removal

1. Disconnect the vacuum line from the vacuum modulator.
2. Remove the vacuum modulator retainer bolt and remove the retainer.
3. Remove the vacuum modulator and valve actuating rod from the case. Remove the seal ring from the modulator (Fig. 8).

Installation

1. Install the vacuum modulator actuating rod (Fig. 8) into the case. Be sure larger diameter is inserted first.
2. Install a new seal ring on the vacuum modulator. Lubricate the seal ring with oil-soluble grease and install the modulator into the case.
3. Rotate the modulator until the vacuum hose connector pipe faces directly forward. Then, install the retainer, with the bent tabs against the transmission, and secure with the attaching bolt. Torque the bolt to specification.
4. Connect the vacuum line to the vacuum modulator.

GOVERNOR

Removal

1. Remove the four governor cover-to-case attaching bolts (Fig. 8).
2. Remove the cover, cover gasket and governor from the case. Rotate the governor clockwise to disengage the drive gears.

Installation

1. Insert the governor assembly in the case.
2. Place a new gasket on the governor cover and install the cover (Fig. 8). Install and torque the cover attaching bolts to specification.

EXTENSION HOUSING REAR SEAL

Removal

1. On a one-piece drive shaft, disconnect the shaft from the yoke at the parking brake drum. On a two-piece drive shaft, disconnect the coupling shaft from the yoke at the parking brake drum, and then remove the center support bearing bracket. Move the forward end of the drive shaft out of the way.
2. Disconnect the parking brake linkage.
3. Remove the bolts securing the parking brake drum to the extension housing and remove the drum.
4. Remove the seal as shown in Figure 9.

Installation

1. Install a new extension housing seal using the tool shown in Figure 10.
2. Position the parking brake drum to the extension housing and install the attaching bolts. Torque the bolts to specification.

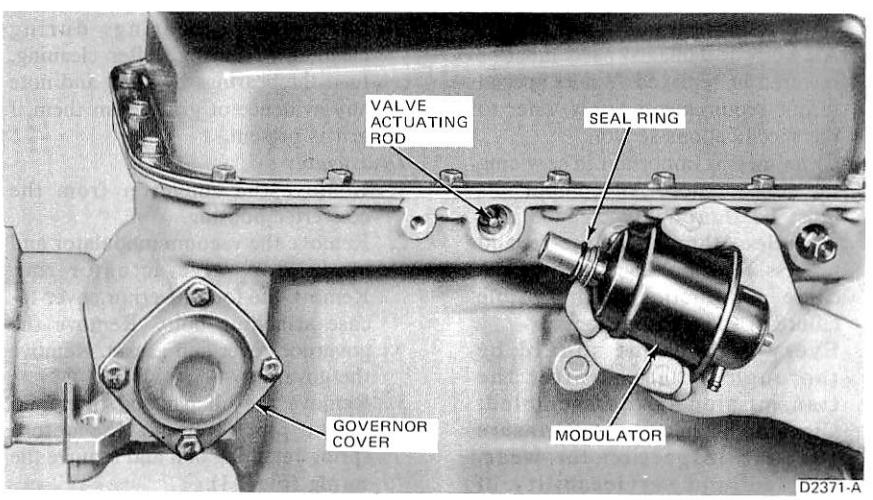

FIG. 8 Removing or Installing Vacuum Modulator

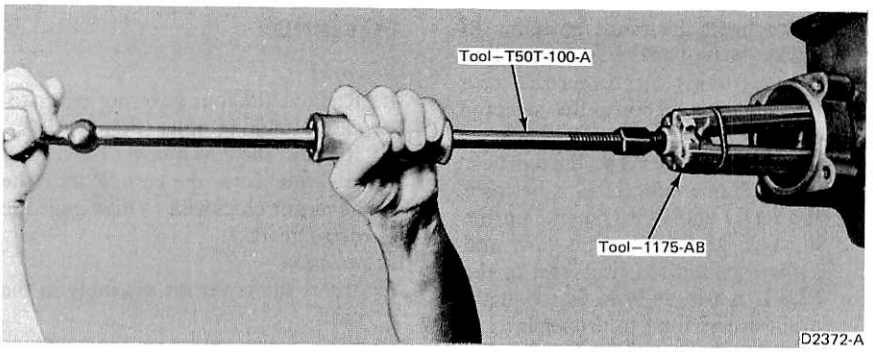

FIG. 9 Removing Extension Housing Seal

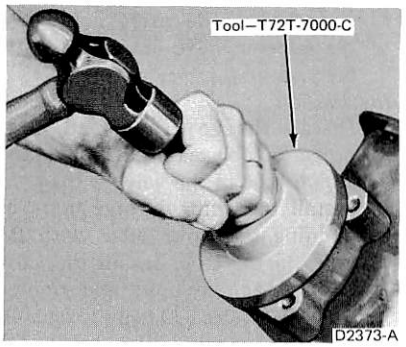

FIG. 10 Installing Extention Housing Seal

3. Connect the parking brake linkage.
4. Connect the drive shaft or the coupling shaft and center support bearing bracket. Torque the nuts and/or bolts to specification.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

1. Proper equipment must be available before disassembly is started. This equipment includes a suitable hoist of at least 1/4-ton capacity, proper hand tools and special tools, and a press.
2. Gaskets, lock wires, lock strips, and cotter pins should be discarded as they are removed. New parts of this type should always be installed.
3. Care must be used to avoid damage to transmission components during disassembly, cleaning, inspection, repair, and assembly operations. Nicks, and scratches caused by careless handling may cause fluid leakage or improper functioning and could result in transmission failure. All worn or damaged parts must be repaired or replaced. Where special torque requirements apply, refer to the specifications section.
4. Cleanliness is important in servicing the transmission. All components must be thoroughly cleaned and kept clean throughout the rebuild process. The presence of dirt can cause malfunction, and possible failure of the transmission.
5. Every component should be thoroughly cleaned after the transmission is disassembled. Cleaning is necessary to insure effective inspection for wear, damage, and serviceability of components.
6. Crocus cloth may be used to remove minor surface irregularities.
7. A soft wire (brass or copper) may be used to clean fluid passages. Always flush such passages thoroughly after cleaning.
8. If steam cleaning is used, dry the cleaned parts immediately with compressed air and apply a film of oil to prevent rusting. Never use lye or caustics which will corrode or etch metal surfaces.
9. Do not clean the lubricant from new bearings. Keep new bearings wrapped until they are to be installed. Soak bearings which have been in service, in dry cleaning solvent or mineral spirits paint thinner to loosen deposits of dirt. Do not spin the bearings during cleaning or drying. After cleaning, turn the bearings by hand and note any evidence of grit. Clean them if grit is present.

Disassembly

1. Remove the converter from the converter housing.
2. Remove the vacuum modulator and modulator valve actuator rod. Remove the four governor cover-to-case attaching bolts. Remove the governor cover and gasket. Remove the governor.
3. Remove the oil pan, oil filter and intake pipe. Remove the detent spring retaining bolt and remove the spring (Fig. 11).
4. Remove 18 control valve body attaching bolts. Lift the valve body and the three attached oil tubes from the transmission case (Fig. 11). **Be careful not to drop the selector valve out of the valve body.**
5. Remove the three oil tubes from the valve body. Remove the oil screen from the valve body, at the governor feed tube bore.
6. Using a magnet, remove the steel governor check valve ball from the channel in the transmission case (Fig. 12). Remove the center support anchor bolt and flat washer.
7. Remove nine bolts and lockwashers from the front support and two bolts and seals from opposite holes in the oil pump body. Use the tools shown in Fig. 13 to loosen the pump, then lift it out of the case.
8. Remove the two hook-type seal rings and thrust washer from the hub of the front support (Fig. 14).
9. Remove the front support gasket (Fig. 15). Lift the forward clutch and turbine shaft assembly out of the case. Remove the nylon thrust washer from the rear of the assembly.
10. Grasp the fourth clutch spring retainer and lift the clutch assembly out of the case (Fig. 16).
11. Remove the sun gear shaft (Fig. 17).
12. Remove the snap ring from the third-clutch back plate, using the tool shown in Figure 18, and remove the back plate. Remove the clutch plates (Fig. 17).

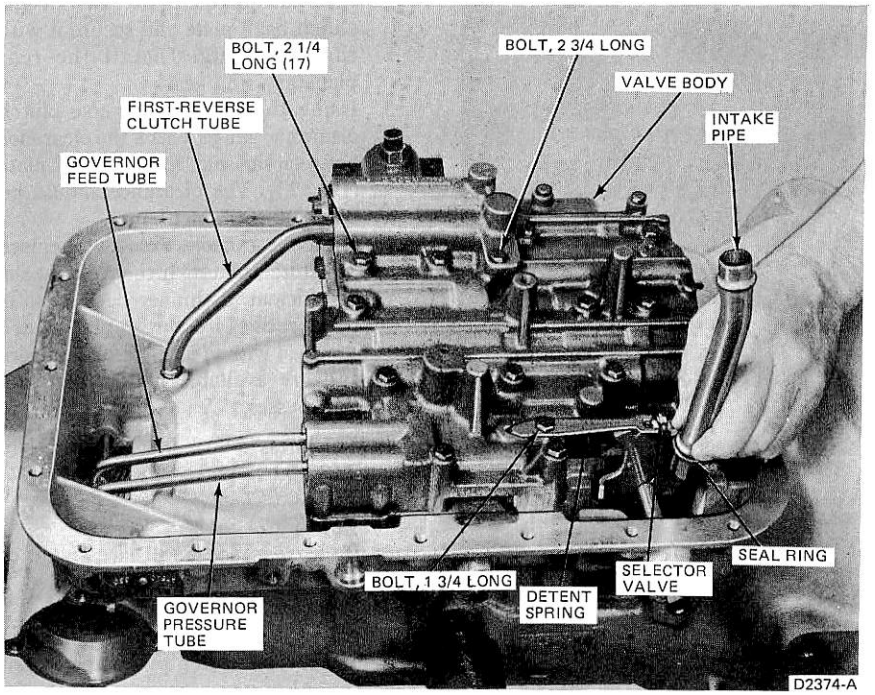

FIG. 11 Removing or Installing Oil Intake Pipe

13. Remove the center support snap ring using Tool T72T-7000-JJ. Remove the two hook-type seal rings from the center support hub. Install the center support lifting tool on the hub and carefully lift the support out of the case (Fig. 19).
14. Remove the thrust washer from the front of the planetary sun gear.
15. Remove the planetary gears and shaft as a unit. **If necessary, tap the end of the output shaft with a soft-faced hammer to loosen the assembly.**
16. Remove the governor and speedometer drive gears and spacer if they did not come out with the planetary gears and shafts assembly.
17. Using Tool T72T-7000-JJ, remove the snap ring securing the second-clutch in the transmission case. Remove the clutch plates and back plate.
18. Using Tool T72T-7000-JJ, remove the first and reverse clutch back plate snap ring and remove the back plate. Remove the rear planetary ring gear and clutch plates.
19. Compress the first and reverse clutch springs with the tool shown in Figure 20. Remove the snap ring. Remove the tool, spring retainer, piston return springs and piston. As the tool is released, guide the retainer spring to clear the snap ring groove. Remove the two lip-type seals from the piston grooves.
20. Remove the output shaft seal using the tools shown in Figure 9.
21. Remove the rear bearing snap ring and remove the bearing with the tools shown in Figure 21.

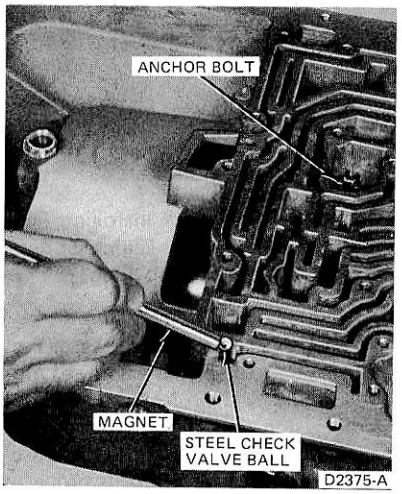

FIG. 12 Removing or Installing Governor Check Valve Ball

Assembly

1. Lubricate and install new inner and outer seal rings in the first and reverse clutch piston grooves. Position the inner seal protector

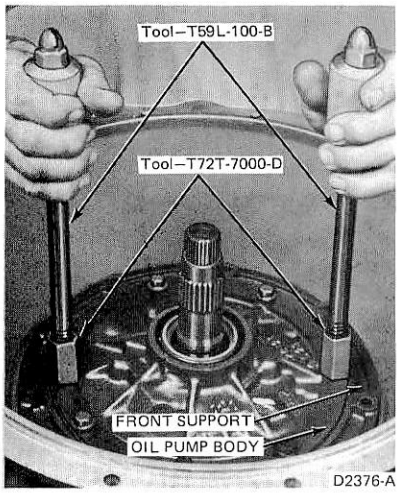

FIG. 13 Removing or Installing Oil Pump Assembly

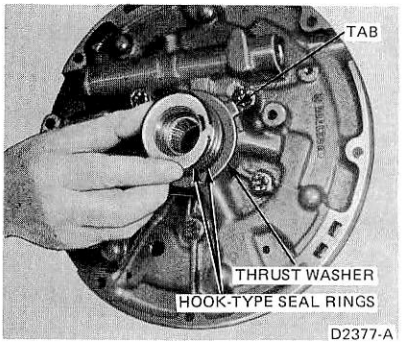

FIG. 14 Removing or Installing Front Support Seal Rings and Thrust Washer

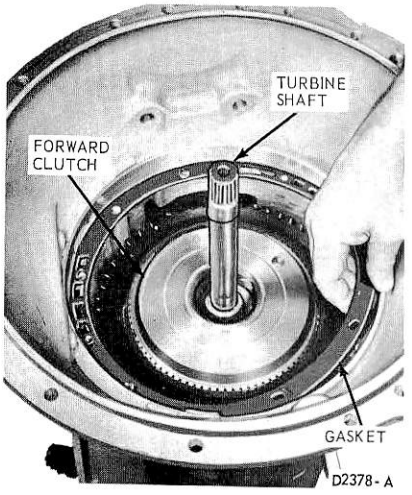

FIG. 15 Removing or Installing Front Support Gasket

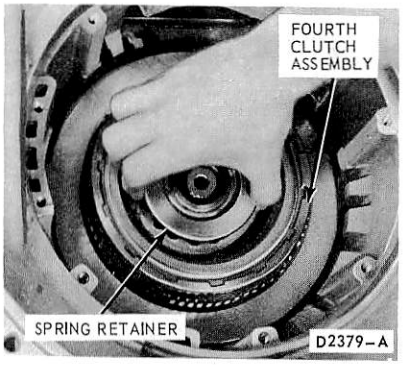

FIG. 16 Removing or Installing Fourth-Clutch Assembly

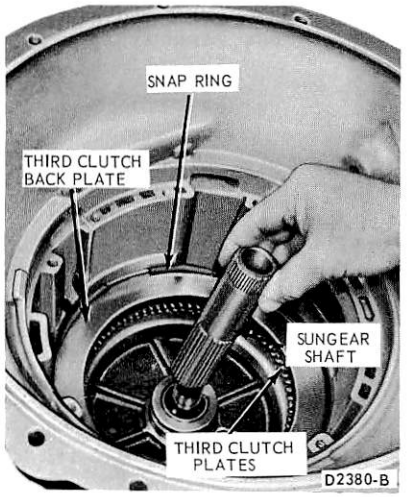

FIG. 17 Removing Sun Gear Shaft

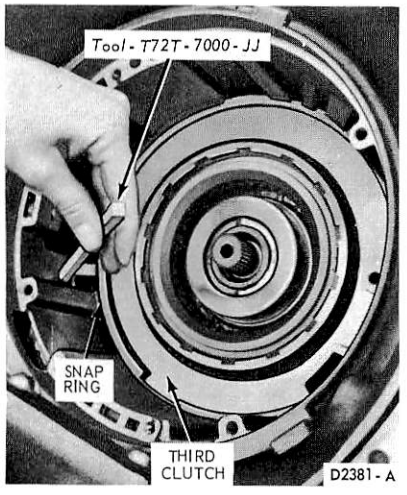

FIG. 18 Removing Third-Clutch Snap Ring

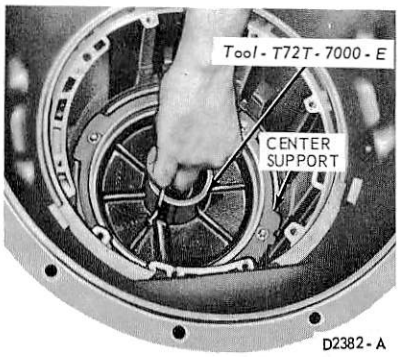

FIG. 19 Removing Center Support

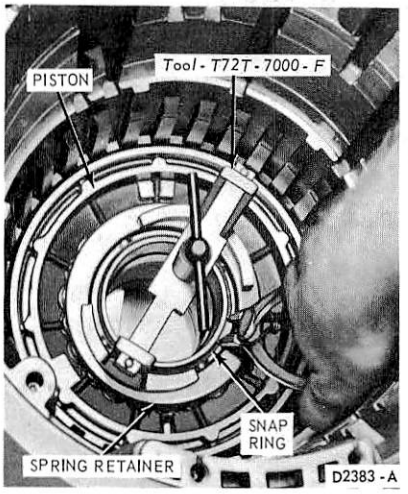

FIG. 20 Removing or Installing First and Reserve Clutch Spring Retainer Snap Ring

over the center hub in the case (Fig. 22). Insert the piston backward into the outer seal protector, then hold the piston and large seal protector and insert as a unit into the case. When the seal protector is properly seated, push the piston into place making sure the tang on the piston is seated in the slot in the case.

2. Position the piston return springs in the piston recesses. Check to be sure the springs are properly aligned and place the spring retainer on the springs. Place the snap ring on the spring retainer.
3. Install the spring compressor tool (Fig. 20) and compress the springs until the spring retainer clears the snap ring groove. Install the snap ring and remove the tool.
4. Install the first and reverse clutch plates alternately starting with an external-tanged plate. Install the clutch back plate and secure it with the snap ring. Install the rear planetary ring gear.
5. Using the first and reverse clutch clearance gauge, check the clearance between the snap ring and back plate (Fig. 23). The clearance should be 0.0405-0.1005 inch.
6. If the clearance is excessive, replace the clutch plates. If the clearance is insufficient, a thinner back plate is required. The back plates are stamped with identification numbers and are available in the following thicknesses:

Thickness	Identification No.
0.683-0.693 inch	1
0.647-0.657 inch	2
0.611-0.621 inch	3

If the clearance is still excessive after new clutch plates have been installed, a thicker back plate is required.

7. Align the internal splines of the first and reverse clutch plates and install the planetary gears and shafts assembly into the transmission case. **Be sure the rear planetary ring gear splines engage all of the internal splined plates of the clutch.**
8. Install the second clutch back plate in the transmission case, then install the clutch plates alternately starting with an internal splined plate (Fig. 24). Install the snap ring.
9. Before installing the center support in the transmission case, remove the third clutch piston from the assembly.
10. Using the center support lifting tool, lower the center support into the transmission case (Fig. 19). Be sure the tapped hole in the support is aligned with the bolt hole in the bottom of the case. Remove the tool.
11. Install the flat washer and center support anchor bolt (Fig. 12). **Do not tighten the bolt at this time.**
12. Install the center support compressor tool as shown in Figure 25. Use two of the oil pump retaining bolts to secure the tool.
13. Tighten the compressor tool bolt to 8-10 ft-lbs torque.
14. Using the snap ring selection gauge, check the snap ring groove clearance (Fig. 25). The gauge has four lugs of different color and thicknesses. Try all four lugs into the groove. The thickest lug which will enter the groove indicates the color code of the snap ring required. Selective snap rings are available as follows: Thickness

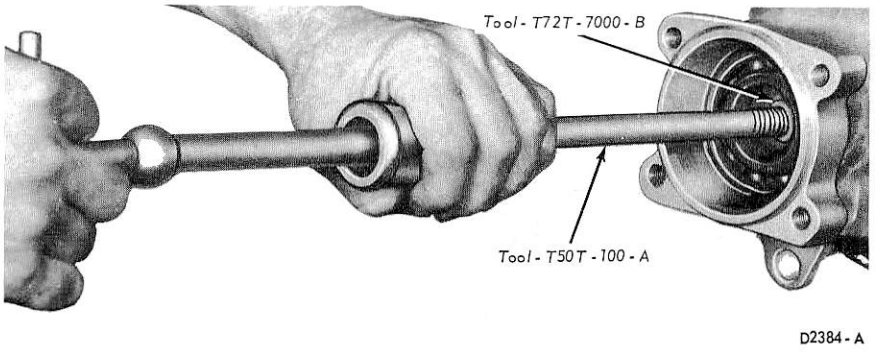

FIG. 21 Removing Output Shaft Rear Bearing

Gauge and Snap Ring Color Code

0.150-0.154	Blue
0.154-0.157	Yellow
0.157-0.160	Green
0.160-0.164	Red

After selecting the correct snap ring, remove the tool.

15. Install the third clutch piston in the center support assembly and secure it with the snap ring selected above.
16. Install the sun gear shaft. Be sure the long splined end is installed toward the rear of the transmission.
17. Install the sun gear shaft retainer tool on the transmission mainshaft (Fig. 26).
18. Position the transmission with the output shaft up.
19. Install the governor and speedometer drive gears on the output shaft. Using a soft drift, tap against the speedometer drive gear to seat both the governor and speedometer gears in the case.
20. Position the spacer selection gauge tool firmly against the output shaft and speedometer drive gear (Fig. 27). Loosen the thumbscrew and push the sliding member against the rear bearing snap ring groove. Tighten the thumbscrew. Be sure the two pins protruding from the back face of the tool are aligned in a single spline of the output shaft to keep the tool straight for an accurate measurement.
21. Remove the gauge, and using a depth micrometer, measure the distance as shown in Figure 27. This dimension will determine which selective spacer to use. The spacers are serviced as follows:

Micrometer Dimension	Identification
1.0003-1.0138	1 Groove
1.0138-1.0273	2 Grooves

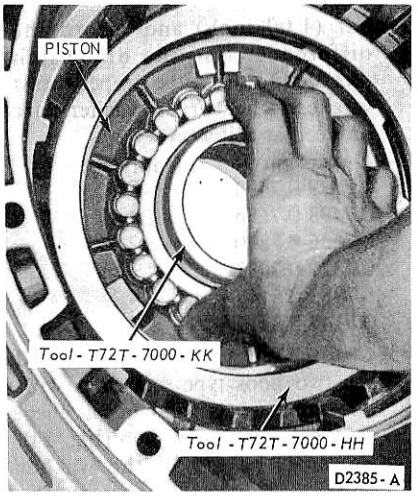

FIG. 22 Installing First and Reverse Clutch Piston

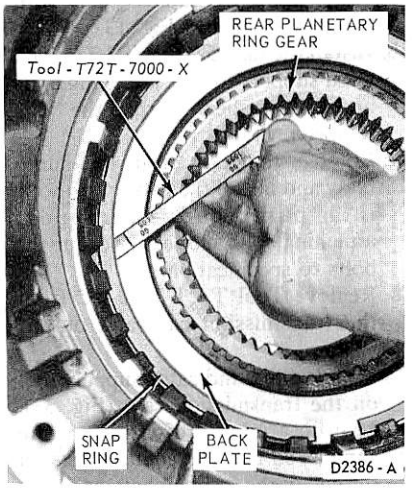

FIG. 23 Checking First and Reverse Clutch Clearance

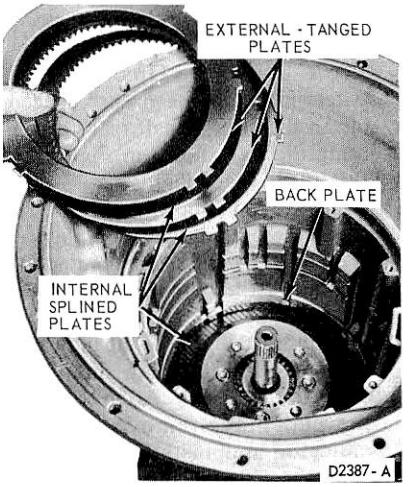

FIG. 24 Installing Second Clutch Plates

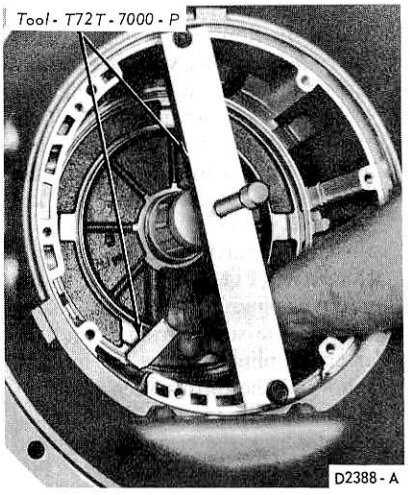

FIG. 25 Check Snap Ring Groove Clearance

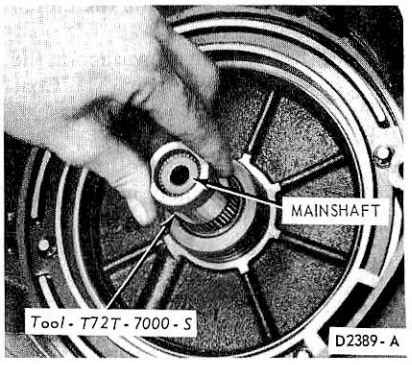

FIG. 26 Installing Sun Gear Shaft Retainer Tool

1.0273-1.0408	3 Grooves
1.0408-1.0543	4 Grooves
1.0543-1.0678	5 Grooves
1.0678-1.0813	6 Grooves

22. After installing the proper spacer, install the output shaft rear bearing using the tool shown in Figure 28. Install the snap ring.
23. Using the tools shown in Figure 29, check the output shaft end play.
24. With the dial indicator contacting the end of the output shaft, set the indicator at zero. Pull the output shaft upward and note the indicator reading. The end play should be 0.003 to 0.042 inch. After checking the end play, remove the dial indicator and install two 1/2-13 bolts through the bore of the tool and into the case. Tighten the bolts to 5-8 ft-lbs torque.
25. Reposition the transmission, mainshaft up, and remove the sun gear shaft retainer tool.
26. Install the third clutch clutch plates alternately starting with an external-tanged plate. Be sure the single tang on the plates engage the single slot in the case. Install the clutch back plate and secure it with the snap ring. **Be sure to use the back plate marked with a 2.**
27. Install the fourth clutch assembly in the case (Fig. 16). Be sure the internal splines of the clutch housing engages the sun gear shaft and the external splines engage the internal splines of the third clutch plates.
28. Using the third clutch clearance gauge, check the clearance between the snap ring and back plate (Fig. 30). The clearance should be 0.029-0.119 inch. If the clearance is excessive, replace the clutch plates. Refer to the wear limit chart in the Specification Section for the clutch plate dimensions.
29. Place the nylon thrust washer on the forward clutch hub (Fig. 31). Coat the washer with oil-soluble grease to hold it in place.
30. Install the forward clutch and turbine shaft assembly in the case.
31. Rotate the forward clutch assembly one or two revolutions, while pushing it downward.
32. Using the tools shown in Figure 32, measure the distance from the top of the gauge bar to the thrust washer surface of the clutch housing. Subtract the thickness of the gauge bar (1.00 inch) and record the difference. Use the dimension recorded to select the proper thrust washer. The thrust washers are serviced as follows:

Dimension	Identification
0.7329-0.7493	0
0.7493-0.7656	1
0.7656-0.7820	2
0.7820-0.7983	3
0.7983-0.8147	4
0.8147-0.8311	5

33. Coat the selected thrust washer and the two hook-type seal rings with oil-soluble grease and install them on the front support hub (Fig. 14). Be sure the tab of the washer engages the cast recess in the support.
34. Install the front support gasket, aligning the bolt holes in the gasket with those in the case (Fig. 15).
35. Install the oil pump assembly with the tools shown in Fig. 13.
36. Install the nine 5/16-18 x 1 3/4 inch front support-to-case attaching bolts and lock washers. Torque the bolts to specification.
37. Remove the tools from the pump body and install the two 5/16-18 x 1 inch pump body-to-support attaching bolts and seals. Torque the bolts to specification.
38. Remove Tool T72T-7000-CC from the transmission case and output shaft.
39. Mount a dial indicator support tool on the transmission case (Fig. 33). Mount a dial indicator on the support so that the contact rests on the end of the turbine shaft. Measure the turbine shaft end play. The desired end play is 0.0053-0.0337

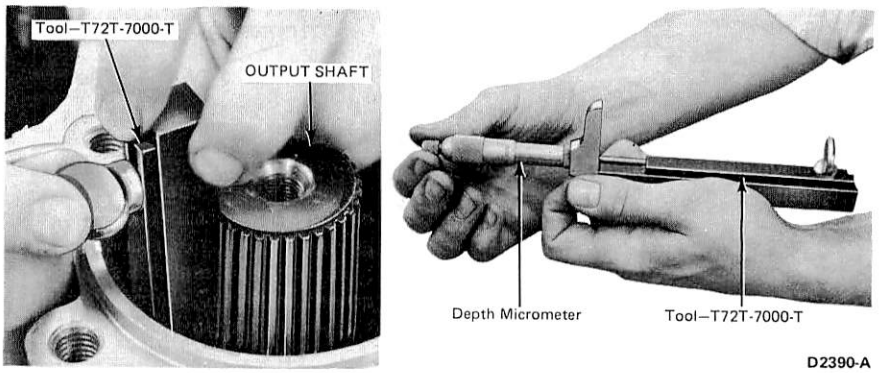

FIG. 27 Rear Bearing Spacer Measurement

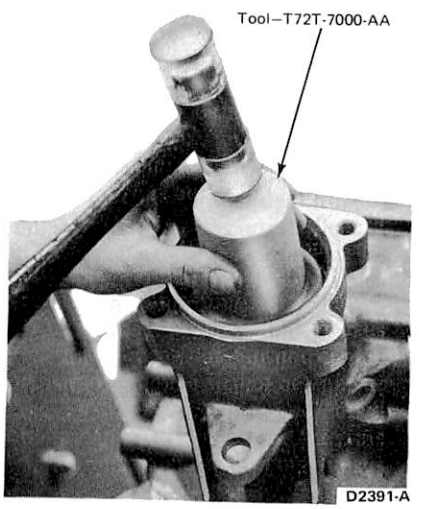

FIG. 28 Installing Rear Bearing

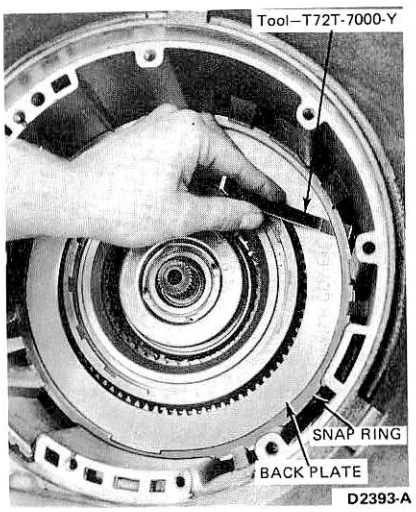

FIG. 30 Checking Third Clutch Clearance

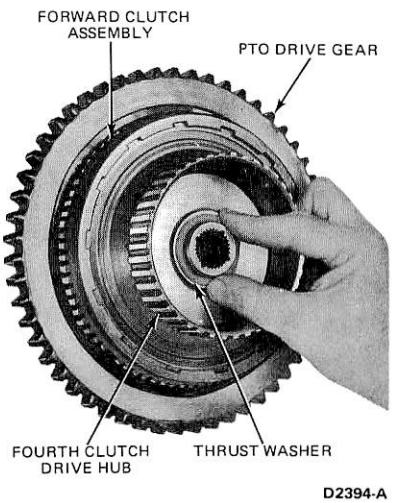

FIG. 31 Installing Forward Clutch Hub Thrust Washer

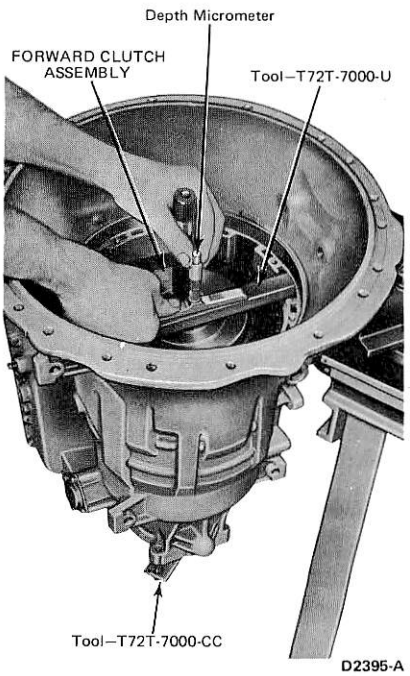

FIG. 32 Front Thrust Washer Measurement

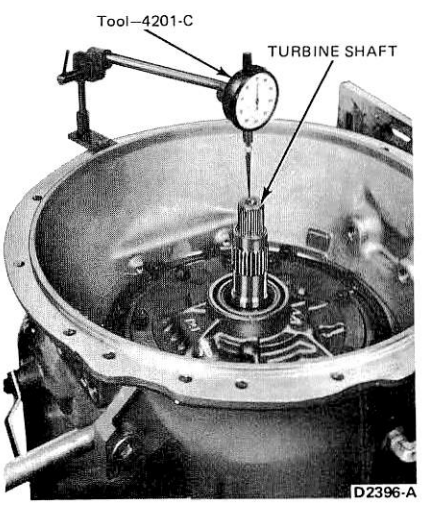

FIG. 33 Measuring Turbine Shaft End Play

inch. Remove the tool.

40. Install the output shaft oil seal (Fig. 10). Refer to Removal and Installation for the installation procedures.
41. Install the steel governor check valve ball into the transmission case (Fig. 12).
42. Tighten the center support anchor bolt (Fig. 12) to 39-46 ft-lbs torque.
43. Position the control valve body in the case. **Be careful not to drop the selector valve out of the valve body.**
44. Install the governor oil screen into the feed tube opening of the valve body. Install the governor feed tube, pressure tube and the first-reverse clutch tube in the valve body.
45. Lift the valve body and install the three tubes into their respective bores in the case (Fig. 11).
46. Position the detent spring on the valve body and install the 1/4-20 x 1 3/4 inch bolt (Fig. 11).
47. Hold the detent spring roller in the center of the selector lever and tighten the bolt to 8-12 ft-lbs torque.
48. Install the remaining control valve body attaching bolts and tighten them evenly to 8-12 ft-lbs torque. Be sure the long 1/4-20 x 2 3/4 inch bolt is installed near the center of the valve body.
49. Install a new seal ring on the end of the intake pipe and install the pipe.
50. Position the oil filter on the intake pipe and install the attaching screw. Torque the screw to specification.
51. Place a new oil pan gasket on the transmission case and install the pan. Install the attaching screws and torque the screws evenly to specification.
52. Insert the governor assembly in the case. Place a new gasket on the governor cover and install the cover. Install the four attaching bolts and torque the bolts to specification.
53. Install the vacuum modulator actuating rod into the case. Be sure the larger diameter is inserted first.
54. Install a new seal ring on the vacuum modulator. Lubricate the seal ring with oil-soluble grease and install the modulator into the case.
55. Rotate the modulator until the vacuum hose connector pipe faces directly forward. Then, install the retainer, with the bent tabs against the transmission, and secure with the attaching bolt. Torque the bolt to specification.
56. Install the converter assembly.
57. Install the transmission in the vehicle.

CONTROL VALVE BODY

Disassembly

1. Remove the manual valve (Fig. 34).
2. Remove the three vacuum modulator valve body bolts and remove the valve body. Remove the spacer plate.
3. Remove the priority valve, spring and valve stop from the control valve body.
4. Before removing the vacuum modulator valve, note the slot in the adjusting ring in which the retaining pin is seated. Then, hold the adjusting ring against the spring pressure and remove the pin. Remove the adjusting ring, valve stop, spring valve, spring and vacuum modulator valve (Fig. 34).
5. Remove the eight bolts from the trimmer cover and remove the cover. **The cover is spring loaded and must be held while the bolts are removed.**
6. Removal of the cover will expose the four trimmer valve stops. Remove these stops from the valve body. Also remove a trimmer spring, plug and valve from each of the trimmer valve bores.
7. Remove the 2-3 and 1-2 relay valve retaining pins from the valve body. **The spring spacers are spring loaded and must be held while the retaining pins are being removed.**
8. Remove the 2-3 relay valve spring

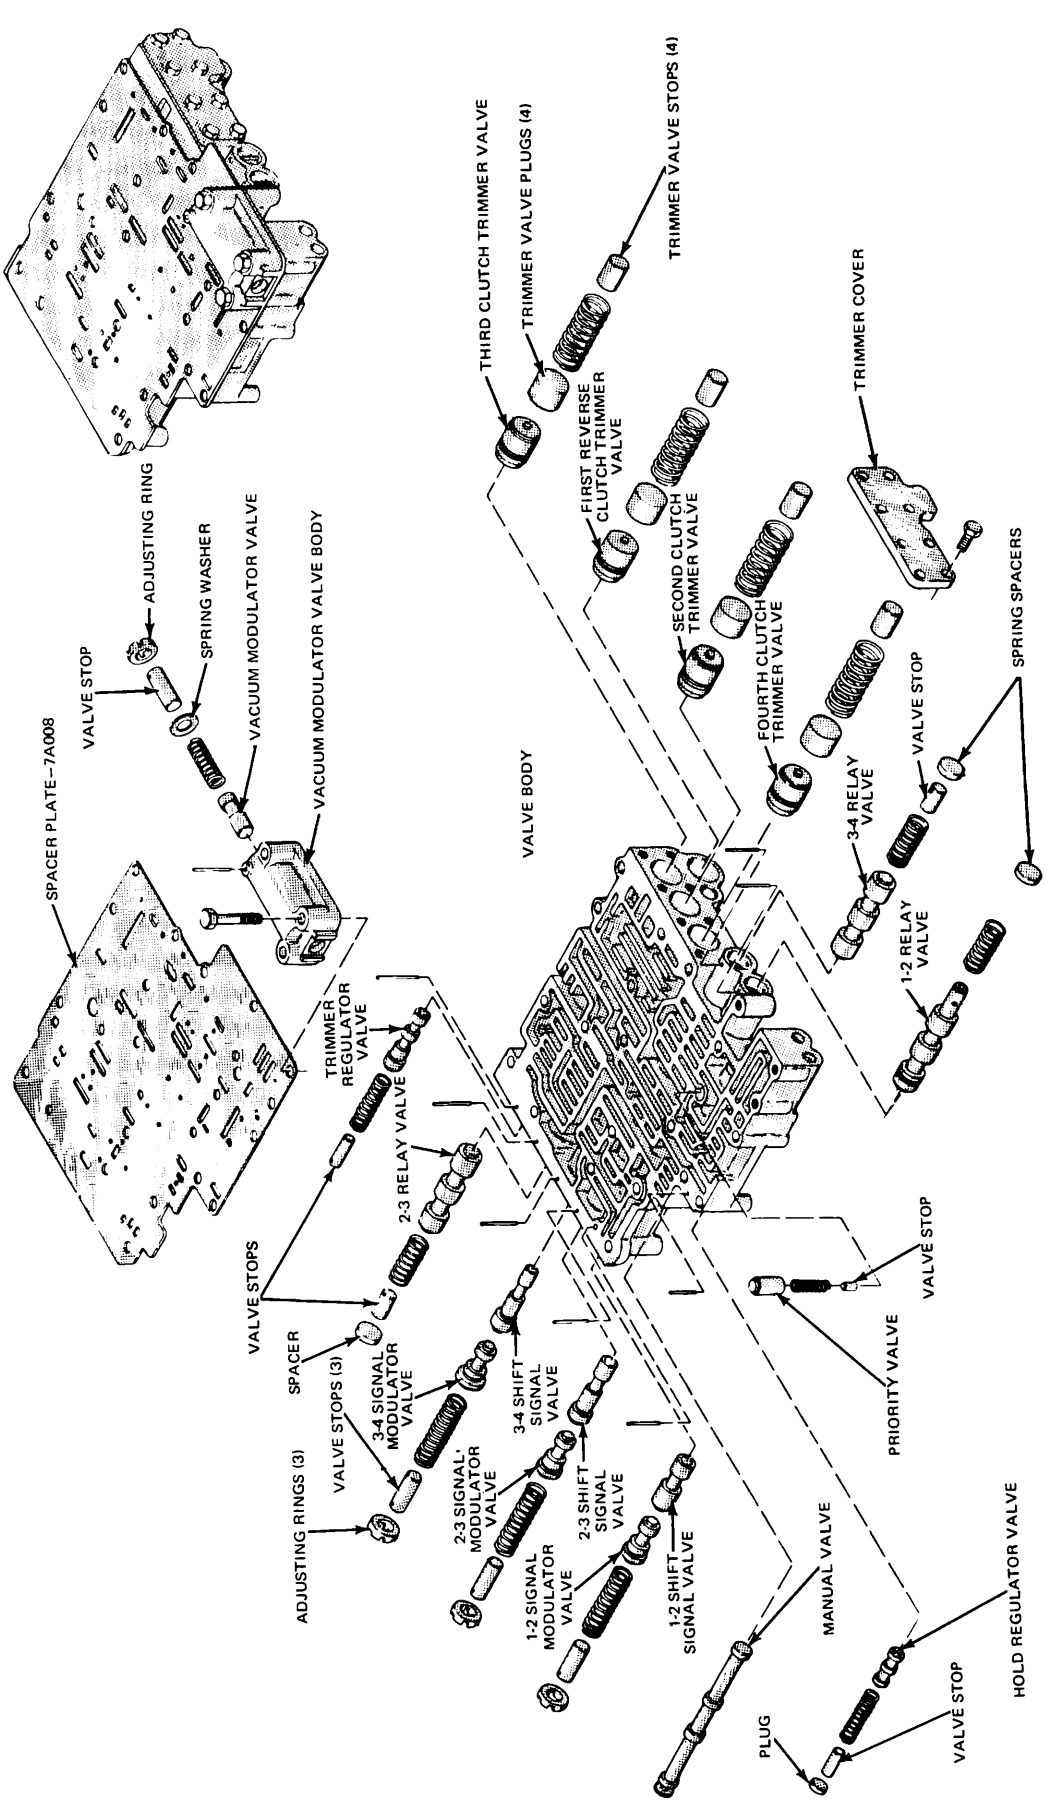

FIG. 34 Control Valve Body Disassembled

spacer, valve stop, spring and valve.
9. Remove the 1-2 relay valve spring spacer, spring and valve.
10. Remove the hold regulator valve retaining pin from the valve body. **The valve plug is spring loaded and must be held while the retaining pin is being removed.**
11. Remove the hold regulator valve plug, valve stop, spring and valve.
12. Remove the 1-2, 2-3 and 3-4 modulator and signal valve retaining pins from the valve body (Fig. 34). **The adjusting rings are spring loaded and must be held while the retaining pins are being removed. Also, note the slots in the adjusting rings in which the pins are seated.**
13. Remove an adjusting ring, valve stop, spring, modulator valve and signal valve from each of the modulator and signal valve bores.
14. Hold the 3-4 relay valve spring spacer against the spring pressure and remove the retaining pin.
15. Remove the 3-4 relay valve spring spacer, valve stop, spring and valve.
16. Hold the trimmer regulator valve stop against the spring pressure and remove the retaining pin.
17. Remove the trimmer regulator valve stop, spring and valve.
18. All the valve body parts should be thoroughly cleaned in cleaning solvent and dried with compressed air. All passages must be completely free of dirt and obstructions. Use a soft bristle brush. **Do not use abrasives or scraping tools.** After cleaning, place the parts on clean paper and cover with paper to keep the dust out.
19. Inspect all the parts closely for wear, breaks, cracks, burrs, and dirt. Burrs may be removed with a soft abrasive stone. **Do not destroy the sharp edges of valves. The valves are designed with sharp edges to prevent them from sticking in their bores.**
20. Inspect all the springs and check them for free length. Correct performance of the transmission depends upon the good condition of springs. **Refer to specifications section for valve body spring identification and specifications.**
21. Before assembly, try all the valves in their bores. When parts are clean and dry, the valves should move in their bores by their weight only. Do not force them into the bores.

Assembly

Check the position of all components, configuration of all valves and plugs and the identification of all springs before installation. Refer to the spring chart in the Specification Section for positive spring identification.

1. Install the trimmer regulator valve, spring and valve stop (Fig. 34). Align the valve stop pin hole with the pin hole in the valve body and install the retaining pin.
2. Install the 3-4 relay valve, spring, valve stop and spring spacer into the valve body. Depress the spring spacer and install the retaining pin.
3. Place the 3-4, 2-3 and 1-2 shift signal valves, modulator valves, springs and valve stops into their respective bores in the valve body. Install the adjusting rings. Align each previously used adjusting ring slot with the pin holes in the valve stop and valve body and install the retaining pins. **When installing adjusting rings, without replacing valve springs, the retaining pins must align with the slots previously used. If a valve spring has been replaced, align the intermediate height slot with the retaining pin. Use the adjusting tool shown in Figure 35 for adjusting the rings.**
4. Place the hold regulator valve, spring, valve stop and plug in the valve body. Depress the plug and install the retaining pin.
5. Place the 1-2 relay valve and spring in the valve body. Install the spring spacer and secure with the retaining pin.
6. Place the 2-3 relay valve, spring and valve stop in the valve body. Install the spring spacer and secure with the retaining pin.
7. Place the trimmer valves, plugs, springs and valve stops into their respective bores in the valve body (Fig. 34). Secure the trimmer cover to the body with the eight attaching bolts. Torque the bolts to specification.
8. Place the vacuum modulator valve, spring, spring washer and valve stop in the vacuum modulator valve body. Install the adjusting ring. If the valve spring was not replaced, align the previously used adjusting ring slot with the pin holes in the valve stop and valve body and install the retaining pin. If the valve spring was replaced, align the intermediate height slot with the retaining pin. Use the adjusting tool shown in Figure 35 for adjusting the ring.
9. Place the priority valve stop, spring and valve in the valve body.
10. Depress the priority valve against its spring and install the spacer plate.
11. Position the vacuum modulator valve body on the spacer plate and secure with the three attaching bolts. Torque the bolts to specification.
12. Install the manual valve.

SELECTOR SHAFT

1. Remove the selector shaft retaining pin and locknut (Fig. 36).
2. Hold the selector lever and carefully slide the selector shaft from the case. Remove the selector lever.
3. Use the tools shown in Figure 37 and remove the seal from the case.
4. Coat the inside diameter of the new seal with oil soluble grease and the outside diameter with a non-hardening sealant.
5. Install a new seal as shown in Figure 38.
6. Slide the selector shaft through the seal and into the transmission case.

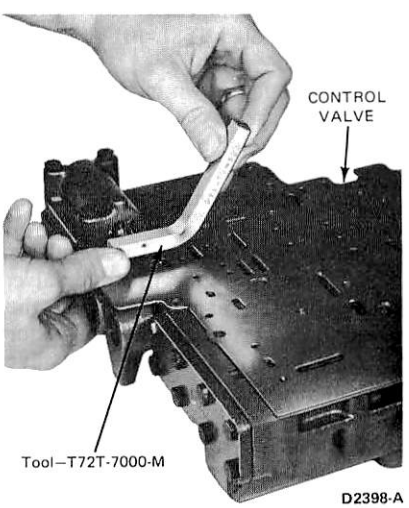

FIG. 35 Adjusting Vacuum Modulator Valve Ring

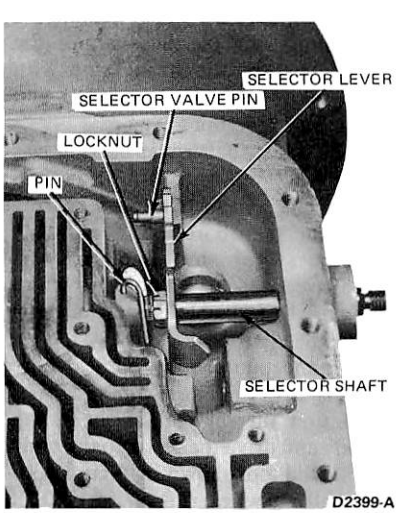

FIG. 36 Selector Shaft and Lever

7. Position the selector lever on the shaft and install the locknut. Torque the nut to specification. Install the retaining pin.

OIL PUMP

Disassembly

1. Remove the large seal ring from the O.D. of the front support (Fig. 39).
2. Remove eight bolts and seals from the oil pump body and six bolts from the front support assembly. Separate the oil pump body from the front support.
3. Remove the drive and driven gears from the pump body.
4. Remove the large seal ring from the O.D. of the pump housing.
5. Remove the oil seal from the pump body using Tools 1175-AB and T50T-100-A.
6. If the stator shaft bushing and/or front support roller bearing are worn or damaged, remove them using Tools T58L-101-A and T50T100-A.
7. Use the tool shown in Figure 40 to press the main pressure regulator valve spring stop against the spring pressure and remove the retainer ring from the front support assembly (Fig. 40).
8. Remove the main pressure regulator valve spring stop, spring and valve.
9. Remove the retaining pin from the small end of the pressure regulator valve bore and remove the valve plug.

Assembly

1. Place the valve plug in the small end of the pressure regulator valve bore and secure with the retaining pin (Fig. 39).
2. Place the main pressure regulator valve, spring and spring stop in the front support assembly. Install the retaining ring on the shaft of the tool. Depress the spring stop with the tool shown in Figure 40 and install the retaining ring.
3. If the stator shaft roller bearing was removed, use the tool shown in Figure 41 and install a new bearing into the shaft bore.
4. If the stator shaft bushing was removed, use the tool shown in Figure 42 and install a new bushing into the shaft bore.
5. Coat the pump body oil seal bore with non-hardening sealant. Position the oil seal in the pump body and drive the seal into the body with the tool shown in Figure 43.
6. Install a new seal ring on the O.D. of the pump body (Fig. 39).
7. Place the pump gears in the pump body.

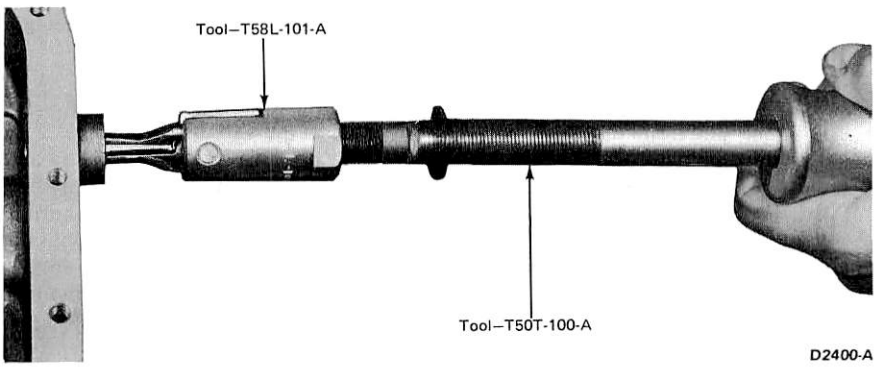

FIG. 37 Removing Selector Shaft Oil Seal

8. Position the front support on the pump body and install the 13 attaching bolts. Torque the bolts to specification.
9. Install a new seal ring on the O.D. of the front support.

FORWARD CLUTCH AND TURBINE SHAFT

Disassembly

1. Place the forward clutch and turbine shaft assembly on a work bench, with the shaft up. Remove the hook-type seal ring from the shaft (Fig. 44).
2. If equipped with a power take-off drive gear, remove the snap ring securing the drive gear to the forward clutch housing. To remove the snap ring, fabricate eight 5 inch lengths of 5/32 inch drill rod ground to a point at one end. Then, locate the snap ring gap between the I.D. of the PTO gear and the O.D. of the forward clutch housing (Fig. 45). Insert one of the pins, point first, into the flat area opposite the snap ring gap. Push the pin point between the O.D. of the snap ring and the PTO gear. Insert the remaining pins in the same manner, working alternately from each side of the first pin toward the snap ring gap as shown in Figure 45. When all the pins are inserted, tap the gear downward and off the clutch housing.
3. Remove the snap ring securing the fourth clutch driving hub to the forward clutch housing and remove the hub.
4. Remove the forward clutch hub.
5. Remove the needle bearing and needle bearing races from the hub of the forward clutch housing.
6. Remove the clutch plates.
7. Place the clutch assembly in a press with the spring retainer up. Compress the piston spring retainer with the tool shown in Figure 46.

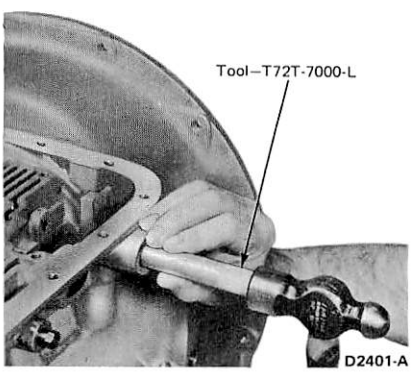

FIG. 38 Installing Selector Shaft Oil Seal

Remove the snap ring, tool, spring retainer, piston return springs and piston. Remove the inner and outer seal rings from the piston grooves.

8. Remove the seal ring from the forward clutch housing (Fig. 44).
9. Check the forward clutch housing ball to make sure it moves freely in the housing.

Assembly

1. Place the forward clutch housing assembly on a bench with the shaft down.
2. Install the clutch housing seal ring (Fig. 44). **Be sure the seal is centered in its groove with the lip of the seal facing downward.**
3. Place the clutch piston on the work bench with the return spring side up. Install the inner and outer seal rings. Install the piston inner seal protector on the hub of the clutch housing. Insert the piston backward into the outer seal protector, then hold the piston and large seal protector and insert as a unit into the housing. When the seal protector is properly seated in the housing, push the piston into place (Fig. 47). Remove the tools. **Be sure the seals are centered in their grooves with the lip of the seals facing downward.**
4. Install the piston into the forward

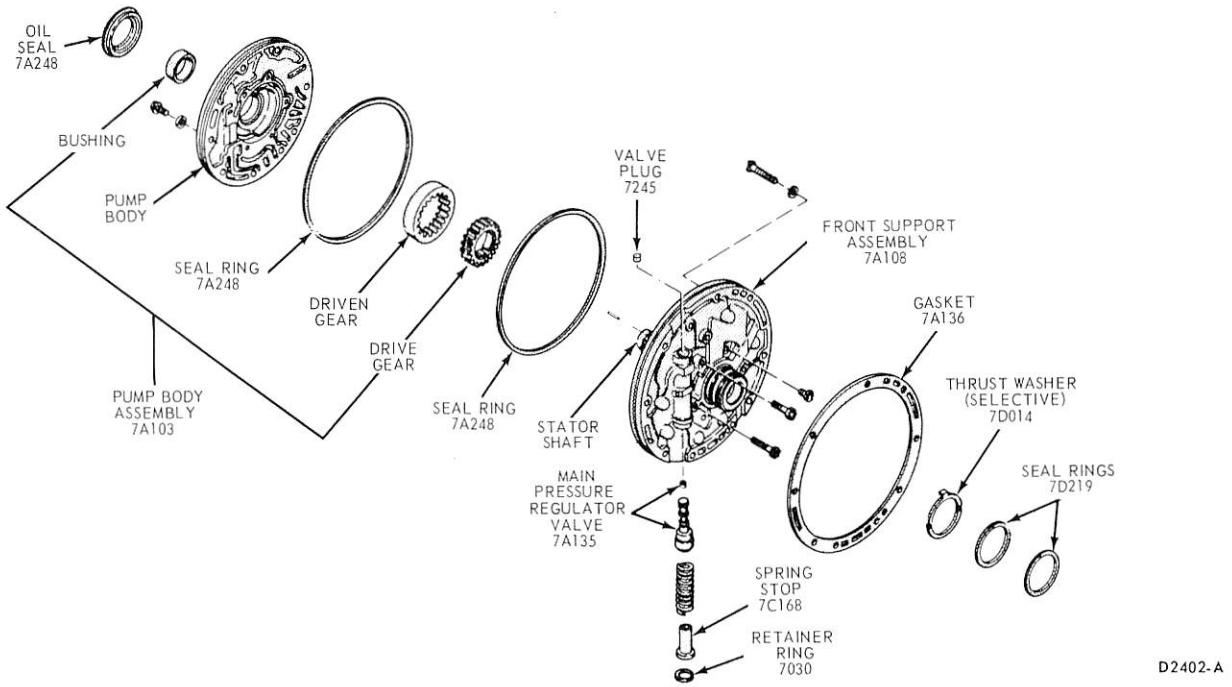

FIG. 39 Oil Pump Disassembled

clutch housing, making sure it bottoms in the housing. **Do not install the piston return springs at this time.**

5. Install the clutch plates alternately starting with an external-tanged plate.
6. Install the fourth clutch hub in the clutch housing and secure with the snap ring.
7. With the forward clutch clearance gauge, check the clutch running clearance between the driving hub and clutch pack (Fig. 48). This clearance should be 0.0765-0.1125 inch. The clutch driving hub should be held up firmly against the snap ring as the clearance is checked.
8. If the clearance is not within the specified limits, replace the clutch plate(s), as required, to obtain the desired clearance. Refer to the wear limit chart in the Specification Section to determine the plate(s) which should be replaced. If the clutch housing or driving hub has been replaced, it may be necessary to select a piston of different thickness.
9. Repeat steps 5, 6 and 7 above until the clearance is within the specified limits. Then, remove the driving hub snap ring and remove the hub and clutch plates.
10. Position the piston return springs on the piston spring guide bosses. Place the spring retainer on the springs with the recessed side of the retainer toward the springs.
11. Place the clutch assembly in a press and compress the spring retainer with the tool shown in Fig. 46. Install the snap ring. Make sure the snap ring is fully seated in the groove.
12. Place the flat needle bearing race on the forward clutch housing hub. Then, install the needle bearing and the remaining needle bearing race. Retain the bearing and races with oil soluble grease.
13. Install the forward clutch hub in the clutch housing (Fig. 44).
14. Install the clutch plates alternately starting with an external-tanged plate.
15. Install the fourth clutch driving hub in the clutch housing and secure with the snap ring (Fig. 44).
16. If equipped with a power take-off drive gear, install the snap ring in the O.D. of the forward clutch housing snap ring groove. Place the PTO gear, chamfered I.D. side down, onto the clutch housing. Compress the snap ring into the groove of the clutch housing and push the PTO gear down over the snap ring. Be sure the gear is properly positioned and the snap ring is fully seated.

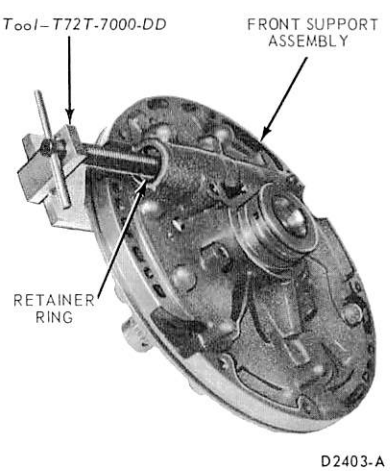

FIG. 40 Removing Or Installing Main Pressure Regulator Valve

17. Install the hook-type seal ring on the turbine shaft.

FOURTH CLUTCH

Disassembly

1. Place the fourth clutch assembly on a bench with the snap ring facing up.
2. Remove the snap ring securing the clutch back plate in the housing and remove the back plate and clutch plates (Fig. 49).

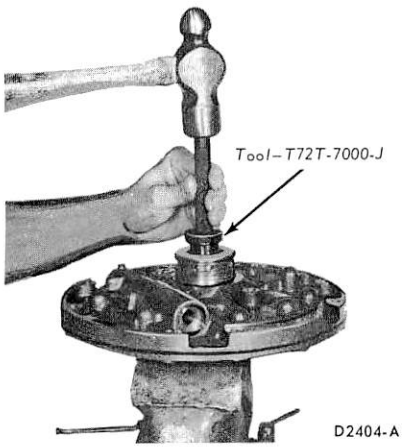

FIG. 41 Installing Stator Shaft Roller Bearing

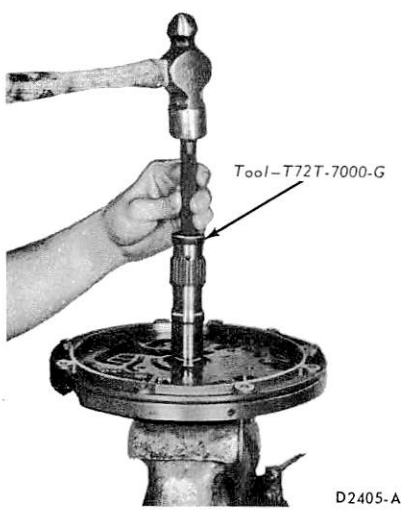

FIG. 42 Installing Stator Shaft Bushing

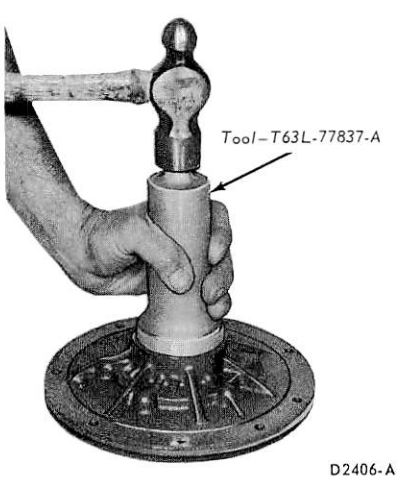

FIG. 43 Installing Oil Pump Seal

3. Place the fourth clutch assembly in a press with the spring retainer up. Compress the piston spring retainer with the tool shown in Figure 50. Remove the snap ring, tool, spring retainer, piston return springs and piston. Remove the seal ring from the O.D. of the piston.
4. Remove the seal ring from the clutch housing inner hub groove (Fig. 49). Check the groove thoroughly for burrs and rough spots.

Assembly

1. Place the fourth clutch housing on a bench with the open end up.
2. Install the clutch housing inner hub seal ring (Fig. 49). **Be sure the seal is centered in its groove with the lip of the seal facing downward.**
3. Place the clutch piston on the work bench with the return spring side up. Install the seal ring on the O.D. of the piston. **Be sure that the lip of the seal is facing downward.**
4. Install the piston into the fourth clutch housing using the tools shown in Figure 51. Install the piston inner seal protector on the hub of the clutch housing. Install the piston backward into the piston outer seal protector, then hold the piston and outer seal protector and insert as a unit into the housing. When the seal protector is properly seated in the housing, push the piston into place (Fig. 51). Remove the tools. **Do not install the piston return springs at this time.**
5. Install the clutch plates alternately starting with an external-tanged plate.
6. Install the back plate in the clutch housing and secure with the snap ring.
7. With the fourth clutch clearance gauge, check the clearance between the back plate and clutch pack (Fig. 52). This clearance should be 0.0625-0.1125 inch. The clutch back plate should be held up firmly against the snap ring as the clearance is checked.
8. If the clearance is not within the specified limits, replace the clutch plate(s), as required, to obtain the desired clearance. Refer to the wear limit chart in the Specification Section to determine the plate(s) which should be replaced. If the clutch housing or back plate has been replaced, it may be necessary to select a piston of different thickness.
9. Repeat steps 5, 6 and 7 above until the clearance is within the specified limits.
10. Position the piston return springs on the piston spring guide bosses. Place the spring retainer on the springs with the recessed side of the retainer toward the springs.
11. Place the clutch assembly in a press and compress the spring retainer with the tool shown in Figure 50. Install the snap ring. Make sure the snap ring is fully seated in the groove.

CENTER SUPPORT

Disassembly

1. Remove the second and third clutch pistons from the center support assembly (Fig. 53).
2. Remove the retainer washers from the piston pin bosses and remove the spring retainers and piston return springs.
3. Remove the inner and outer seal rings from each piston.
4. If the center support bushing is worn or damaged, replace the bushing with the tools shown in Figure 54. Mark the center support hub so that the notch in the new bushing is located in the same position in the center support as the notch in the discarded bushing.

Assembly

1. Place the second and third clutch pistons on a bench with the piston return spring sides up.
2. Place the piston return springs into each piston. Place the spring retainers on the springs. Depress the spring retainers and start new self-locking retainer washers on the piston pin bosses.
3. Before installing the piston seal rings, install the pistons in the center support assembly. The pistons should bottom in the center support before the spring retainers touch the outside diameter of the support. With the tangs on the spring retainers aligned with the slots of the center support, push the retainer washers on the piston pin bosses until the spring retainers are properly seated.
4. Remove the pistons from the center support assembly. Apply oil-soluble grease to the piston inner and outer seal ring grooves and install the seal rings. **Be sure the seal ring lips are facing toward the center support.**
5. Secure the slotted portion of the second clutch pack compressing tool in a vise and stack the second clutch plates alternately starting with a steel plate. Place the second clutch piston on the stacked plates and

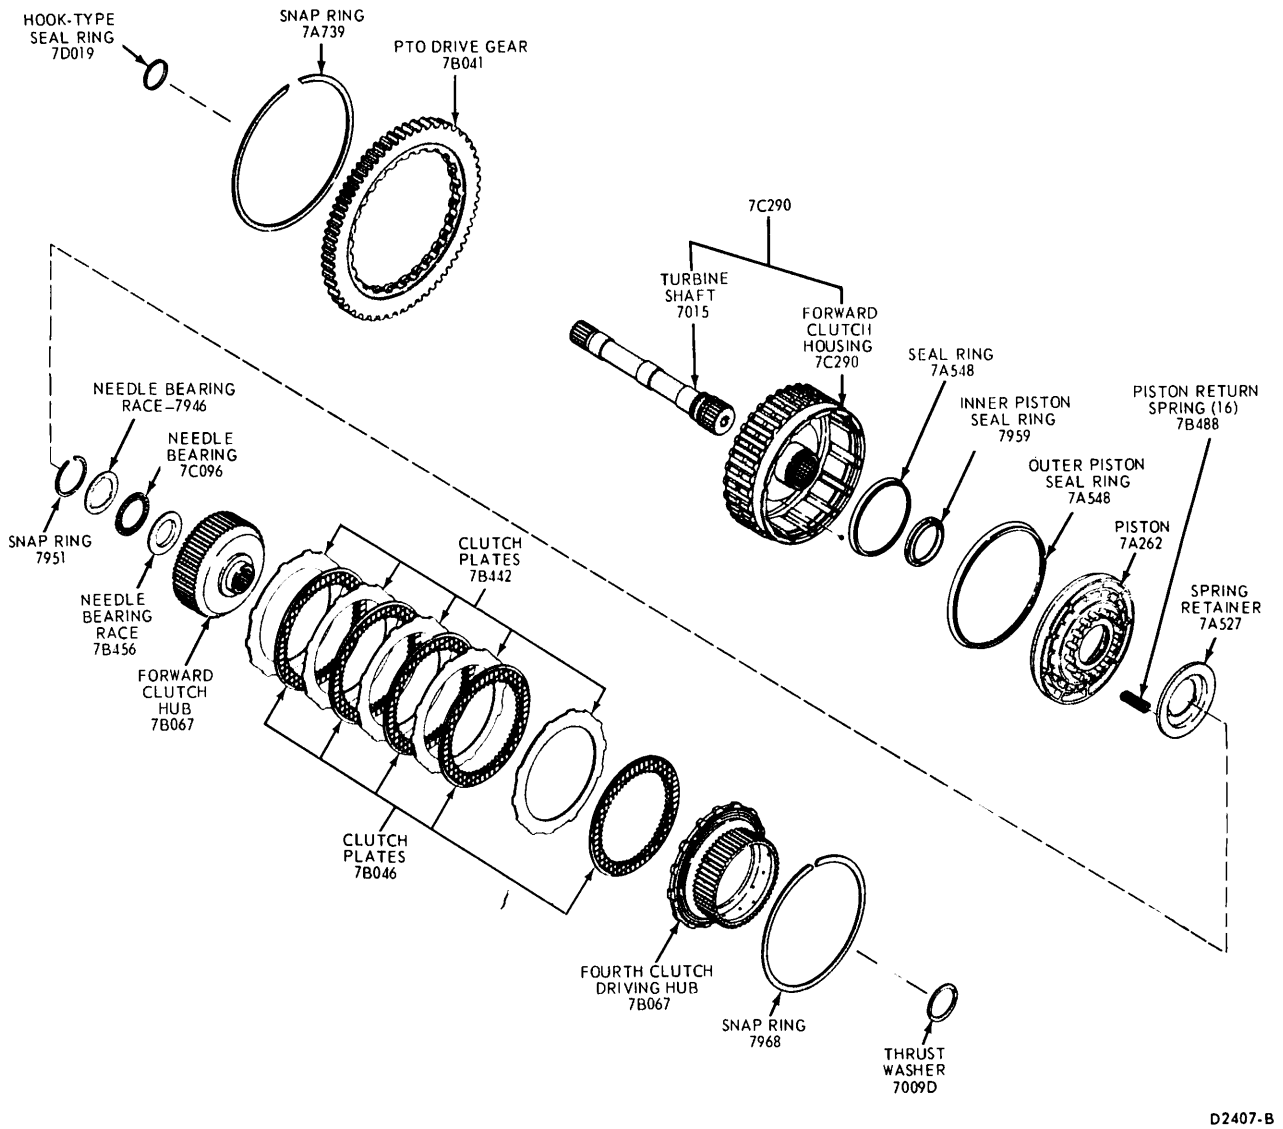

FIG. 44 Forward Clutch Disassembled

install the upper portion of the tool as shown in Figure 55. Torque the center bolt to 30-40 in-lbs. While the force is being applied, measure the distance at each end of the tool from the top of clutch pack to the shoulder below the outer piston seal ring groove (Fig. 55). This distance should be 1.4905-1.5165 inch if the second clutch back plate is stamped with a number 1. If the identification number on the back plate is stamped with a 2, the distance should be 1.5165-1.5425 inch.

6. If the distance is not within the specified limits, replace the clutch plate(s), as required, to obtain the desired measurement. Refer to the wear limit chart in the Specification Section to determine the plate(s) which should be replaced.
7. Apply a light coat of oil-soluble grease on the second and third clutch piston seal rings and install the pistons in the center support assembly using the tool shown in Fig 56. Install the piston backward into the tool and lower the piston and tool onto the center support. When the tool seats itself on the center support, push the piston into place (Fig. 56). Be sure the tangs on the spring retainers are aligned with the slots in the center support.
8. Install the two hook-type seal rings on the center support.

PLANETARY GEARS AND SHAFTS

Disassembly

1. Place the planetary gears and shafts assembly on its side on a work bench and remove the front planetary sun

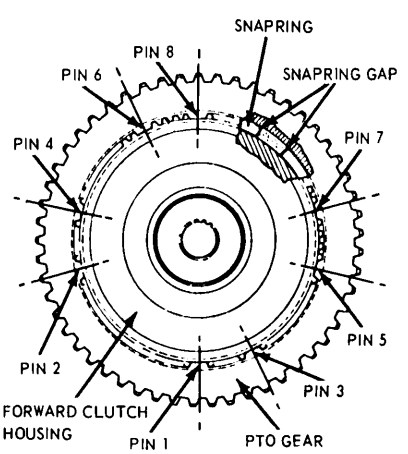

FIG. 45 Removing Power Take-Off Drive Gear

gear, carrier and selective thrust washer. Remove the larger thrust washer from the center planetary carrier assembly (Fig. 57).
2. Remove the front planetary ring gear snap ring and remove the ring gear, center planetary carrier, sun gear and thrust washer.
3. Remove the transmission mainshaft, center planetary ring gear and rear planetary sun gear as a unit.
4. Remove the needle bearing and race from the output shaft.
5. Remove the center planetary ring gear snap ring and remove the ring gear.
6. Remove the spiral retainer ring securing the rear planetary sun gear to the transmission mainshaft and remove the sun gear.
7. Push the output shaft toward the rear planetary ring gear and remove the snap ring. Remove the output shaft and bearing.
8. Remove the spiral retainer ring securing the rear planetary ring gear to the rear planetary carrier and remove the ring gear and two spacer washers.
9. Remove the snap ring securing the planetary connecting drum to the rear planetary carrier and separate the drum from the carrier.
10. The output shaft pin and bearing need not be removed unless replacement is necessary.
11. If the sun gear shaft and/or output shaft bushings are worn or damaged, remove them using Tools T58L-101A and T50T-100-A.
12. If the front planetary carrier bushing is worn or damaged, replace the bushing with the tools shown in Fig. 58.

Assembly

1. If the output shaft bushing was removed, install a new bushing using the tool shown in Figure 59.
2. If the sun gear shaft bushings were removed, install new bushings using the tool shown in Figure 60.
3. Install the output shaft pin and bearing, if they were removed (Fig. 57).
4. Position the rear planetary carrier assembly into the planetary connecting drum and secure it with the snap ring.
5. Position a spacer washer and the rear planetary ring gear on the hub of the rear planetary carrier. Place the remaining spacer washer on the planetary ring gear and secure the assembly with the spiral retainer ring.
6. Slide the output shaft and bearing into the rear planetary carrier and secure with the snap ring.
7. Install the rear planetary sun gear on the transmission mainshaft and secure it with the spiral retainer ring.
8. Install the center planetary ring gear on the rear planetary sun gear and secure with the snap ring.
9. Coat the needle bearing and race with grease and place them on the end of the output shaft. Be sure the race is positioned against the shaft.
10. Slide the small end of the mainshaft, with its attached parts, into the output shaft.
11. Grease and install the thrust washer on the end of the rear planetary sun gear. Install the center planetary sun gear, with the large diameter against the thrust washer.
12. Slide the center planetary carrier assembly into the planetary connecting drum.
13. Grease and install the large thrust washer on the front planetary carrier hub.
14. Install the front planetary carrier assembly on the center planetary sun gear.
15. Place the planetary gears and shafts in a holding fixture and install the tool shown in Figure 61. Use a 1/2-20 bolt (output shaft flange bolt) to apply pressure to the rear bearing and planetary carrier. Tighten the bolt to 30 ft-lbs torque.
16. Using a depth micrometer, measure the depth of the center planetary sun gear and front planetary carrier as shown in Figures 62 and 63. The difference between these measurements will determine which selective thrust washer to use. Selective thrust washers are stamped with identification numbers and are available in the following thicknesses:

Thickness	Identification No.
0.071-0.090 inch	1
0.090-0.109 inch	2
0.109-0.128 inch	3

After selecting the correct thrust washer, remove the front planetary carrier from the planetary gears and shaft assembly. Remove the tool from the output shaft.
17. Position the front planetary ring gear into the planetary connecting drum and secure it with the snap ring (Fig. 57).
18. Reinstall the front planetary carrier on the center planetary sun gear.
19. Grease and install the thrust washer, previously selected, on the center planetary sun gear.
20. Install the front planetary sun gear in the front planetary carrier assembly.

DESCRIPTION

TRANSMISSION

The Transmatic Drive is a hydraulically operated automatic transmission with six forward gear ratios and one reverse gear ratio. Figure 1 shows the location of the converter, gear train and most of the internal parts used in the transmission.

The transmission consists basically of a torque converter, a planetary gear train, and a hydraulic control system for shifting gears (Fig. 2).

An oil cooler, located in the vehicle radiator and connected to the transmission by tubing, cools the transmission fluid. A warning light, located on the instrument panel beneath the speedometer, indicates overheated fluid.

Two SAE regular-duty power takeoff openings are located at the sides of the transmission housing.

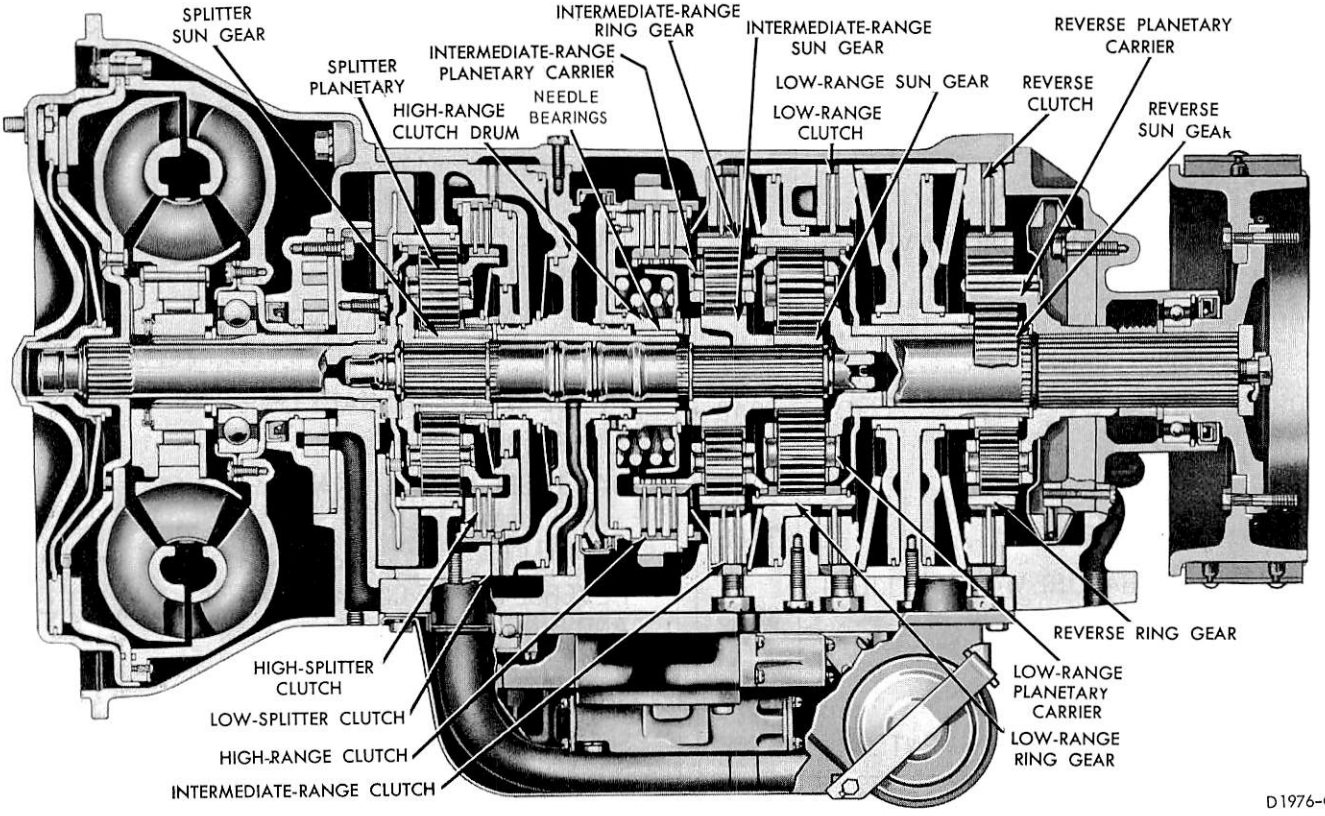

FIG. 1 Transmission Gear Train—Typical

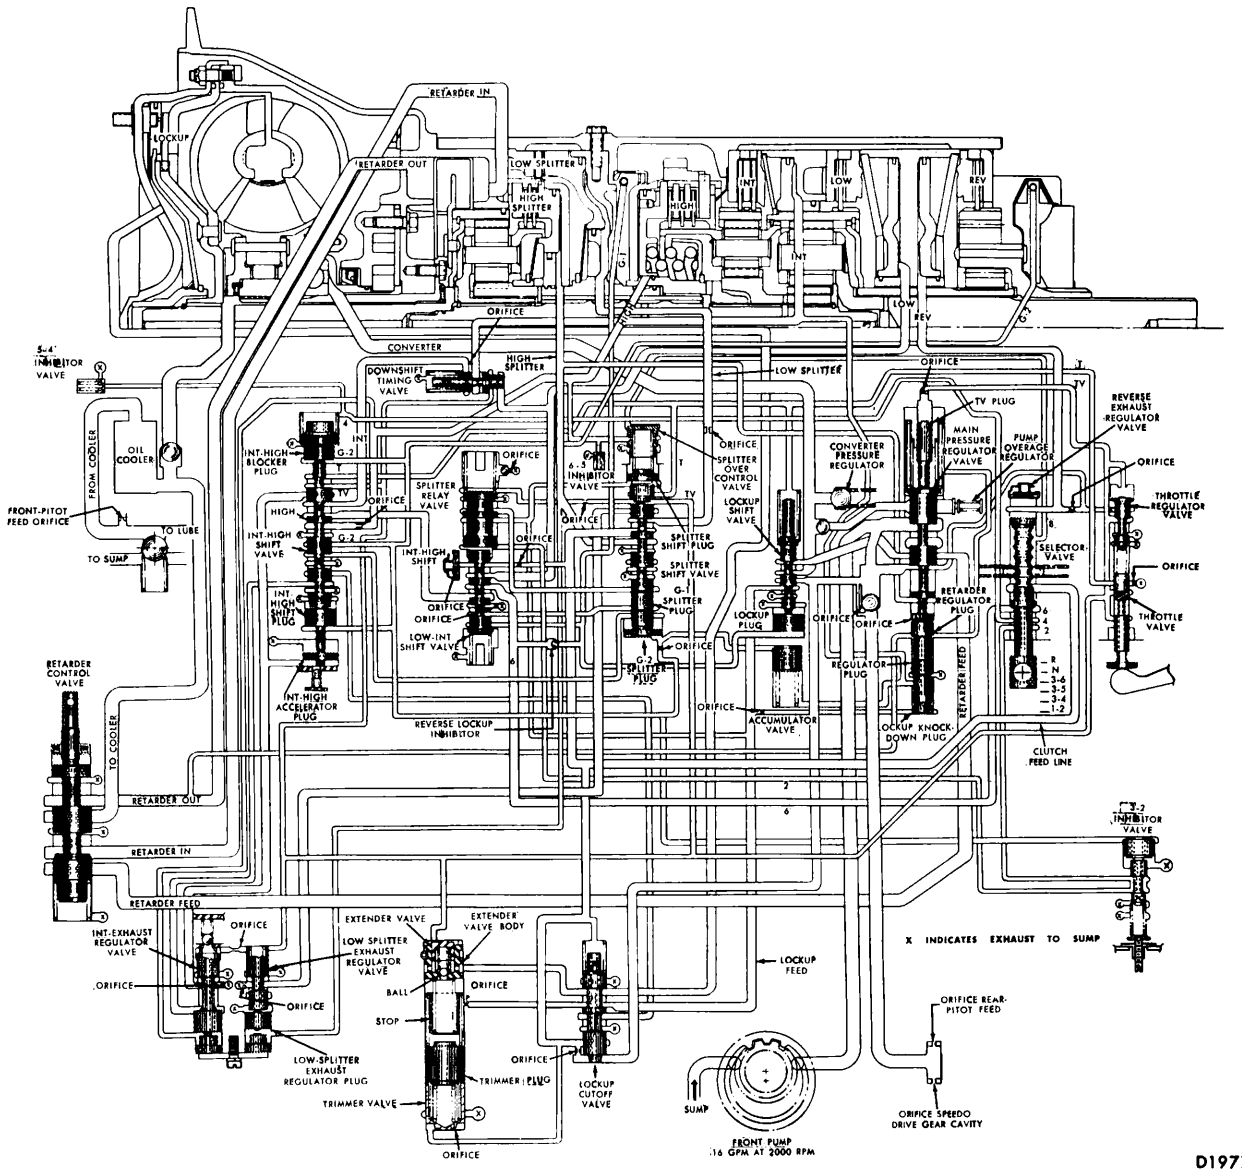

FIG. 2 Hydraulic Control System—Typical

TESTING

When diagnosing transmission problems, refer to the Truck Diagnosis Manual for the detailed information on the items that could be causing the problem.

TRANSMISSION FLUID LEVEL CHECK

1. With the vehicle standing, level, apply the parking brake, and place the range selector lever in N. Start the engine.
2. If the transmission fluid is cold, operate the transmission until normal operating temperature (150 degrees to 200 degrees F) are reached. **Do not operate the hydraulic retarder to warm the transmission fluid. Operating the hydraulic retarder when the vehicle is not moving will aerate the fluid, making an accurate fluid level check impossible.**
3. When the engine and transmission have reached their normal operating temperatures, move the selector lever through all the range positions to make sure that warm fluid is distributed throughout the transmission.
4. With the hand throttle, adjust the engine to idle speed with the selector lever at N.
5. Clean around the transmission fluid dipstick cap before removing the dipstick.
6. Twist the dipstick counterclockwise to unlock the cap from the tube. Pull the dipstick out of the tube, wipe it clean, and insert it back into the tube. On a C-Series truck, the dipstick can be removed through the opening in the panel behind the seat back cushion with the cab in its normal position.
7. Remove the dipstick again and check the fluid level. If necessary, add transmission fluid to raise the fluid level to the FULL mark on the dipstick. **If the fluid level is more than 5/16 inch above the FULL**

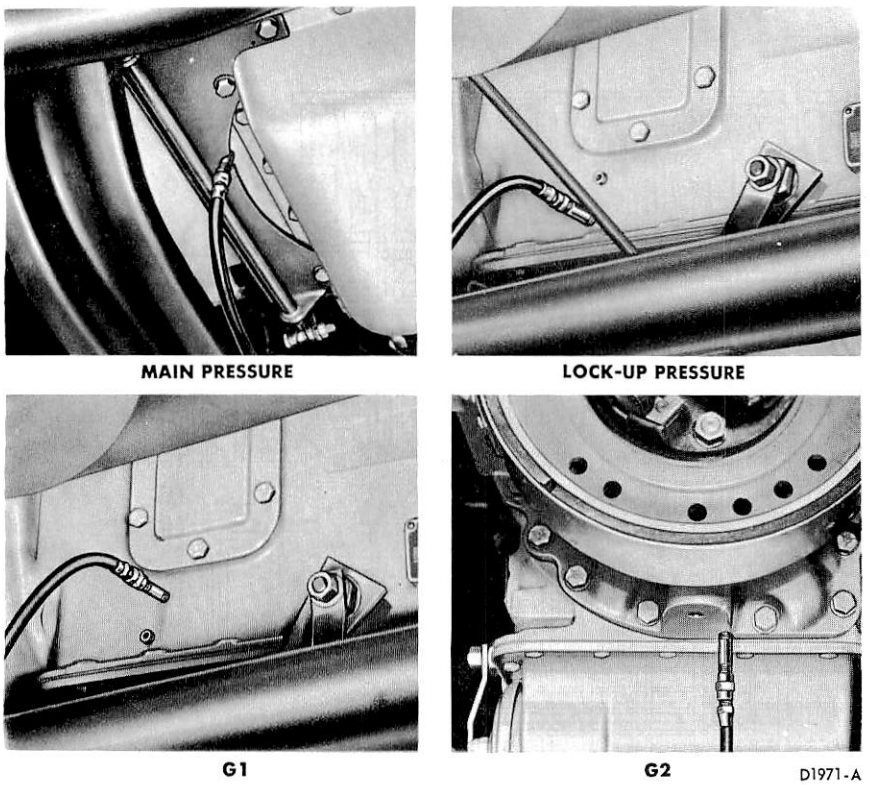

FIG. 3 Typical Fluid Pressure Checks

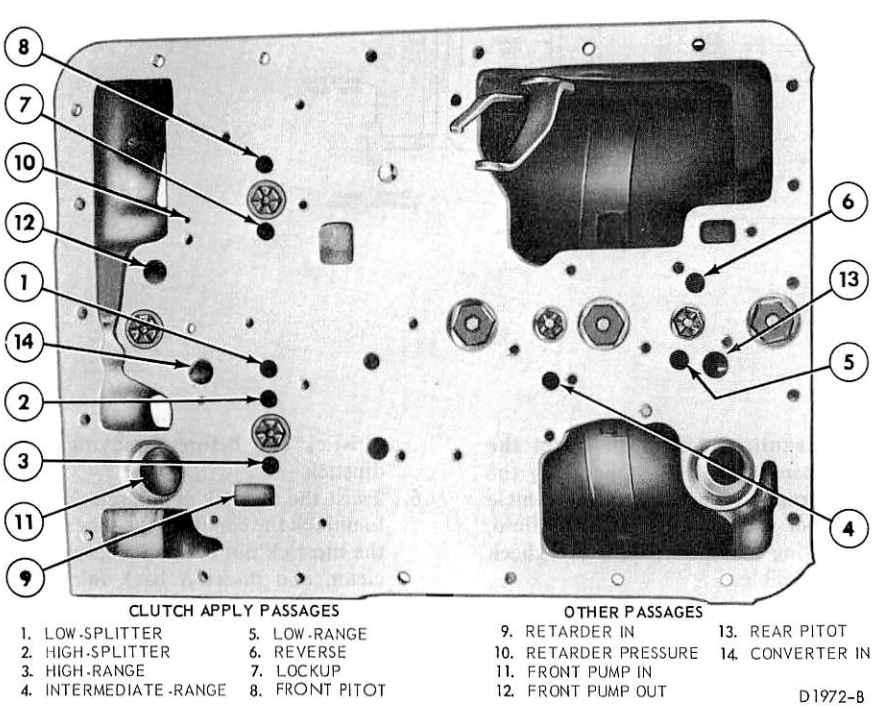

FIG. 4 Transmission Housing Fluid Passage Holes

mark, drain fluid until the FULL level is obtained.

8. Replace the dipstick in the tube. Turn the cap clockwise to lock it. **Failure to lock the cap may cause fluid leakage during retarder operation.**

If the fluid level remains low and leaks cannot be readily found, the use of dye tracers is often helpful in locating leaks. Oil-soluble aniline or fluorescent dyes, pre-mixed at 1/2 teaspoon of dye powder to 1/2 pint of transmission fluid, can help to determine whether an engine oil leak or a transmission fluid leak is present. Oil cooler leaks into the engine cooling system can also be found by using dye tracers. Always use a black light with the fluorescent dye solution.

After the leak has been found and corrected, the dye may be left in the transmission.

CONTROL PRESSURE CHECKS

Four 1/8-inch pipe plugs (Fig. 3) are provided in the transmission to check main, lockup, G1, and G2 fluid pressures.

All four pressures can be checked without driving the truck on the road. To obtain accurate readings, the procedures given below must be followed exactly.

All gauge readings should be taken with the transmission fluid at normal operating temperature (160-180 degrees F) and with the throttle and range selector linkage properly adjusted. The test point for main pressure (Fig. 3) is in the passage between the front pump outlet and the main pressure regulator valve. Since there is no check valve between the front pump and the main regulator valve, a gauge installed at this point will read main pressure under all operating conditions whether the pressure is coming from the front pump.

In normal operation, main pressure varies from 65 to 300 psi. Pressures vary with transmission model, converter and converter lockup operations, throttle positions, and range selector valve positions. Refer to the Specification Section for the fluid pressure checks.

SHIFT POINT CHECK

The Specification Section outlines the engine speeds at which the various shifts should occur.

AIR PRESSURE CHECKS

Moisture-free compressed air may be used to check the operation of the various clutches in the transmission, and to find leaks that may be caused by broken, damaged, or missing seals.

To make the air pressure checks, remove the oil pan, valve body, and oil transfer plate from the transmission. Then apply 85-100 psi (do not exceed 150 psi) air pressure at the appropriate holes in the mounting pad at the bottom of the transmission housing. These holes are identified and shown in Figure 4.

TRANSMISSION COOLING SYSTEM CHECK

Check the engine coolant level and add coolant if necessary.

If the fluid in the Transmatic Drive becomes contaminated with engine coolant (plain water, anti-freeze, or other additives), the transmission must be completely disassembled and thoroughly cleaned. Flushing will not remove the contaminated coolant from behind the pistons, fluid passages or converter.

Anti-freeze in the coolant may cause the transmission parts to be coated with gum. When this condition is encountered use either Butyl-Cellosolv or Methyl-Cellosolv (paint and varnish remover can be used as a substitute) to clean the metal parts. **Be sure that all passages in the case, diaphragm, piston housing, shafts, and valve bodies are clean and open before assembling the transmission.**

When a clutch failure or other internal trouble has occured in the transmission, any metal particles or clutch plate material that may have been carried into the oil cooler should be removed from the system by flushing the cooler before the transmission is put back into service. Foreign matter in the oil cooler system could block off the front pivot feed hole, get into various gears and clutches, or block off the output bushing lubrication orifice in the splitter shaft.

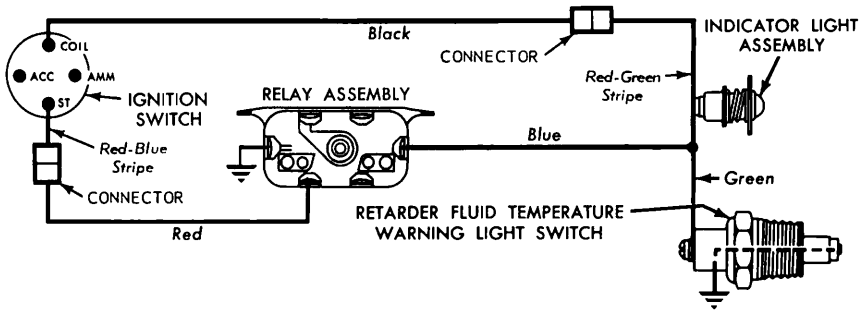

FIG. 5 Warning Light Circuit

TRANSMISSION FLUID TEMPERATURE WARNING LIGHT CHECK

Check the operation of the transmission fluid temperature warning light. The light should go on when the ignition key is turned to START, and it should go out when the ignition key is turned back to ON. The warning light circuit diagram is shown in Fig. 5.

RANGE SELECTOR LINKAGE CHECK

Move the range selector lever from 1-2 to R. Six definite detent positions (1-2, 3-4, 3-5, 3-6, N, and R) should be felt as the lever moves from front to rear.

HYDRAULIC RETARDER LINKAGE CHECK

The hydraulic retarder valve must travel a full 1/2 inch toward the rear, just before the retarder pedal hits the stop bolt. When the pedal is released, the retarder valve must travel 1/2 inch to the forward stop.

THROTTLE LINKAGE CHECK

When the throttle linkage is properly adjusted, maximum engine performance in starting and accelerating a heavily loaded truck is obtained automatically. The driver need only depress the accelerator pedal to the detent and hold it there. With the accelerator pedal held at the detent, the transmission will stay in the starting gear until engine crankshaft speed approaches the engine governed speed (maximum engine performance), then it will shift into the next higher gear. The automatic, full throttle (at detent) shifting just under governed speed will continue until the highest gear or desired road speed is reached.

ADJUSTMENTS

NEUTRAL START SWITCH

Check the starter circuit at all selector lever positions. The circuit must be open at all positions except N (neutral). To adjust, loosen the neutral switch to bracket attaching screws. Position the switch so that the starter circuit is closed when the selector lever is at N.

RANGE SELECTOR LINKAGE

1. Place the range selector lever at R.
2. Check the distance that the control cable adjusting threads extend above the sleeve assembled to the range selector arm (Fig. 6 or 7). This distance should not exceed 1/4 inch.
3. At the transmission, disconnect the range selector cable from the transmission control lever.
4. Shift the transmission control lever to R (all the way forward and upward).
5. Push the control cable up until the selector lever is at R. Adjust the threaded sleeve so that the sleeve pin just fits the hole in the control lever.
6. Assemble the sleeve on the lever.
7. From the driver's seat, feel for full

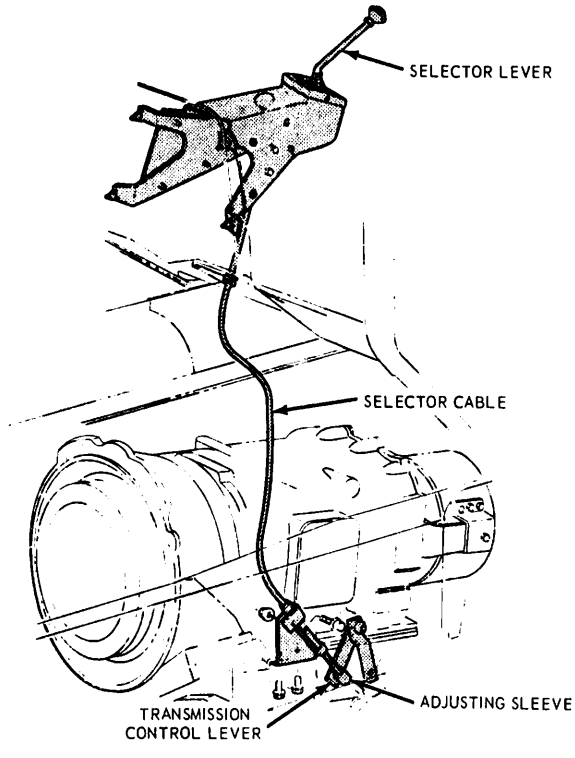

FIG. 6 Range Selector Linkage on L, LT, LN or LNT-Series Trucks

engagement at each detent position before the lever hits its stops.

HYDRAULIC RETARDER LINKAGE

L, LT, LTS, LN OR LNT-SERIES TRUCK

1. Check the hydraulic retarder pedal stop bolt height against the dimension shown in Fig. 8. Adjust as required.
2. Disconnect the hydraulic retarder control rod at the transmission end.
3. Pull the retarder lever toward the rear of the transmission until the retarder valve is heard and felt to bottom in the retarder casting.
4. Pull the control rod down until the pedal contacts its stop bolt.
5. With the retarder valve bottomed in its casting and the pedal against its stop bolt, adjust the control rod threaded sleeve.
6. Attach the control rod to the lever. Tighten the locknut.
7. Readjust the retarder pedal stop bolt height to provide 1/2 inch of travel at the retarder valve.
8. Check the adjustment by depressing the pedal against the stop bolt. Just before the pedal hits the stop bolt, the retarder valve should be felt to

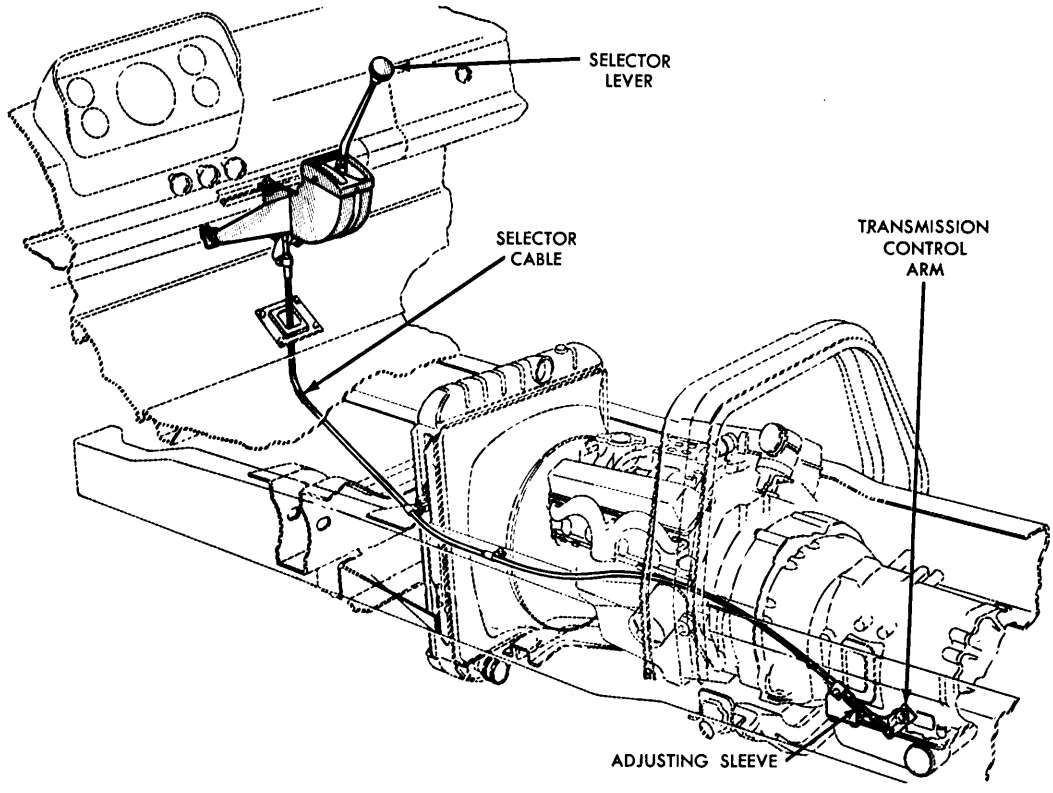

FIG. 7 Range Selector Linkage on C-Series Truck

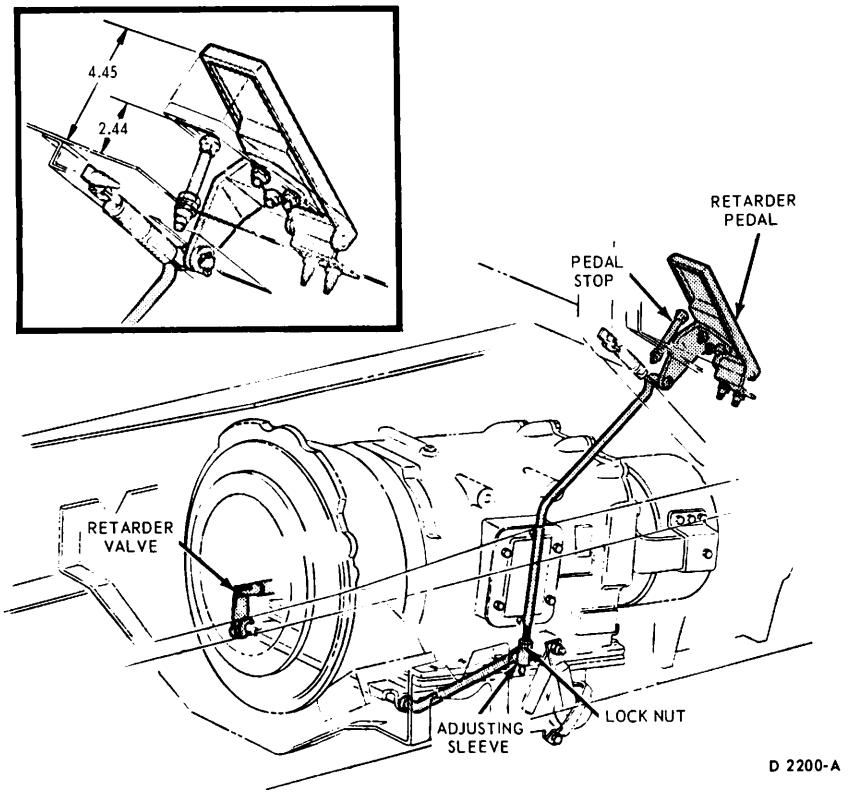

FIG. 8 Hydraulic Retarder L, LT, LN or LNT-Series Truck

bottom in its body. Check for full release. Readjust if necessary.

C-SERIES TRUCK

1. Adjust the retarder pedal stop bolt height as shown in Fig. 9.
2. Disconnect the retarder control cable at the transmission.
3. Pull the retarder lever toward the rear of the transmission until the retarder valve is heard and felt to bottom in its body.
4. Pull the retarder cable toward the transmission until the pedal is against its stop bolt.
5. With the retarder valve bottomed (all the way to the rear) and the retarder pedal against its stop, adjust the cable adjusting sleeve.
6. Attach the cable to the lever.
7. Readjust the retarder pedal stop bolt height to provide 1/2 inch of travel at the retarder valve.
8. Check the adjustment by depressing the pedal against the stop bolt. The retarder valve should be felt to bottom just before the pedal hits the stop bolt.

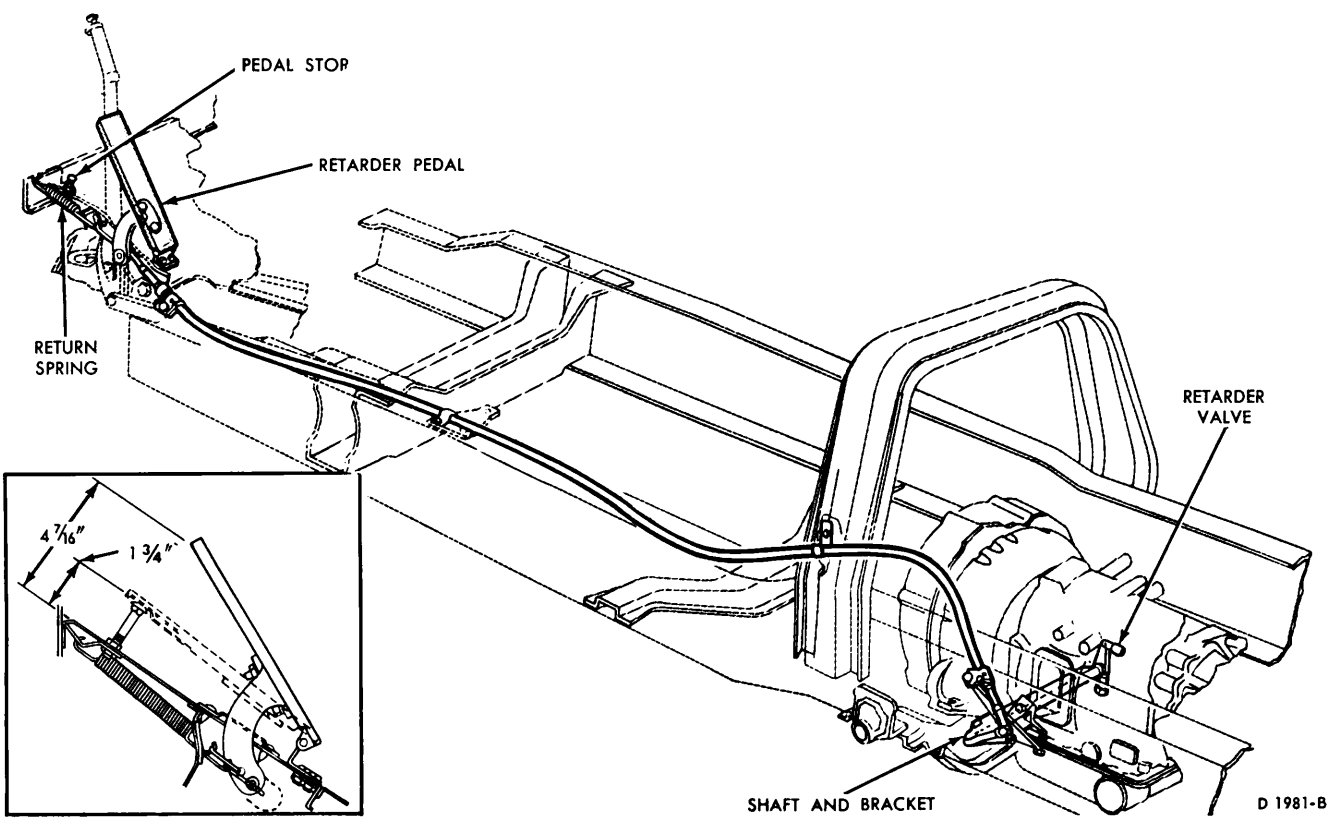

FIG. 9 Hydraulic Retarder Linkage on C-Series Truck

THROTTLE LINKAGE

The throttle linkage should be adjusted whenever the engine idle speed is changed, and whenever the transmission operation indicates that adjustment is required. Refer to Groups 24 or 25 for the detailed throttle linkage adjustment procedures.

CLOSED THROTTLE STOP

The closed throttle stop is accurately adjusted to each individual transmission in production. New service control valve bodies are **not preset. Therefore, whenever a new service control valve body is being installed, the closed throttle stop must be adjusted as follows:**

1. On the **removed** valve body, bottom the throttle valve.
2. Accurately measure the distance from the end of the valve to the end of the adjusting screw (Fig. 10).
3. On the new valve body, bottom the throttle valve and adjust the screw to get the dimension measured in step 2.
4. Crimp the sleeve against the adjusting screw to hold the adjustment.

FLYWHEEL HOUSING ALIGNMENT

Whenever the flywheel housing has been replaced, or when the original housing is to be used on another engine, check the alignment of the housing bore and rear face with the engine crankshaft.

1. Check the mating surfaces of the engine and the flywheel housing for raised metal, paint, nicks, or burrs. Remove any marks or material that would affect alignment.
2. Position the flywheel housing on the two dowel pins in the engine, then bolt the housing in place.
3. Check the runout of the flywheel housing bore and rear face with a dial indicator mounted on the engine crankshaft. If the total indicator reading of the bore runout exceeds 0.008 inch, or if the total indicator reading of the rear face runout exceeds 0.010 inch, repeat the check with another housing.
4. If either runout on the housing checked is not within limits, remove the two dowel pins from the engine. **Be careful not to drill the upper dowel pin too deeply as the dowel pin is in a blind hole which may break through into the water jacket or cylinder wall.**
5. Bolt the flywheel housing in place without dowel pins, then adjust the housing to get the correct bore runout. Tighten the bolts and ream the dowel pin holes large enough for oversize dowel pins.
6. Check the runout with the new oversize dowel pins in place, and with the mounting bolts tightened to 40-45 ft-lbs.

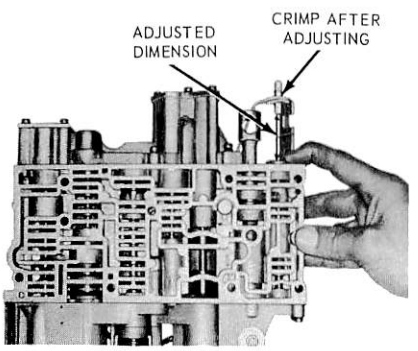

FIG. 10 Throttle Valve Adjustment

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

The torque converter and transmission must be removed from and installed in the vehicle as a unit. The transmission cannot be removed from or installed on the converter in the vehicle.

Except where noted, these removal and installation procedures apply generally to all vehicles.

1. If necessary raise the vehicle on a hoist. Loosen the filter cover and drain the transmission. The torque converter cannot be completely drained until it has been removed from the vehicle. **Do not remove the filter cover from the oil pan as the transmission fluid may gush out too quickly.** When the fluid stops flowing tighten the filter cover nut.
2. On a one-piece drive line, disconnect the shaft from the pinion flange and from the yoke at the parking brake drum. **Do not remove the bolt that attaches the flange on the transmission output shaft.** On a two-piece drive line, disconnect the coupling shaft from the yoke at the parking brake drum, and then remove the center support bearing bracket. Move the forward end of the drive shaft out of the way.
3. Disconnect the speedometer cable from the rear of the transmission.
4. Loosen the breather hose clamp on the fittings above the left power take-off plate, and then remove the fluid filler tube support strap bolt located halfway up the tube. Disconnect the tube at the oil pan, and remove the breather hose and tube together.
5. Disconnect the throttle control rod and the range selector lever cable from the levers on the left side of the transmission housing. Remove the cable clamp bracket from the housing.
6. Disconnect the hydraulic retarder linkage from the linkage cross shaft, and remove the cross-shaft from the front of the oil pan.
7. Disconnect the parking brake linkage.
8. Disconnect the fluid temperature warning light wire from the switch terminal on the retarder valve outlet fitting. Then remove the switch from the fitting.
9. Disconnect the oil cooler lines from the fittings on the retarder valve body, then remove the forward fitting. Plug the lines and valve body openings. If desired, the lines and valve body can be drained, but they should be plugged before removing the converter and transmission from the vehicle.
10. Remove the dust shield from the bottom front side of the flywheel housing.
11. Remove the six nuts and flat washers that hold the converter pump cover on the engine flywheel. The nuts and washers can be reached through an opening in the lower right side of the flywheel housing. The flywheel must be

turned to remove all nuts and washers. **The ignition system should be disconnected during this operation to prevent accidental starting of the engine.**

12. Cut the lock wires and remove the two bolts and nuts that hold the converter housing to the frame crossmember.
13. Cut the lock wire and remove the two bolts, washers, insulators from the top of the transmission rear support and crossmember.
14. Place an engine support under the rear end of the engine, then raise the engine to take the weight off the crossmember.
15. Support the transmission with a 1000-pound transmission jack. The jack should be placed so that the oil pan does not support the entire weight of the transmission. Fasten a safety chain over the top of the transmission and to both sides of the jack.
16. Remove the two bolts from each end of the transmission rear support crossmember, and remove the crossmember.
17. Remove the bolts and lock washers that attach the converter housing to the flywheel housing.
18. Move the converter and transmission away from the engine until the converter housing clears the crossmember, then lower the unit. If necessary, raise the floor pan slightly to permit the converter housing to clear the crossmember.

Installation

If the engine, flywheel, or flywheel housing has been replaced, check the flywheel housing alignment and flywheel shim adjustment before installing the torque converter and transmission.

1. Raise the converter and transmission on the jack, then move the unit into position over the crossmember that supports the converter. Align the studs in the converter cover with the holes in the flywheel. Install two guide studs in the flywheel housing, then push the unit forward so that the converter studs enter the holes in the flywheel.
2. Install the bolts, except the fluid filler tube support strap bolt, and lock washers that attach the converter housing to the flywheel housing. Torque them 23-28 ft-lbs.
3. Install six new self locking nuts and flat washers that hold the converter on the engine flywheel, and torque them to 34-40 ft-lbs.
4. Install the dust shield on the bottom front side of the flywheel housing.
5. Install the transmission rear support crossmember on top of the frame brackets, then install the two bolts on each end of the crossmember. Torque the bolts to 40-45 ft-lbs.
6. Lower the jack, remove it from under the vehicle, then remove the engine support from under the rear end of the engine.
7. Install the two bolts and nuts that hold the converter housing to the frame crossmember, and torque them to 70-91 ft-lbs. Install the lock wires.
8. Install the two bolts, washers, and insulators at the transmission rear support. Torque the bolts to 40-60 ft-lbs and install the lock wire.
9. Install the oil cooler line fitting in the forward fluid opening of the retarder valve body. **Then install the fluid temperature warning light switch on the fitting. Connect the warning light wire to the switch terminal.**
10. Connect the two oil cooler lines to the retarder valve body fittings.
11. Install the retarder linkage cross-shaft on the front of the oil pan, and torque the screws to 15-18 ft-lbs. Connect the retarder linkage to the cross-shaft and the valve.
12. Install the range selector lever cable bracket on the left side of the transmission housing, and torque the screws to 8-10 ft-lbs.
13. Connect the range selector lever cable and the TV rod to the levers on the left-hand side of the housing. **Be sure to install the TV rod in the outer hole of the lever.**
14. Connect the fluid filler tube to the oil pan, then install the tube support strap bolt in the converter housing.
15. Push the breather hose across the top of the transmission and connect it to the fitting above the left power take-off plate. Tighten the hose clamp.
16. Connect the parking brake linkage.
17. If the exhaust system was removed or disconnected during removal, install and connect the parts.
18. Install the drive shaft, the center bearing support bracket, and the coupling shaft. Connect the coupling shaft to the parking brake drum. Torque all nuts and bolts to specifications.
19. Connect the speedometer cable to the rear of the transmission.
20. Adjust the retarder, throttle control rod, and range selector lever linkages.
21. Check all fluid line connections and the filter cover for tightness, then lower the vehicle to the floor.
22. Add enough automatic transmission fluid to the converter and transmission to bring the fluid level to the full mark on the dipstick.

CONTROL VALVE BODY

Removal

1. Remove the fluid filter cover and gasket, then remove the retainer and filter from the transmission oil pan.
2. Remove the oil pan and gasket.
3. Remove the filter can and pickup tube assembly from the top of the control valve body.
4. Remove the seal rings from the front pump pickup tube.
5. Remove the eight bolts that hold the control valve body on the oil transfer plate, and lift the body from the plate (Fig. 11). The shift valve steel detent ball and spring and the nylon ball are free to fall out of the valve body when it is removed from the transfer plate.

Installation

If a new control valve body is being installed, the closed throttle stop must be adjusted as described in Steps 1 thru 4 below.

1. On the **removed** valve body, bottom the throttle valve.
2. Accurately measure the distance from the end of the valve to the end of the adjusting screw (Fig. 10).
3. On the **new** valve body, bottom the throttle valve and adjust the screw to get the dimension measured in step 2.
4. Crimp the sleeve against the adjusting screw to hold the adjustment.
5. Place the detent shift valve spring in the oil transfer plate and the steel ball in the control valve body. Hold the ball in place with the oil-soluble grease. Position the control valve body on the plate, making sure that the range selector shaft enters the hole in the control valve and that the TV lever is against the valve. Install the attaching bolts, sleeves and lock washers and torque evenly to 4-6 ft-lbs.
6. Place a new seal ring on the long tube end of the filter can and install the assembly over the control valve body.
7. Install a new oil pan gasket on the transmission housing with the bolt holes properly aligned.
8. Inspect the oil pan for damage. If the pan is severely damaged, replace it.
9. Install the oil pan on the housing. Install the oil pan bolts and lock washers and torque to 15-18 ft-lbs.
10. Install a new fluid filter element in

the oil pan and install the fluid filter retainer, a new gasket, and the cover.

OIL TRANSFER PLATE

Removal

1. Remove the control valve body as outlined in this Section of the Manual.
2. Remove the downshift timing valve body from the transfer plate.
3. Remove the transfer plate from the transmission housing. A nylon ball in the plate is free to fall when the plate is removed.
4. Remove the hydraulic retarder valve body and gasket. Remove the nylon ball from the housing.

Installation

1. Insert the hydraulic retarder valve teflon ball in the transmission housing, install a new gasket on the transmission housing, and then install the hydraulic retarder control valve body assembly (Fig. 12). Install the mounting bolts. Torque the long bolts to 14-17 ft-lbs and the short bolts to 15-18 ft-lbs.
2. Position the oil transfer plate on the housing (Fig. 13).
3. Coat the lube line check valve nylon ball with oil-soluble grease and insert it into the oil transfer plate. Install the oil transfer plate. Install the oil transfer plate and secure it with the 10 bolts and lock washers (Fig. 14). Install the two short bolts at the thin section of the oil transfer plate. Torque the bolts to 8-10 ft-lbs.
4. Position the downshift timing valve body on the oil transfer plate and install the three short bolts and lock washers. Torque the bolts to 8-10 ft-lbs.
5. Reinstall the control valve body.

TRANSMISSION FLUID CHANGE AND FLUID FILTER

Removal and Installation

On a new vehicle the transmission fluid should be drained and a new filter installed after the first 2000 miles of operation. Thereafter, in normal highway operation, the fluid and filter should be changed as recommended in the maintenance manual. If the vehicle is in off-the-highway or frequent stop-and-go service the fluid and filter should be changed at more frequent intervals.

After the correction of any transmission failure, change the fluid and install a new filter. After a major failure, replace the fluid and filter at overhaul and again after 500 miles (or 15 hours) of operation.

1. If the fluid is cold, operate the transmission until a normal operating temperature is reached.
2. Loosen, but do not remove, the screw which secures the filter cover to the transmission pan (Fig. 15).
3. Carefully separate the filter cover from the pan at the bottom edge only. When the drainage is complete, remove the cover, retainer, and filter. Discard the filter and fluid.
4. Install a new filter. Install a new retainer seal ring, filter retainer, a new cover seal ring, cover and strap. Tighten the strap attaching screw (Fig. 15).
5. Slowly pour 9 quarts of automatic transmission fluid into the transmission. Apply the parking brake securely then start the engine.
6. With the hand throttle, set engine speed at idle speed rpm with the selector lever at N.
7. Check the transmission fluid level when the engine reaches normal operating temperature. If necessary, add fluid to bring the level to the ADD FLUID mark.
8. Continue to run the engine until the transmission fluid reaches normal operating temperature.
9. Apply the service brakes, and shift the transmission through all ranges.
10. With the engine running and the selector lever at N, check the fluid level. Add fluid, if necessary, to bring the level to the FULL mark. Approximately 13 quarts are required if the oil pan and control valve body have been removed. Total dry capacity for the transmission and cooling system is approximately 19 quarts.

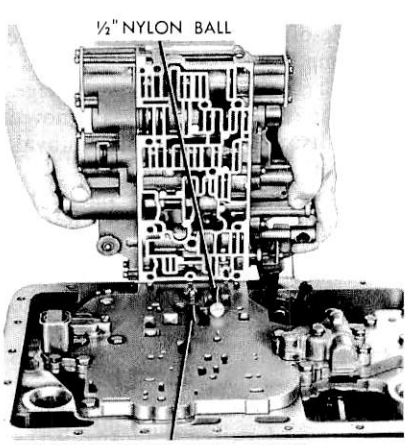

FIG. 11 Valve Body Removal and Installation

BUSHING OR BEARING

Removal and Installation

Replacement bushings are available for the converter pump cover, input shaft, converter stator support, high-splitter clutch housing, and output shaft. These bushings are pre-finished (no reaming required). Therefore the old bushing must be removed without damaging the bore, and the new bushing must be installed without damaging it.

Tools for removing and replacing the bushings are shown in Fig. 16. The bushing replacer tools should be used in a press. They are so designed that the

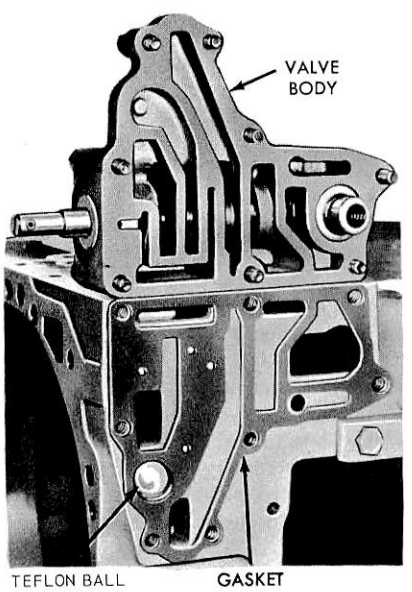

FIG. 12 Valve Retarder Removal and Installation

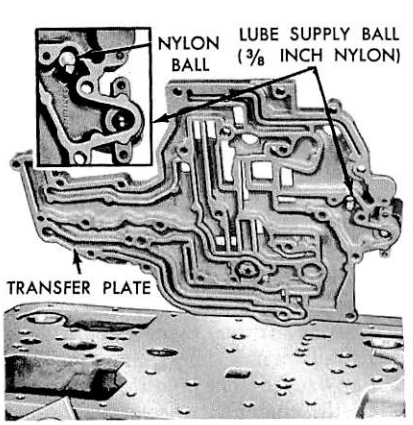

FIG. 13 Transfer Plate Installation

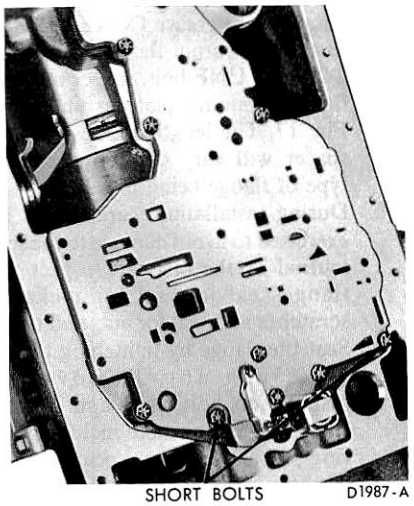

FIG. 14 Transfer Plate Bolts

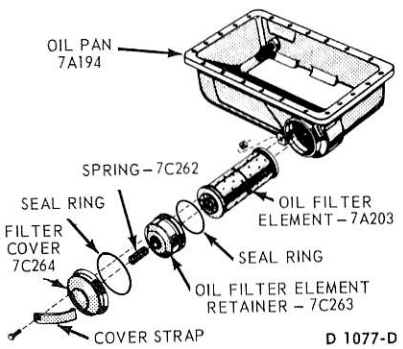

FIG. 15 Fluid Filter Assembly

bushings are properly located when the tool bottoms.

Wear limits for the various bushings are given in the specifications section.

SPEEDOMETER DRIVE GEAR

Removal and Installation

1. On a one-piece drive line, disconnect the shaft from the pinion flange and from the yoke at the parking brake drum. On a two-piece drive line, disconnect the coupling shaft from the yoke at the parking brake drum and then remove the center support bearing bracket. Move the forward end of the drive shaft out of the way.
2. Disconnect the speedometer cable from the rear of the transmission.
3. Loosen the two rear pitot tube mounting bolts until they protrude 1/16-inch. **To prevent damage to the pitot tube or governor oil collector ring, these bolts must be loosened before loosening the output flange attaching bolt.**
4. Straighten the output shaft flange tab lockwasher and remove the bolt, washer, and O-ring seal.
5. Remove the parking brake drum and output flange; use a suitable puller if necessary. **Do not turn the output shaft until the output shaft flange attaching bolt is reinstalled. Otherwise, damage to the pitot tube or governor vanes may result.**
6. **Using Tool 1175-AE with T50T-100-A, remove the output flange seal.**
7. Remove the internal snap ring.
8. Using Tool 1175-AE with T50T-100-A, remove the rear bearing.
9. Using needle nose pliers or a piece of wire, remove the speedometer drive gear. Install the speedometer drive gear. The counterbored end faces out.
10. Start the rear bearing straight into the bore of the retainer and, using Tool T57L-600-A, drive the bearing tight against the shoulder in the retainer.
11. Install the internal snap ring.
12. Coat the outside diameter of a new output flange seal with a very thin film of Permatex, and start the seal straight into the retainer with the lip of the seal toward the bearing. Using Tool T57L-600-A, press the seal into the bore until the rear of the seal is 3/4 inch beyond the extreme rear surface of the bearing retainer housing.
13. Install the output shaft flange and parking brake drum.
14. Install the O-ring seal, tab lock washer, and output shaft bolt. Torque the bolt to 10 ft-lbs. **Do not allow the shaft to rotate while tightening the bolt.**
15. Torque the rear pitot tube bolts to 8-10 ft-lbs.
16. Torque the output shaft flange bolt to 83-100 ft-lbs, and lock it by staking the tab lockwasher into the hole in the retainer and bending a tab against a flat of the bolt head.
17. Connect the speedometer cable to the rear of the transmission.
18. Connect the drive shaft or the coupling shaft and center support bearing bracket. Torque the nuts and/or bolts to specification.

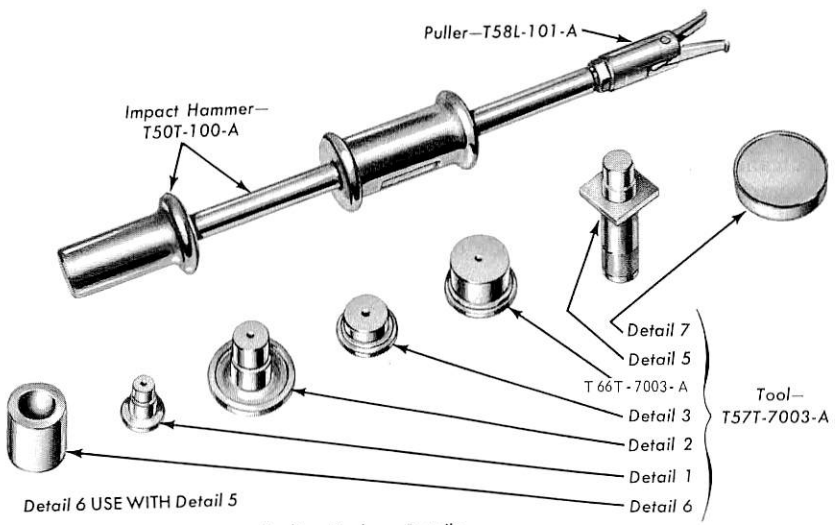

FIG. 16 Bushing Replacing Tools

UNIVERSAL JOINT FLANGE AND PARKING BRAKE DRUM

Removal and Installation

Before removing the parking brake drum, it is necessary to remove the universal joint flange.

1. The transmission may be placed in either a vertical or horizontal position on the input drive cover or sump pan. Remove flange attaching bolt, with washer and O-ring seal. Do not remove washer and O-ring from the bolt. Remove the flange.
2. Do not allow the output shaft to turn until the flange is installed, seated and the attaching bolt has been torqued. If the output shaft is allowed to rotate, damage to the pitot tube and/or governor will result.
3. Remove the parking brake drum

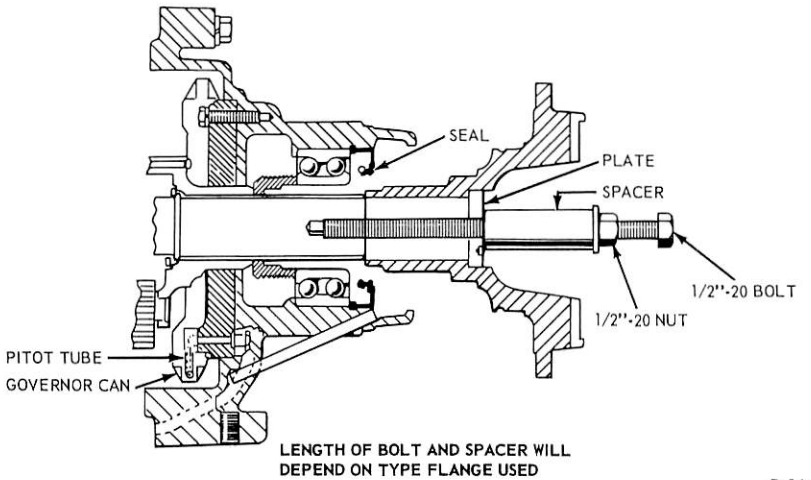

FIG. 17 Installing Output Shaft Flange

attaching bolts and remove the drum.
4. Position the drum and install the attaching bolts.
5. Torque the bolts to specification being careful not to rotate the output shaft.
6. Lubricate the output seal with a high temperature grease COAZ-19584.
7. Install the output flange, using a 1/2-20 inch UNF bolt, spacer nut and flange retaining plate as shown in Fig. 17. The length of the bolt and spacer will vary depending on the type of flange being installed.
8. During installation, care should be exercised to avoid damage to the seal journal or the oil seal. Inspect the flange seal journal for nicks or scratches and seal for cuts and tears.
9. Seat the flange by tightening the 1/2-20 inch nut. Remove the installation bolt, nut, and spacer. Install attaching bolt including O-ring seal and washer. Locate the tab of the washer opposite the hole in the flange retaining plate.
10. Prevent the output flange from rotating then torque the bolt to 83-100 ft-lbs. Bend the tab of the washer against a flat of the bolt head and stake the edge of the washer into the hole of the retaining plate.
11. Rotate flange by hand to check for binding or interference.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

1. Proper equipment must be available before disassembly is started. This equipment includes a suitable hoist of at least 1/2-ton capacity, proper hand tools and special tools, and a press.
2. Gaskets, lock wires, lock strips, and cotter pins should be discarded as they are removed. New parts of this type should always be installed.
3. Care must be used to avoid damage to transmission components during disassembly, cleaning, inspection, repair, and assembly operations. Nicks, and scratches caused by careless handling may cause fluid leakage or improper functioning and could result in transmission failure. All worn or damaged parts must be repaired or replaced. Where special torque requirements apply, refer to the specifications section.
4. Cleanliness is important in servicing the transmission. All components must be thoroughly cleaned and kept clean throughout the rebuild process. The presence of dirt can cause malfunction, and possible failure of the transmission.
5. Every component should be thoroughly cleaned after the transmission is disassembled. Cleaning is necessary to insure effective inspection for wear, damage, and serviceability of components.
6. Crocus cloth may be used to remove minor surface irregularities.
7. A soft wire (brass or copper) may be used to clean fluid passages. Always flush such passages thoroughly after cleaning.
8. If steam cleaning is used, dry the cleaned parts immediately with compressed air and apply a film of oil to prevent rusting. Never use lye or caustics which will corrode or etch metal surfaces.
9. Do not clean the lubricant from new bearings. Keep new bearings wrapped until they are to be installed. Soak bearings which have been in service, in dry cleaning solvent or mineral spirits paint thinner to loosen deposits of dirt. Do not spin the bearings during cleaning or drying. After cleaning, turn the bearings by hand and note any evidence of grit. Clean them if grit is present.

Disassembly

1. With the transmission assembly removed from the vehicle remove the fluid filter, oil pan, valve body, oil, transfer plate, and hydraulic retarder valve and gasket.
2. Remove the converter pump cover, lockup clutch reaction plate, and clutch plate (Fig. 18). Remove the seal ring from the reaction plate and pump.
3. Remove the hook-type seal ring and the snap ring from the turbine shaft, and remove the turbine from the shaft (Fig. 19).
4. Rotate the stator counterclockwise to lock it on the freewheel roller race. Then lift the stator and roller race off the converter pump

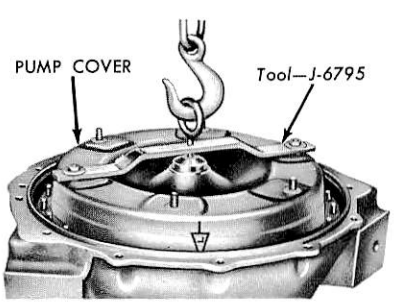

FIG. 18 Converter Pump Cover Removal

together. **Do not let the freewheel roller race drop out of the stator.**

5. Remove the snap ring and spacer from the converter stator support, and lift out the converter pump assembly.
6. Remove the converter housing mounting bolts and lift off the housing and gasket. **Lift the housing carefully to avoid dropping the retarder rotor and shaft assembly. If this assembly lifts with the housing, tap the end of the shaft to dislodge it from the housing so it will remain in the transmission.**
7. Remove the thrust bearing from the rear face of the converter stator support assembly. The bearing race may remain on the retarder rotor and shaft assembly.
8. Lift out the retarder rotor and shaft (Fig. 20). Remove the hook-type seal ring and thrust washer.
9. Remove the low-splitter clutch reaction plate anchor bolt. Loosen the bolt at the top of the transmission housing which anchors the diaphragm assembly in the housing.
10. Remove the low-splitter clutch reaction plate.
11. Remove the anchor bolts that hold the low-splitter piston housing and diaphragm assembly. Then install the lifting hook in the end of the splitter outshaft and remove the assembly (Fig. 21).
12. Position the transmission with the rear bearing retainer up.
13. Remove the two pitot tube bolts and the speedometer plug.
14. Remove the brake drum. Hold the output flange to prevent rotation and remove the flange retaining bolt, tab lock washer and the O-ring seal.
15. Use a suitable puller and remove the output shaft flange.
16. Remove four bolts and lift the brake assembly and apply lever from the transmission.
17. Remove the reverse, low, and intermediate range clutch reaction housing anchor bolt nuts. Remove the low-range piston housing anchor bolt and the intermediate-range piston housing anchor bolt. Remove the cap screws securing the rear bearing retainer to the transmission housing and remove the retainer and gasket. Lift out the loose pitot tube.
18. Remove the reverse planetary carrier and rear pitot collector ring from the output shaft. **Various factory installed clutch parts are color coded, and should be assembled in the same locations when the transmission is serviced to insure proper fitting. Parts marked yellow are for the intermediate range clutch, those marked green are for the low-range clutch, and those marked red are for the reverse clutch.** Replacement parts are not color coded.
19. Remove the thrust washer and snap ring from the output shaft and the snap ring from the reverse sun gear and the internal-splined thrust washer.
20. Remove the reverse clutch reaction housing, backing plate, clutch plate(s) and ring gear. Then take out the reverse clutch Belleville spring. Remove the reverse range reaction housing anchor bolt.
21. Working through the openings in the transmission housing, remove the low-range and reverse-range clutch piston housing.
22. Remove the low-range clutch Belleville spring.
23. Remove the low-range clutch apply plate and the low-range clutch plate(s).
24. Remove the low-range clutch

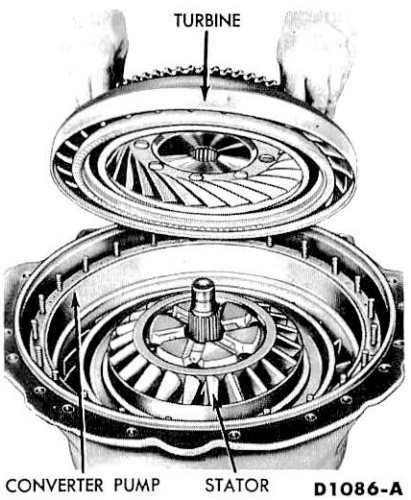

FIG. 19 Turbine Removal or Installations

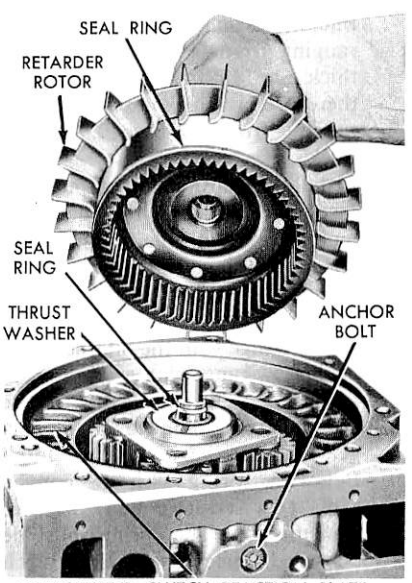

FIG. 20 Retarder Rotor Removal or Installation

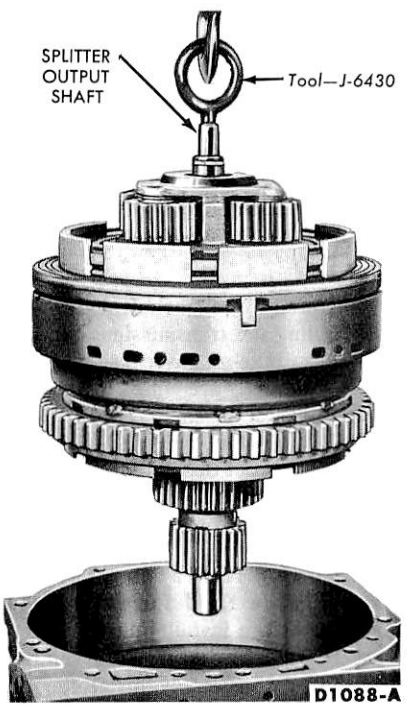

FIG. 21 Removing Splitter Mechanism

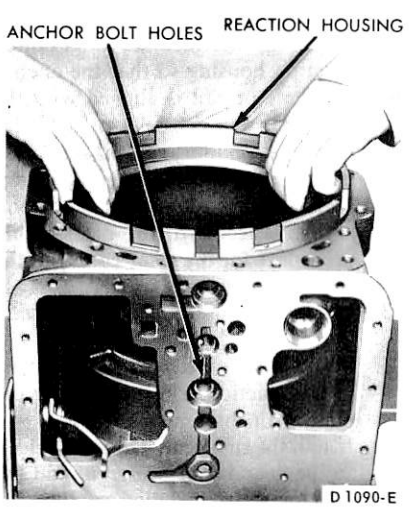

FIG. 22 Low-Range Clutch Reaction Housing Removal or Installation

reaction housing (Fig. 22).
25. Remove the low-range anchor bolt.
26. Remove the large internal snap ring that holds the reverse sun gear shaft to the low-range ring gear, then remove the reverse range sun gear shaft.
27. Remove the output shaft assembly.
28. Remove the low-range ring gear and intermediate-range planetary carrier (Fig. 23).
29. Remove the intermediate-range housing and piston assembly from the transmission housing.
30. Remove the intermediate-range clutch Belleville spring. Then remove the apply plate, the clutch plates, and ring gear.
31. Remove the intermediate clutch reaction housing from the transmission housing.
32. Remove the intermediate-range square head anchor bolt.
33. Remove the oil collector.

Assembly

Do not use gasket sealer when assembling the transmission, except on the power take-off cover (use sparingly). As mating parts are pulled together, the excess sealer is squeezed out of the splitline into the transmission. A very small amount of this material can affect the functioning of the various valves which control the operation of the transmission.

Soak all-clutch plates in transmission fluid for at least two minutes before installation.

1. If a housing shim was removed during disassembly, install the same shim. **If a new housing (case) is used, do not use the old shim.** Install the oil collector with the conical portion facing toward the front of the housing.
2. Install the intermediate-range clutch reaction housing so that the anchor bolt hole or slot is aligned with the hole in the bottom of the transmission housing. Install, but do not tighten the intermediate-range clutch reaction housing anchor bolt and nut. **Refer to the disassembly procedure for the color coding of the clutch components.**
3. Position an internal-splined plate in the reaction housing.
4. Position the externally splined plate in the reaction housing, mating the plate with the housing slots.
5. Install the ring gear. **The ring welded to the gear is not centered, and the gear must be installed so that the longer spline teeth engage the front clutch plate splines (Fig. 24).**
6. Position the other internally splined clutch plate, meshing the plate splines with the spline teeth of the ring gear.
7. Install the apply plate. The intermediate range apply plate is available in six thicknesses, ranging from 0.270 to 0.316 inch.
8. Install the intermediate-range clutch Belleville spring with the convex side toward the rear of the transmission. The spring must be entered perfectly on the clutch apply plate so that the intermediate-range piston housing will seat properly around it.
9. Install the intermediate-range piston housing with the piston facing the Belleville spring and with the tapped hole in the piston housing in line with the corresponding anchor bolt hole in the bottom of the transmission housing.
10. Install, but do not tighten, the intermediate-range clutch piston housing anchor bolt.
11. Install the low-range ring gear and intermediate-range planetary carrier (Fig. 23). Rotate the assembly until the planetary pinion teeth engage the internal teeth of the intermediate range ring gear.
12. Install the low-range clutch reaction housing, aligning the tapped hole or slot in the plate with its corresponding anchor bolt hole in the bottom of the transmission housing (Fig. 22). Install the reaction housing anchor bolt and nut. **Do not tighten.**
13. Install the clutch plate(s) and the clutch apply plate. The low-range apply plate is available in three thicknesses on MT30 and 31 models, ranging from 0.458 to 0.476 inch thick. On MT40, 41 and 42 models there are six thicknesses available, ranging from 0.270 to 0.316 inch thick.
14. Install the transmission output shaft assembly, engaging the planetary pinion teeth with the internal teeth of the low-range ring gear.
15. Install the reverse sun gear shaft over the output shaft. Mesh the teeth on the flange with the internal teeth of the low-range ring gear.
16. Install a new snap ring in the internal groove of the low-range ring gear, install the low-range clutch Belleville spring with the convex side toward the rear of the transmission. The spring must be centered perfectly on the clutch apply plate so that the low-range and reverse clutch piston housing will seat around it.
17. Install the low-range and reverse clutch piston housing assembly with the long (reverse) hub up, aligning the tapped hole (most models) in the piston housing with the corresponding anchor bolt hole in the bottom of the transmission housing. **Refer to the disassembly procedure for the correct color code.**

    Replacement parts are not color coded. Do not install the anchor bolt at this time.
18. Install the reverse clutch Belleville spring with the concave side toward the rear of the transmission. Depress the Belleville spring edge and install the square head anchor bolt from inside the transmission.
19. Before installing the reverse clutch pack in the housing, assemble it as follows:

    Place the clutch apply plate on a bench with the flat surface up. Position the reverse ring gear and clutch plate assembly on the apply plate with the longer section of the ring gear external teeth up. Over these parts, position the reverse reaction housing with the slots down so the slots engage the clutch apply plate tangs.

    Install this assembly in the transmission housing, aligning the tapped hole or slot in the reaction housing with the corresponding anchor bolt in the bottom of the transmission housing. **Do not install the anchor bolt at this time.**
20. Install the reverse sun gear splined thrust washer on the reverse sun gear shaft.

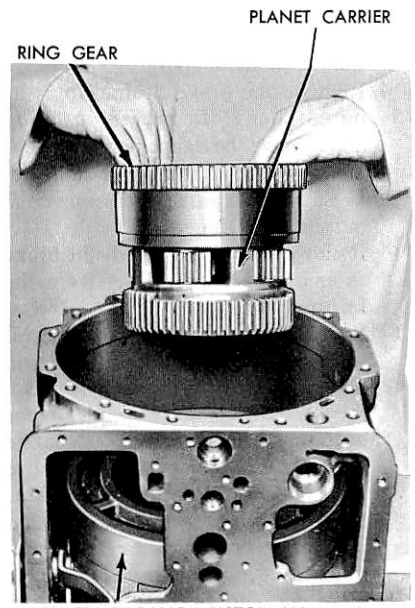

FIG. 23 Ring Gear and Planet Carrier Removal and Installation

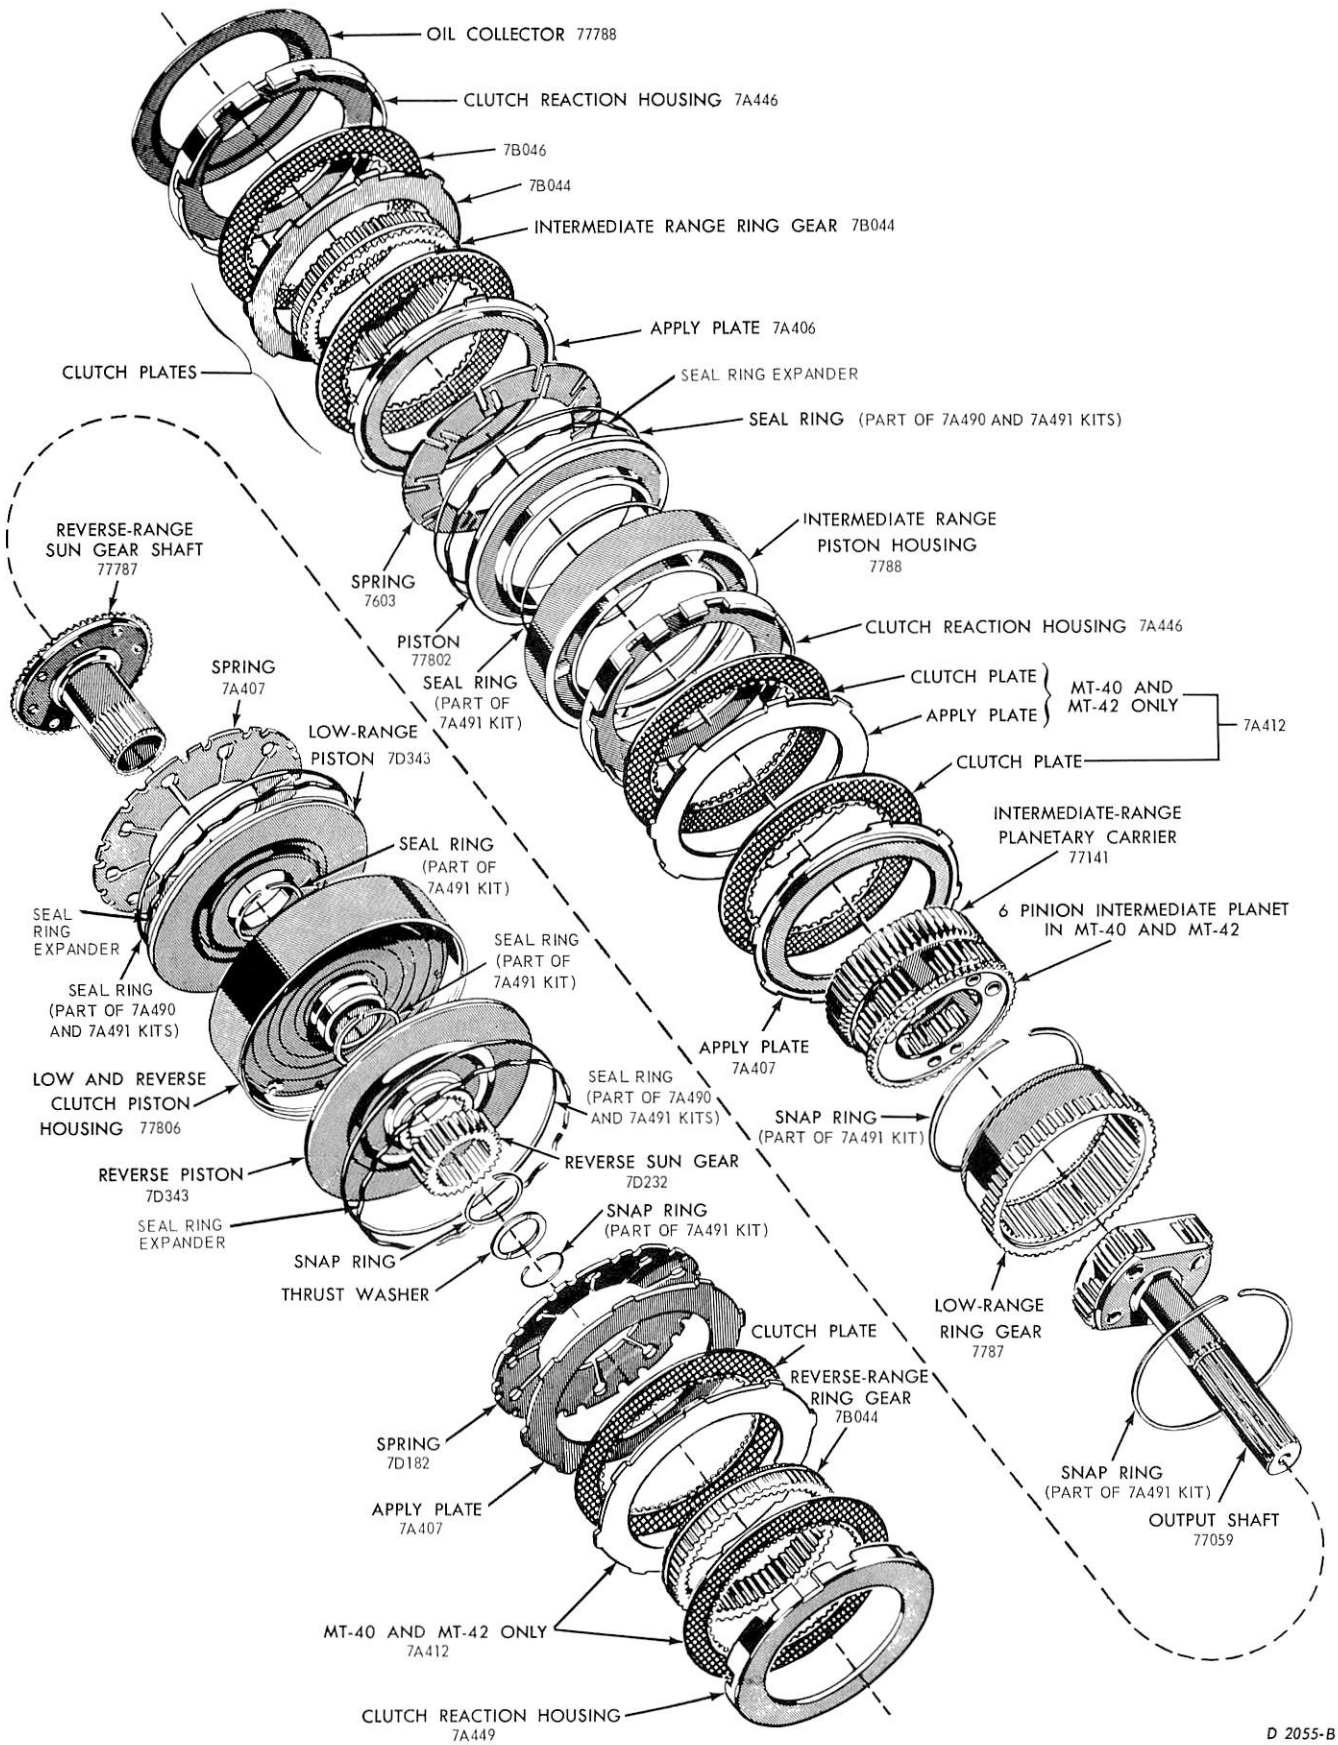

FIG. 24 Typical Range Clutches and Gears (Intermediate, Low and Reverse)

Install the reverse sun gear on the sun gear shaft, then install a new snap ring.

21. Install the bronze thrust washer over the output shaft. Install the reverse planetary carrier locating snap ring (wire) on the output shaft.
22. Install the reverse planetary carrier and the rear pitot collector ring on the output shaft. Make sure the planetary pinions mesh with the sun gear and internal teeth of the reverse ring gear.
23. With the rear pump (or adapter) and speedometer drive gear removed, install the rear bearing retainer, without a gasket, on the rear of the transmission housing.
24. Install four bearing retainer mounting bolts at 90 degree intervals, and torque the bolts to 85 in-lbs. This torque applies to gasket selection only. Draw the bearing retainer down evenly toward the transmission housing.
25. Check the clearance between the bearing retainer and the rear surface of the transmission housing near the points where the bolts are installed (Fig. 25). This clearance will determine which gasket or gaskets to use.

Gaskets are available in 0.012, 0.016, and 0.021 inch thickness. If the gaskets are not clearly marked, measure them with a micrometer. The gasket thickness for various clearances is given below:

Clearance of 0.005-0.015 inch, use the 0.012 gasket.

Clearance of 0.015-0.021 inch, use the 0.016 gasket.

Clearance of 0.022-0.027 inch, use the 0.021 gasket.

Clearance of 0.028-0.033 inch, use one 0.012 and one 0.016 gasket.

26. **Install, but do not tighten, the low-range and reverse clutch piston housing anchor bolt and the reverse clutch reaction housing anchor bolt.**
27. **Remove the four bearing retainer bolts and remove the bearing retainer.**
28. Torque the five anchor bolts installed in the bottom of the transmission housing to 10 ft-lbs. **This torque is temporary.**
29. Install the correct rear bearing retainer gasket. Install two guide bolts in the rear pitot tube. Make sure the open (drilled Port) side of the pitot tube is toward the bolts. To make a guide bolt, thread one end of a 6-inch long by 1/4-inch diameter brazing rod. Use a 1/4-inch-28 die and thread a distance of 3/8-inch. Round off the unthreaded end.

Guide bolts are recommended. If guide bolts are not available, install the pitot tube as follows exercising extreme care as the tube threads are soft aluminum:

Place the pitot tube on the mounting pad of the rear pump body. Using a pair of side-cutting pliers, crimp two or three threads near the end of a soft 1/4-28 bolt. Insert the crimped thread through the rear of the bearing retainer and screw it into the pitot tube until it binds enough to control the movement of the pitot tube. Swing the pitot tube toward the center of the bearing retainer so that it will clear the pitot collector ring when the retainer is installed, then install the retainer. Turn the pitot tube to its normal position and start a mounting bolt. Pull the pitot tube tight and remove the crimped installation bolt. Install the other pitot mounting bolt. Leave 1/16-inch or more of the mounting bolts protruding at the rear of the retainer.

30. Place the pitot tube in the rear pitot collector ring with the tube portion toward the vanes and the guide bolts toward the rear of the transmission (Fig. 26).
31. Carefully lower the rear bearing retainer over the output shaft while guiding the ends of the guide bolts through the pitot tube mounting bolt holes in the retainer. It also will be necessary to guide the rear pump drive lugs into the driving slots in the reverse planetary carrier and to start the speedometer drive gear on the output shaft. Do not remove the pitot tube guide bolts at this time. Do not turn the output shaft until the output flange (retaining) attaching bolt is installed. Otherwise, damage to the pitot tube or governor vanes may result.
32. Install the rear bearing retainer bolts and lock washers. At this time, tighten the piston housing anchor bolts 3-10 ft-lbs torque to seat the housings firmly. Then torque the retainer bolts to 42-50 ft-lbs.
33. Tighten the three low-and intermediate range and reverse clutch reaction housing anchor bolts to 35-40 ft-lbs. Tighten the nuts to 65-75 ft-lbs. Be sure to use new nuts only. The old nuts are not reusable.
34. Torque the two piston housing anchor bolts to 20-23 ft-lbs.
35. While pulling outward on one pitot tube guide bolt, replace the other guide bolt with a mounting bolt, replace the second guide bolt in the same way. Do not tighten the mounting bolts at this time. The mounting bolts should protrude 1/16-inch or more.
36. Install the brake support plate assembly on the bearing retainer and at the same time, install the brake apply lever and cam (Fig. 27). Tighten the bolts to 67-80 ft-lbs torque.

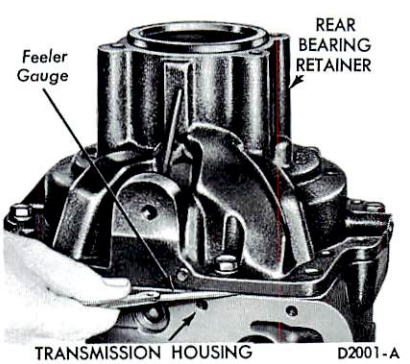

FIG. 25 Rear Bearing Retainer Gasket Measurement

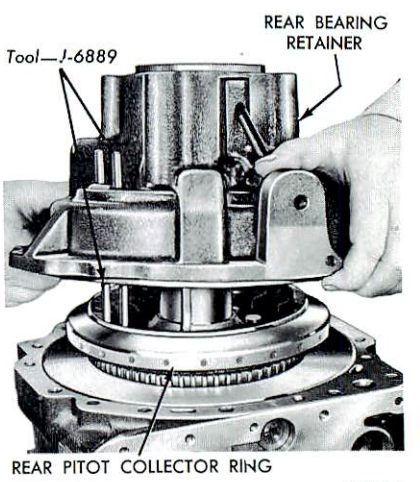

FIG. 26 Rear Bearing and Pitot Tube Installation

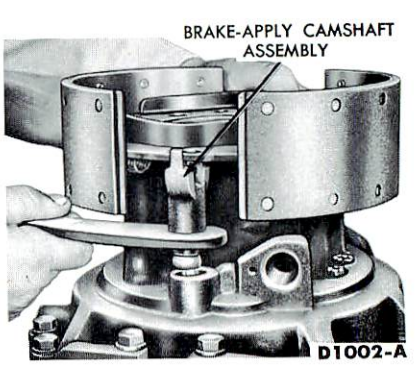

FIG. 27 Parking Brake Installation

37. Install the output shaft flange and parking brake drum. Do not turn the output shaft while installing the flange and drum. If the shaft is turned, damage to the pitot tube or governor may result.
38. Install the O-ring seal, tab lock washer, and output shaft bolt. Torque the bolt to 10 ft-lbs. Do not allow the shaft to rotate while tightening the bolt.
39. Torque the rear-pitot tube bolts to 8-10 ft-lbs.
40. Torque the output shaft flange bolt to 83-100 ft-lbs and lock it by staking the tab lock washer into the hole in the retainer and bending a tab against a flat of the bolt head.
41. Adjust the parking brake.
42. Position the transmission with the front surface facing upward.
43. Install the lifting hook in the front end of the splitter output shaft and install the splitter section and high range clutch assembly (Fig. 21). The three anchor bolt holes in the high-range clutch diaphragm assembly must align with the two holes in the bottom of the transmission and one hole in the top of the housing.
44. Start all three anchor bolts. On the top bolt (Fig. 28), leave approximately 1/8-inch gap between the bolt head and the transmission housing. Using a speed wrench, tighten bolt A. Loosen the bolt, then pull it up snug.
45. Tighten bolt B to 20-23 ft-lbs torque.
46. Tighten bolt A to 20-23 ft-lbs torque.
47. If the top bolt is finger loose, tighten it to 20-23 ft-lbs torque. If it is not finger loose, loosen bolts A and B and re-torque reversing the torque sequence. The top bolt should be torqued to 20-23 ft-lbs only if it is finger loose. Failure to tighten the bolts in the order described, may cause internal fluid leaks, resulting in low pressures and erratic shifts.
48. Install the low-splitter clutch reaction plate with the vanes toward the front of the housing and the anchor bolt hole in line with the hole in the bottom of the housing.
49. Install the reaction plate anchor bolt and torque it to 20-23 ft-lbs.
50. Install the hook-type seal ring around the splitter ring gear of the turbine shaft and hydraulic retarder rotor (Fig. 20).
51. Make sure that the thrust washer is in front of the splitter planetary carrier assembly and that the hook-type seal ring is in the groove at the front of the splitter output shaft assembly (Fig. 20). Oil the thrust washer and the hook-type seal ring then install the turbine shaft and hydraulic retarder rotor assembly. Be careful to avoid damaging the hook-type seal ring at the front of the splitter output shaft.
52. Position the converter housing gasket on the front of the transmission housing.
53. Install the needle roller bearing and needle bearing assembly. Be sure the rollers in the assembly are facing down. Then install the converter housing on the transmission housing assembly and secure it with the 10 mounting bolts and lock washers. Torque the bolts to 42-50 ft-lbs.
54. Install the hook-type seal ring on the converter pump hub.
55. Install the converter pump in the converter housing. Make sure the flats on the hub mate with the front pump drive flats and that the hook-type seal ring on the hub passes through the front pump seal without damage to the seal ring or seal.
56. Install the splined spacer and the snap ring which retains it.
57. Hold the freewheel roller race in the stator, and install the stator on the stator support as shown in Fig. 29. The stator should rotate freely in the direction of engine rotation (clockwise) and should lock up when rotated in the other direction.
58. Install the torque converter turbine on the turbine shaft (Fig. 30).
59. Install the snap ring and hook-type seal ring on the turbine shaft (Fig. 30).
60. Install a polyacrylate seal ring in the groove just inside the bolt circle in the converter pump and a second ring on the front of the lockup clutch reaction plate. Be sure the seal is in place inside the groove of the converter pump and plate so they cannot squeeze out during cover assembly.
61. Install the reaction plate (Fig. 30). **If inked balance marks are found on the reaction plate, converter pump, lockup piston and pump cover, assemble and parts with the marks aligned.**
62. **Install the lockup clutch plate on the reaction plate with internal teeth engaging the turbine splined ring. The clutch plate should be soaked in transmission fluid for at least two minutes before installation.**
63. Install the converter pump cover assembly on the converter pump studs. If balance marks are on the cover and pump, align the balance marks (Fig. 31). Install four nuts at 90 degree intervals and torque alternately to 10 ft-lbs to prevent the polyacrylate seals from being forced out of their grooves. Install the remaining nuts and torque all nuts to 19-23 ft-lbs.
64. If any of the parts listed below are replaced during transmission assembly, the dimension A in Fig. 32 must check.

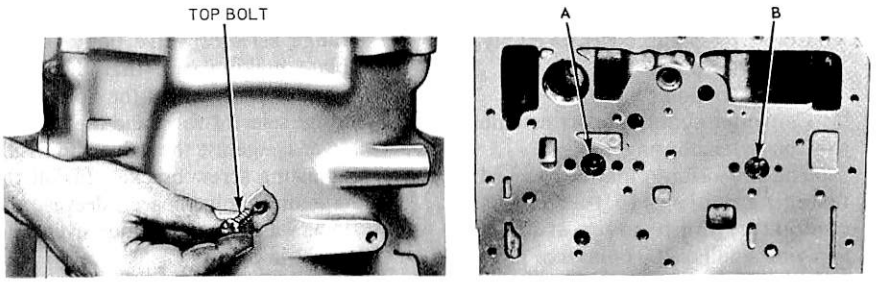

FIG. 28 Diaphragm Bolts—Tightening Sequence

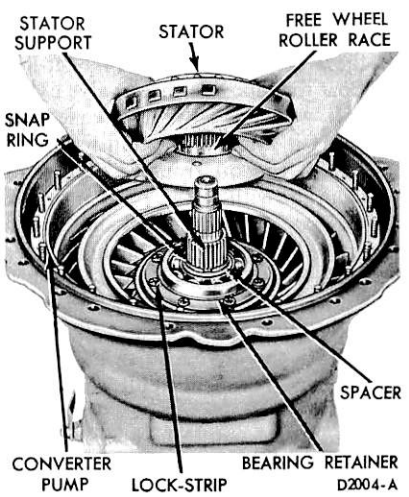

FIG. 29 Converter Stator Installation

Parts replacement which may affect the dimension A are:

Converter pump cover assembly
Converter pump
Converter pump hub
Converter stator support assembly
Converter housing

The dimension A may be checked by fastening a sling to two opposite converter pump cover studs and applying a pull of 100 pounds or more to remove all end play. Do not **lift** the transmission with these studs. While the pull is applied, measure the distance A as shown in Fig. 32. If the dimension is not within 1.572-1.592 inches, remove the spacer retainer(s) and install or remove converter stack control spacers at the pump cover studs as needed. In determining the spacers required, be sure to include the spacer retainer flat thickness (0.015-0.018 inch). The correct dimension should be established at each of the six stud positions. The spacers are serviced as follows:

Thickness Color Code
0.027-0.029 inch Gold
0.045-0.047 inch Silver
0.063-0.065 inch Copper
0.081-0.083 inch Black
0.099-0.101 inch Plain

After the correct spacers have been installed or removed install the spacer retainer(s).

65. If a new control valve body is being installed, the closed throttle stop must be adjusted following the procedures given under Adjustments.
66. Insert the hydraulic retarder valve teflon ball in the transmission housing, install a new gasket on the transmission housing, and then install the hydraulic retarder control valve body assembly install three long (2 1/4-inch) and five short (1 1/4-inch) mounting bolts. Torque the 1 1/4-inch bolts to 15-18 ft-lbs and the 2 1/4-inch bolts to 14-17 ft-lbs.
67. Coat the lube line check valve nylon ball with oil-soluble grease and insert it into the oil transfer plate. Install the oil transfer plate and secure it with the 10 bolts and lock washers. Install the two short bolts at the thin section of the oil transfer plate. Torque the bolts to 8-10 ft-lbs.
68. Position the downshift timing valve body on the oil transfer plate and install the three bolts and lock washers. Torque the bolts to 8-10 ft-lbs.
69. Place the detent shift valve spring in the oil transfer plate and the 3/8-inch diameter steel ball and the 1/2-inch diameter rear pump cut-off valve nylon ball in the range selector valve body. Hold the balls in place with oil-soluble grease. Position the range selector valve body on the plate making sure that the range selector shaft enters the hole in the range selector valve and that the TV lever is against the valve and inside adjusting screw bracket. Install the attaching bolts, spacer sleeves, and lock washers and torque evenly to 48-72 in-lbs.
70. Place a new seal ring on the long tube end of the filter can and install the assembly over the control valve body. Install the attaching bolts. Torque the 3 3/4-inch bolt, located near the end of the long tube, to 4-6 ft-lbs. Torque the remaining two bolts to 8-10 ft-lbs.
71. Install a new oil pan gasket on the transmission housing with the bolt holes properly aligned.
72. If the pan is damaged, replace it.
73. Install the oil pan on the housing. Install the self locking oil pan bolts and torque to 15-18 ft-lbs.
74. Install a new fluid filter element in the oil pan and install the fluid filter retainer and seal ring, a new cover seal ring, and the cover.
75. Remove the transmission from the repair stand and install the covers and gaskets on the power take-off openings. Install the cover bolts and torque them to 15-20 ft-lbs.

CONTROL VALVE BODY

Disassembly

1. Place the control valve body on the bench, flat side down.
2. Remove the screw (68) which retains the signal tube clip (127) (Figs. 33 and 34). Remove the clip and replace the screw finger tight. Remove the screws (88) and (24) that retain the drive and high transfer tube clips (10) and (13).
3. Remove the signal tube (126) and transfer tubes (11) and (12) with the clips attached. Do not remove the clips from tubes (11) and (12).
4. Remove two screws (77) that retain the exhaust regulator valve body (63) to the control valve body (102). Remove the exhaust regulator valve body.
5. Remove the selector valve detent spring (100) and lift the valve body separator plate (97) off the control valve body (102). Remove the 3/8 inch steel detent ball (101) from the valve body.
6. Remove three screws (52) that attach the accelerator plug cover (48). Some models use a bracket (51), spring (50) and ball (49),

FIG. 34 Control Valve—Legend

retained by two screws (52). If the valve body has these parts, remove them. Remove the accelerator plug cover and the accelerator plug (47).

7. Remove the four screws (58) from the regulator cover (57) and remove the cover, lockup knockdown plug (55), accumulator valve spring (56) and the accumulator valve (54).
8. Remove the two screws (59) and (62), and remove the throttle valve retainer (61) from the valve body. **Do not turn or remove the screw (60) from the retainer.** The screw (62) is 3/8 inch long and should not be mixed with 7/16-inch screws. Keep the screw (62) separated from the longer screws to insure that they are installed in the proper locations when the valve body is reassembled.
9. The valve body rear cover is spring-loaded and must be held while the screws are being removed. Remove the remaining three screws (53) that attach the valve body rear cover (46) to the valve body, and remove the rear cover.
10. Remove the intermediate shift valve spring (44), which is exposed when the rear cover is removed.
11. Remove the regulator plug (41) from the rear cover.
12. Remove the throttle valve (98) and spring (99) from the control valve body (102).
13. Remove the manual selector valve (43) from the rear of the control valve body.
14. From the same side of the control valve body, remove the hydraulic retarder regulator plug (42), lockup plug (40), rear pitot (G2) plug (39) and front pitot (G1) splitter plug (36), low-to-intermediate shift valve (38) and the intermediate-to-high shift plug (37).
15. Position the control valve body (102) on the rear surface and remove the two screws (23) that attach the splitter over control valve body (19) to the valve body front cover (32). Remove the splitter over control valve body.
16. Remove the screw (22) that attaches the over control valve cover (21) to the over control valve body. Remove the cover and the splitter over control valve (20) from the body.
17. Remove the splitter shift plug spring (28) and the splitter shift plug (29), which are exposed upon removal of the over control valve body (19) from the front cover (32) (Fig. 33).
18. Remove the three screws (24) and (25) which attach the intermediate-to-high shift valve cover (26) to the valve body front cover (32). Remove the cover (26), intermediate-to-high shift valve spring (27) and intermediate-to-high blocker plug (30).
19. Hold the valve body front cover against the spring pressure and remove the three attaching screws (15). Remove the front cover (32) from the valve body.
20. Remove the 1/4-inch nylon ball (34) that is loose when the front cover is removed. Remove the inhibitor valve (115) and the spring (114) from the cover (32). Remove the main-pressure regulator spring (35) (and secondary spring 35A, used in some models), splitter relay valve spring (111) and lockup shift valve spring (108).
21. Remove the throttle valve plug (33) from the valve body front cover (32).
22. Remove the retainer spring (17) and remove the pump overage valve (18) from the front cover.
23. Remove the two pump overage regulator valve spring retainers (16) and spring (14) from the front cover.
24. Remove the throttle regulator valve, (106), main-pressure regulator valve, (107), lockup shift (109), splitter shift valve, (110), splitter relay valve (113) and intermediate-to-high shift valve (112) from the front of the control valve body (102).
25. Do not remove the reverse-range clutch exhaust pressure regulator valve (105) unless replacement is necessary. Check the operation of the valve while cleaning the valve body. The valve should retain solvent on the side opposite the spring for 15 seconds. If the solvent leaks through sooner, replace the valve.
26. Do not remove the reverse lock-up inhibitor check valve retainer (103) and the 7/32-inch nylon ball (104). If the retainer, the ball or valve body (102) is worn or damaged, all three items must be replaced.
27. On a model which includes a valve guide bracket (89), remove two screws (88), bracket (89), spring (90), and ball (91). Remove the remaining nine screws (88) which attach the exhaust regulator valve body cover (80) to the exhaust regulator valve body (63). Remove the cover. The cover is spring loaded and must be held while the screws are being removed.
28. On a model which does not include the valve guide bracket (89), remove ten screws (88) and one screw (88A). Remove the cover (80). One screw (88A) is shorter, separate it from the longer screws to insure proper installation.
29. Removal of the cover will expose the intermediate exhaust regulator valve spring (94), low-splitter valve spring (93) and lockup cutoff valve spring (81). Remove these springs from the exhaust regulator valve body.
30. Remove the inhibitor plug (116), inhibitor valve (117), inhibitor spring (118), inhibitor spring retainer (119), nut (120) and screw (121). Do not remove the inhibitor spring adjusting screw (121) from the nut. Also, remove the intermediate exhaust regulator valve (96), lockup cutoff valve (82), and low-splitter exhaust regulator valve (95).
31. Remove the extender valve (87), extender valve spring (86), extender valve ball spring (85), and extender valve ball (84). Do not remove the extender valve body (83) and roll pin (92) unless replacement is necessary. Check the operation of the valve while cleaning the extender valve. If replacement is necessary, remove the roll pin and tap out the extender valve body toward the nearest opening (front) of the exhaust regulator valve body (63).
32. Remove the four screws (72) from the trimmer cover (73) and remove the cover from the rear of the exhaust regulator valve body (63) (Fig. 35). **The cover is spring loaded and must be held while the screws are being removed.**
33. Remove the trimmer valve (74), trimmer valve inner (75) and outer (78) springs, trimmer plug (79), trimmer primary spring (71), trimmer stop (70) and trimmer secondary spring (69) from the exhaust regulator valve body (63).
34. Remove the screw (68) retainer (67) and remove low-splitter exhaust regulator stop plug (65) and low splitter exhaust regulator plug (64) (Fig. 35). A model using a set screw (45A) at bottom of the valve body (63) does not use a regulator plug (64). Remove the intermediate exhaust regulator stop plug (66) from the rear of the exhaust regulator valve body (63).
35. Do not remove the pipe plug (76) from the valve body except for inspections or cleaning.
36. Remove the cotter pin (125), flat washer (124), inhibitor spring (123), inhibitor valve (122) from bottom of the body (63).
37. All the valve body parts should be thoroughly cleaned in cleaning solvent and dried with compressed air. All passages must be completely free of dirt and obstructions. Use a soft bristle brush. **Do not use abrasives or scraping tools.** After

cleaning, place the parts on clean paper and cover with paper to keep the dust out.

38. Inspect all the parts closely for wear, breaks, cracks, burrs, and dirt. Burrs may be removed with a soft abrasive stone. **Do not destroy the sharp edges of valves. The valves are designed with sharp edges to prevent them from sticking in their bores.**
39. Inspect all the springs and check them for free length. Correct performance of the transmission depends upon the good condition of springs. **Refer to specifications section for valve body spring identification and specifications.**
40. Before assembly, try all the valves in their bores. When parts are clean and dry, the valves should move in their bores by their weight only. Do not force them into the bores.
41. Reclean the parts, if necessary after inspection. Lubricate the parts with specified fluid.

Assembly

1. Install the intermediate exhaust regulator stop plug (66), small diameter first, in the exhaust regulator valve body (63), (Fig. 35).
2. Install the low splitter exhaust regulator plug (64).

Some models do not use a plug in this location. Such models are identified by the presence of a socket-head set screw (45A).

3. Install the low splitter exhaust regulator stop plug (65), small diameter first.
4. Install the plug retainer (67) and screw (68) finger tight.
5. Install the trimmer secondary spring (69), trimmer stop (70), trimmer primary spring (71) and plug (79).
6. Install the trimmer return inner and outer springs (75) and (78) and trimmer valve (74).
7. Install the trimmer cover (73) and four screws (72). Torque the screws to 24-36 in-lbs.
8. If the pipe plug (76) was removed, reinstall.
9. Install the inhibitor valve (122), inhibitor spring (123), flat washer (124) and new cotter pin (125) in the bottom of the exhaust regulator body (63).
10. If the extender valve body (Fig. 36)

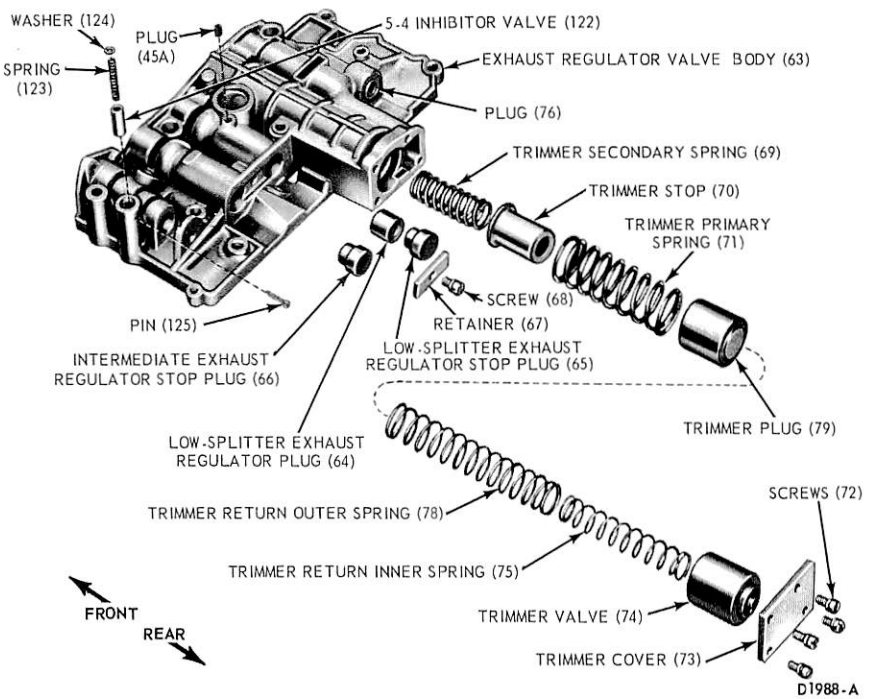

FIG. 35 Exhaust Regulator Valve Body—Rear View

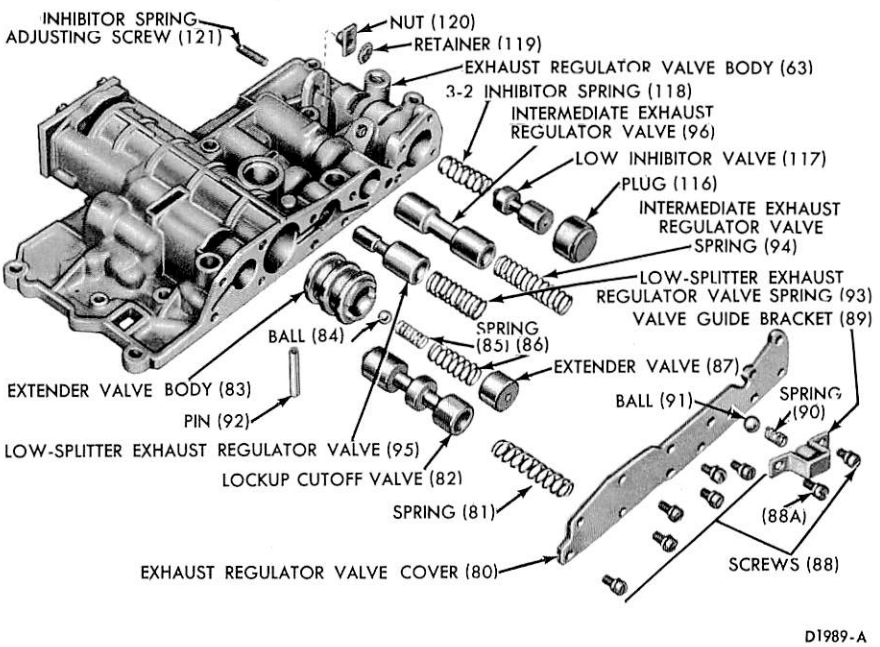

FIG. 36 Exhaust Regulator Valve Body—Front View

(83) was removed, install it with the roll pin (92). Press the pin (92) into the valve body (63) until it is slightly below the flat surface of the body.

11. Install the low splitter and intermediate exhaust regulator valves (95) and (96).
12. Install the low splitter and intermediate exhaust regulator springs (93) and (94).
13. Install the extender valve ball (84), springs (85) and (86) and extender valve (87), recessed end first.
14. Install the lockup cutoff valve (82) and spring (81).
15. Install the adjusting screw (121) and nut (12) (assembled) through slot into small end of inhibitor bore in cover (63). Also install the inhibitor spring retainer (119) with recessed center over the end of the adjusting screw (121), inhibitor spring (118), inhibitor valve (117) and inhibitor plug (116).
16. Install the exhaust cover (80) and nine regulator valve screws (88).
17. On a model which uses a valve guide bracket (89), trimmer ball regulator spring (90) and ball (91), install these parts and attach them with two screws (88).
18. On a model which does not use a valve guide bracket, trimmer ball regulator (89), spring (90) and ball (91), install one screw (88) in the hole at the right end of cover (80) and one screw (88A) in the remaining threaded hole. The short (3/8-inch) screw (88A) must be installed in the fifth threaded hole from the right end of the cover when valve guide bracket (89) is not used.
19. Torque the cover screws to 24-36 in-lbs.

Do not install the screw that attaches the drive transfer tube clip at this time.

20. Install the throttle regulator, main pressure, lockup shift, splitter shift, intermediate-to-high and splitter relay valves (106), (107), (109), (110), (112), and (113) in their respective bores and in the positions illustrated in the valve body (102), (Fig. 37).
21. Install the lockup shift valve spring (108) on the stem of the valve (109).
22. If removed for replacement, install a new reverse-range clutch exhaust regulator valve (105) in the control valve body (102).
23. Install the nylon ball (34) (Fig. 38)

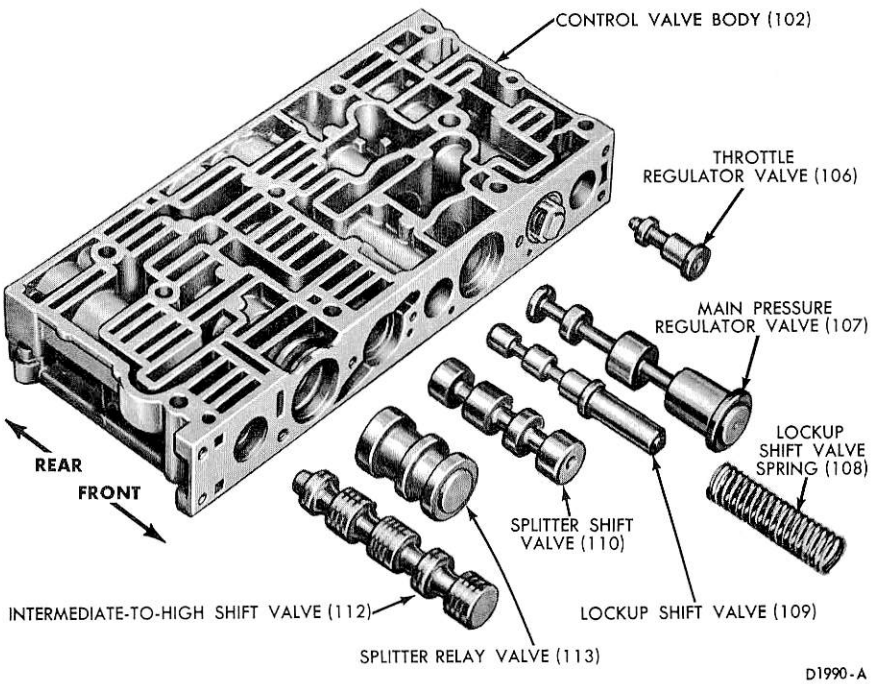

FIG. 37 Control Valve Body—Front View

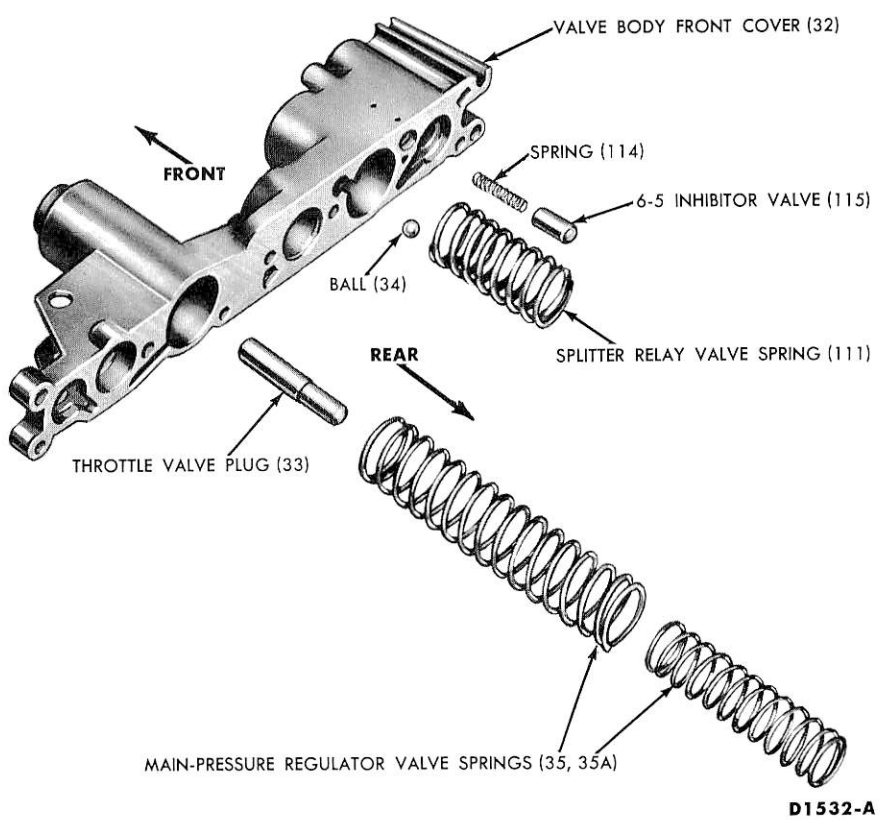

FIG. 38 Control Valve Body Front Cover—Rear View

in the small bore at the upper left of the bore which receives the splitter relay valve spring. Hold it in place with oil-soluble grease.

24. Install the throttle valve plug (33), large diameter first, in the small bore at the bottom of the recess which receives the main-pressure regulator valve spring (35).
25. Install the main pressure regulator primary and secondary springs (35) and (35A). Some models do not include the secondary spring (35A).
26. Install the inhibitor valve (115) and the inhibitor valve spring (114) in the valve body front cover (32).
27. Install the valve body front cover (Fig. 39), and its related components on the control valve body (102).
28. Comprss the springs and install the three screws (15). Do not tighten the screws at this time.
29. Install the intermediate-to-high blocker plug (30) (Fig. 40) and shift valve spring (27).
30. Install the cover (26), two long screws (25) and one short screw (24) but do not tighten the screws at this time.
31. Install the splitter shift plug (29) in the valve body front cover (Fig. 41).
32. Install overcontrol valve (20) in the overcontrol valve body (19).
33. Install the cover (21) on the overcontrol valve body (19) and retain it with one screw (22).
34. Install the splitter shift plug spring (28) in the recessed end of the overcontrol valve (20), previously installed in the body (19).
35. Install the splitter shift plug spring (28) overcontrol valve body (19), valve (20), over (21) and screw (22) on the valve body front cover. Install two screws (23), but do not tighten them at this time.
36. Install the intermediate-to-high shift plug (37) (Fig. 42) low-to-intermediate shift valve (38), front splitter plug (36), rear-splitter shift plug (39), lockup plug (40) and the hydraulic retarder regulator plug (42).
37. Install the manual selector valve (43), the throttle valve spring (99) and throttle valve (98).
38. Install the regulator plug (41) and intermediate-to-low shift valve spring (44) in the valve body rear cover (46) (Fig. 43).
39. Install the valve body rear cover (46) and its assembled components onto

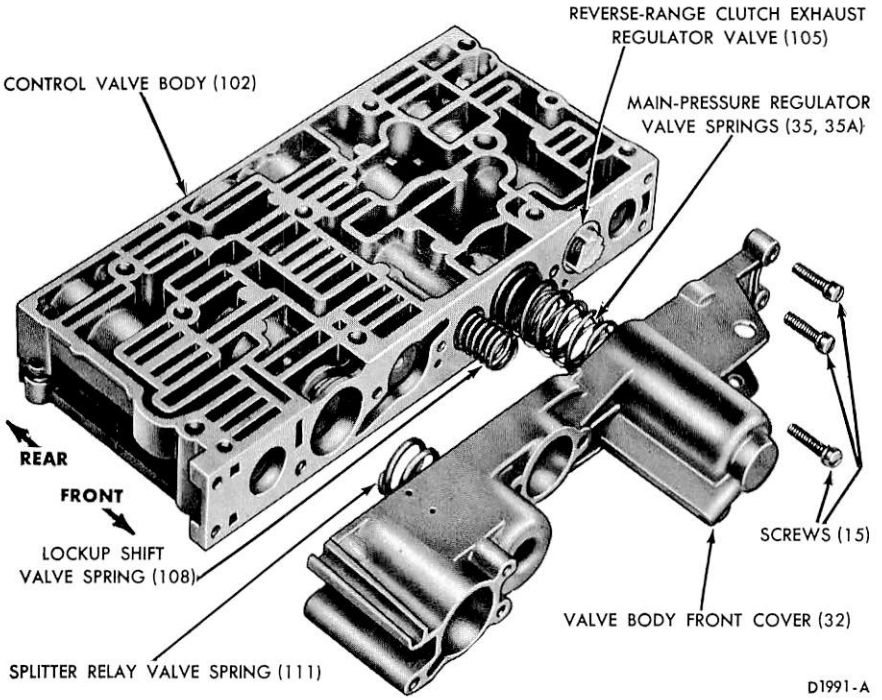

FIG. 39 Control Valve Body and Front Cover

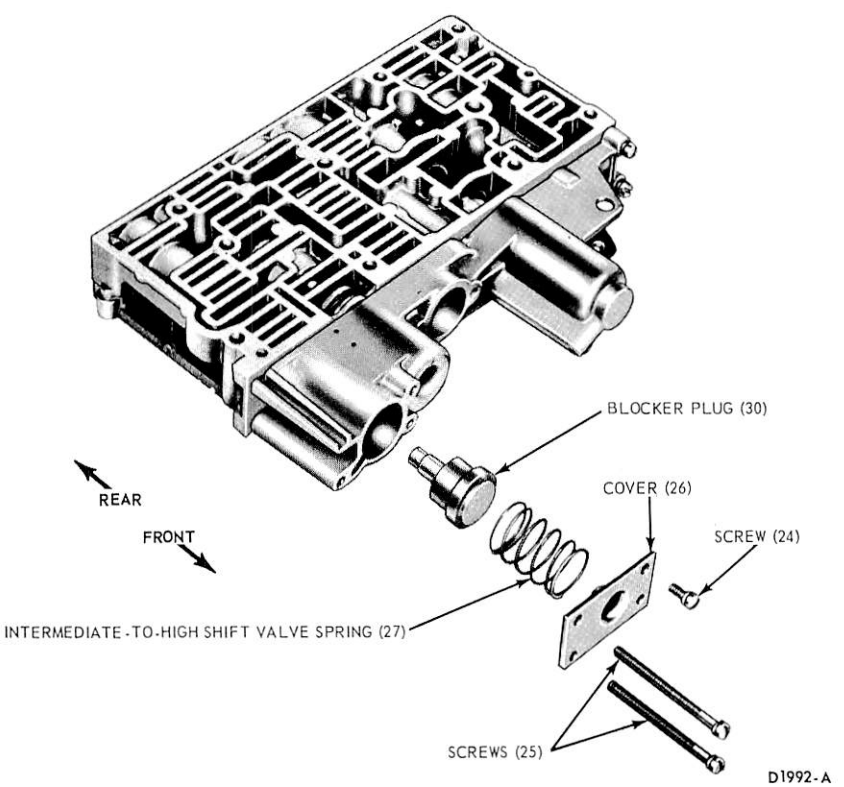

FIG. 40 Intermediate-to-High Shift Valve Components

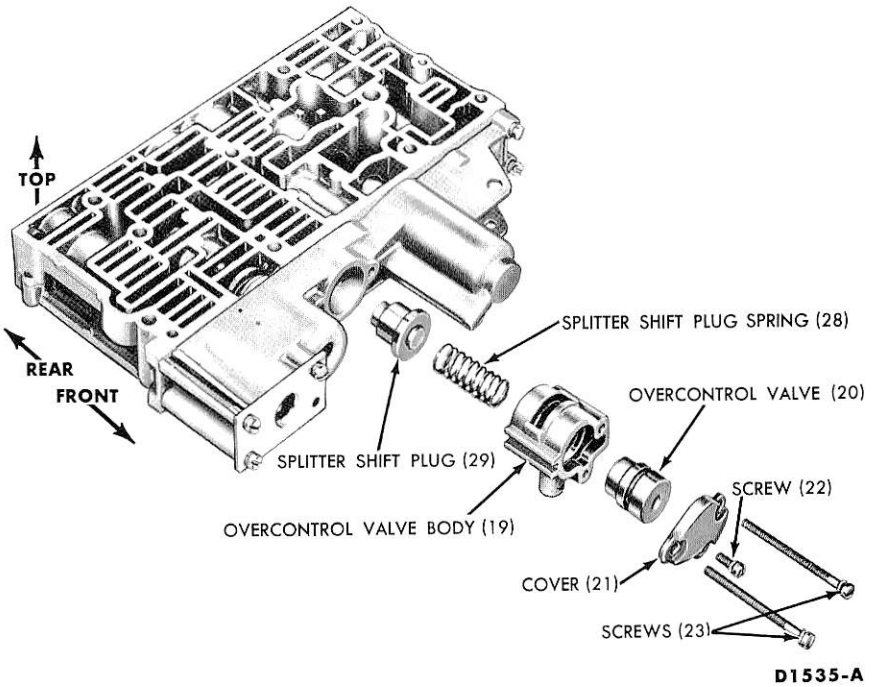

FIG. 41 Splitter Overcontrol Valve Components

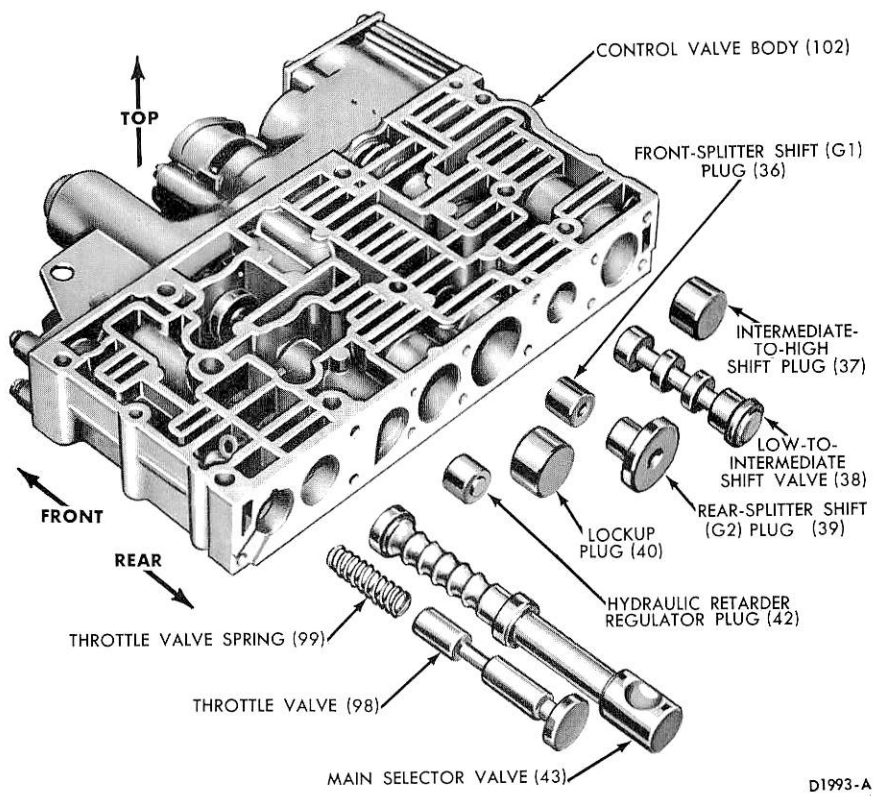

FIG. 42 Control Valve Body—Rear View

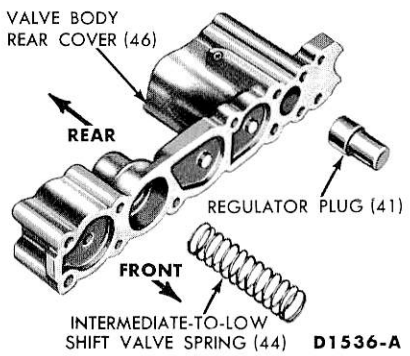

FIG. 43 Control Valve Body Rear Cover—Front View

the assembled valve body (Fig. 44).

40. Install the three screws (53) which retain the valve body rear cover (46). Do not install the screw (59) that attaches the throttle valve retainer (61). Do not tighten the screws at this time.
41. Install the throttle valve retainer (61) and secure it with two screws (62) and (59). Do not tighten the screws at this time.
42. Install the lockup knockdown plug (55) (Fig. 45). Install the plug by inserting the small end of the plug into the housing.
43. Install the accumulator valve (54). Make sure the open end of the valve is outward, for the spring to fit into.
44. Install the accumulator valve spring (56) and regulator cover (57).
45. Secure the regulator cover (57) with four screws. Torque the screws (58) to 24-36 in-lbs.
46. Install the accelerator plug (47) and cover (48) (Fig. 46).
47. On a model which includes a ball (49), trimmer ball regulator spring (50) and the valve guide bracket (51), install these parts and secure them with two screws (52). Install a third screw (52) to secure the cover (48). Do not tighten the screws at this time.
48. On a model which does not include the ball, spring, and bracket, install three screws (52) to secure the accelerator plug cover (48). Do not tighten the screws at this time.

Install the selector valve ball (101) and spring (100) in the hole which registers with the manual selector valve indentations (Fig. 33).

49. Install the valve body separator plate (97) on the valve body assembly (Fig. 33).

50. Install the assembled regulator valve body and secure it with two screws (77). Torque the screws to 24-36 in-lbs.
51. Place the control valve body, flat (top) side downward, on a flat surface. Check to determine if the end covers project below the valve body. Tap the valve body downward to correct any such projection. Torque all screws at the front and rear of the valve body to specification. This check is important. The valve body must seat tightly against the oil transfer plate, on which is mounts, to prevent fluid leakage.
52. Assemble a spring retainer (16) to each end of pump overage valve spring (14) (Fig. 33). Compress the spring and install it between the ribs on the valve body front cover (32). Install pump overage valve assembly (18) and fasten it with retainer spring (17). The seat face of the valve assembly must protrude at least 0.005 inch beyond the valve body mounting plate to assure seating of the valve against the oil transfer plate.
53. Install the high-transfer tube (12) with the clip (13). Fasten the clip with its attaching screw (24) (Fig. 33).
54. Install the drive-transfer tube (11) with its clip (10). Fasten the clip with a screw (88).
55. Install the signal tube (126) and tube clip (127) with a screw (68).
56. Torque the screws (24), (68) and (88) to 24 to 36 in-lbs.

OIL TRANSFER PLATE

Disassembly

1. Remove the two screws which attach the converter lube supply cover to the oil transfer plate and remove the cover.
2. Remove the two screws which attach the converter pressure regulator valve retainer to the oil transfer plate. Remove the retainer, spring, seat, and the steel ball.
3. The low-range clutch exhaust regulator valve and orifice cup should not be removed unless it is to be replaced. Check the operation of the valve while cleaning the transfer plate. The valve should hold the cleaning solvent on the side opposite the spring for at least 15 seconds.

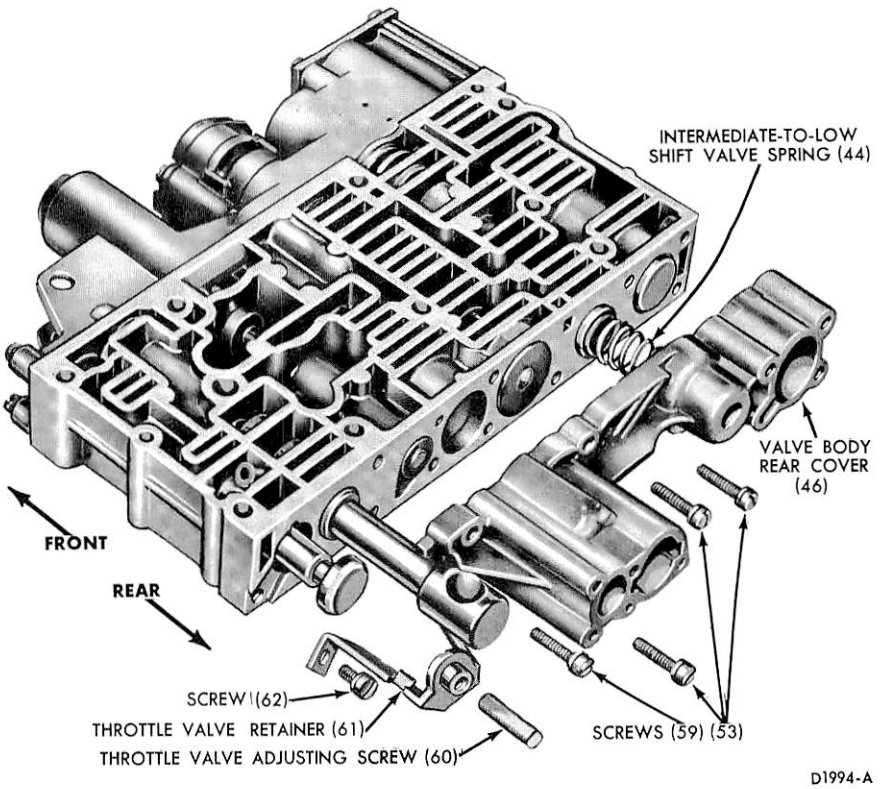

FIG. 44 Control Valve Body Rear Cover—Rear View

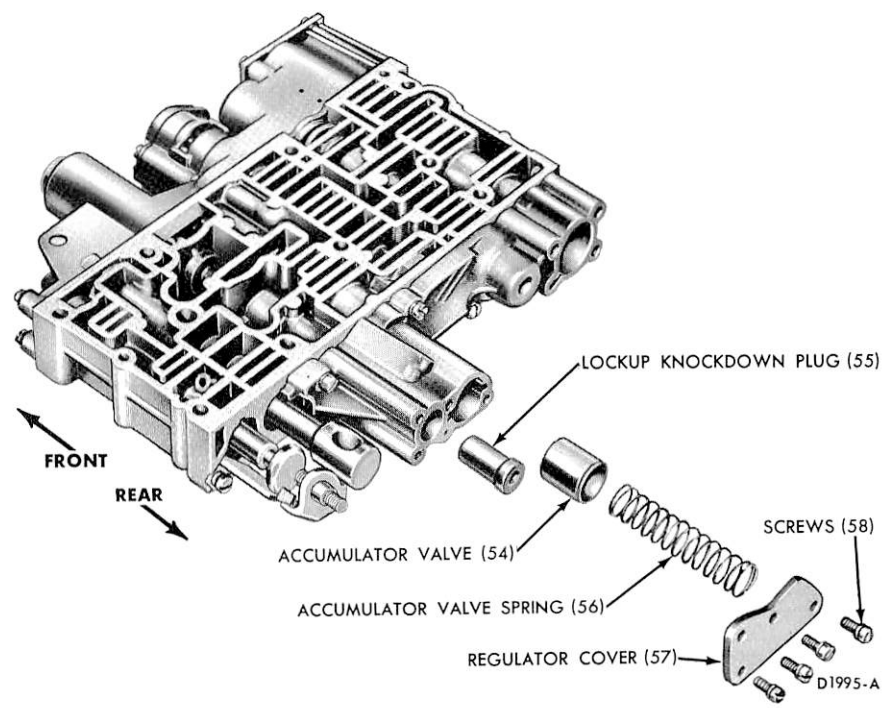

FIG. 45 Lockup Knockdown Plug and Accumulator Valve

Assembly

1. When replacing the low-range clutch exhaust regulator valve and orifice cup, press the cup, convex side first, into the recess of the exhaust regulator valve. Be sure the cup is entered.
2. Press the regulator valve, wide end first, into its bore in the transfer plate. Exert pressure only on the shoulder of the valve next to the closed portion of the spring cover. Do not let the cup slide from its recess while the valve is being installed. When the valve is in place, the spring cover must be flush with or slightly below the outer surface of the transfer plate.
3. Install the lube supply ball seat in the lube supply cover. Install the lube supply cover with the ball seat end toward the rear. Torque the screws to 24-36 in-lbs. **The nylon ball is installed from the other side of the oil transfer plate when the plate is assembled to the transmission housing.**
4. Assemble the steel ball, seat, spring, and converter pressure regulator valve retainer to the oil transfer plate and install the two screws. Torque the screws to 24-36 in-lbs.

RANGE SELECTOR SHAFT AND THROTTLE CONTROL LEVERS

When removing or installing the selector and throttle levers, be careful not to push the shafts back inside the transmission housing. When this happens, the shafts lose their index location with their corresponding valve of the control valve body in the housing. It will then be necessary to remove the transmission oil pan and reposition the shafts.

Disassembly

1. Place the selector lever in the 3-6 detent position.
2. Straighten the TV lever washer on the TV shaft. Remove the TV nut and washer and remove the lever from the shaft. **Always hold the lever when removing or installing lever retaining nuts. Do not use the mechanical stop inside the transmission as the reaction member for removal of lever retaining nuts. The stop is used for making a calibrated adjustment and could be damaged.**
3. Straighten the shift selector lever washer on the selector shaft. Remove the nut and washer and remove the lever.
4. Remove the O-ring seals from the shafts.

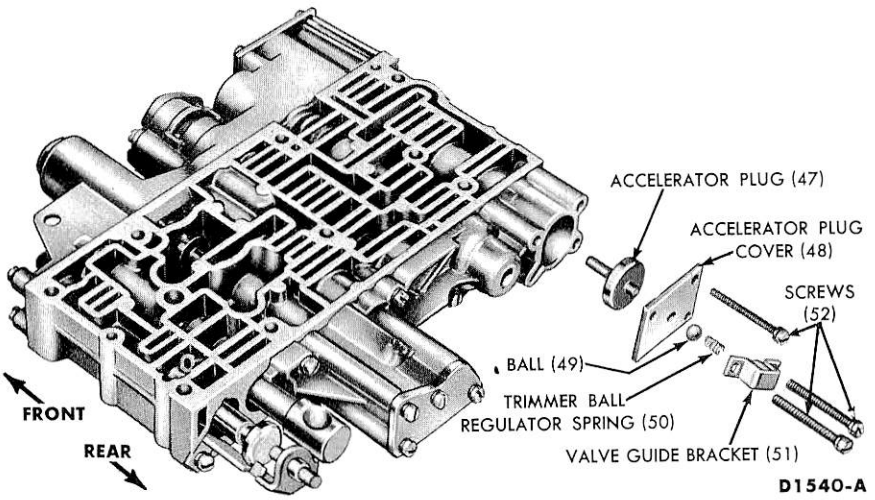

FIG. 46 Accelerator Plug and Cover

Assembly

1. Install a new O-ring seal on the selector shaft.
2. With the selector shaft in the 3-6 detent position, hold the shaft with a pair of pliers and slide the selector lever onto the shaft far enough for the retaining nut to be installed.
3. Install the washer and retaining nut. Then, grasp the end of the selector lever and while pulling out (away from the transmission), tighten the retaining nut to 14-17 ft-lbs torque. Bend the washer against a flat on the nut.
4. Before installing the TV lever, determine if the transmission has a long or short stroke TV configuration. On transmissions with a long stroke TV, the lever will have an arc travel of 32 degrees from stop to stop. The short stroke will have an arc travel of 16 degrees from stop to stop.
5. Install a new O-ring seal on the TV shaft.
6. If the transmission has a long stroke TV configuration, leave the selector lever in the 3-6 detent position. If the transmission has a short stroke configuration, place the selector lever in the reverse detent position.
7. With the selector lever in the proper detent, hold the TV shaft with a pair of pliers and slide the TV lever onto the shaft far enough for the retaining nut to be installed.
8. Install the washer and retaining nut. Then, grasp the end of the TV lever and while pulling out (away from the transmission) tighten the nut to 14-17 ft-lbs torque. Bend the washer against a flat on the nut.

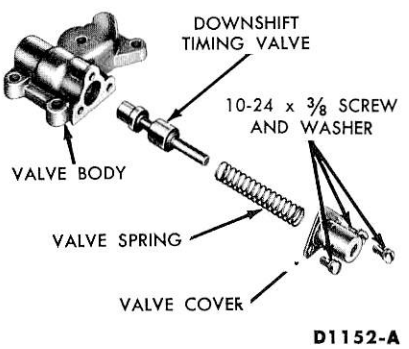

FIG. 47 Downshift Timing Valve

DOWNSHIFT TIMING VALVE

Disassembly

1. Remove the downshift timing valve cover (Fig. 47).
2. Remove the spring and downshift timing valve.

Assembly

1. Insert the valve in the body and place the spring on the stem of the valve.
2. Install the valve cover over the spring and torque the three screws to 24-36 in-lbs.

HYDRAULIC RETARDER CONTROL VALVE

The retarder valve stop pin in the retarder valve has been changed from a tight fit to a loose fit in the valve body for ease of removal or installation. The loose stop pin can easily drop out of the valve body when it is separated from the transmission if the valve is held inward.

The absence of the stop pin will

result in improper oil circulation within the transmission, resulting in overheating and damage to the transmission. The valve will still function properly without the pin and will give no indication that the pin is missing.

Care must be exercised at the time of installation of the valve on the transmission to make certain that the pin is properly located in the retarder valve body.

Disassembly

1. Using vise-grip pliers, twist the lubrication regulator valve retainer out of the retarder control valve body (Fig. 48).
2. Remove the lubrication regulator valve spring and regulator valve (steel) ball.
3. Press inward on the valve to relieve the spring tension, then, lift out the retarder valve retaining pin.
4. Strike the retarder valve stem several sharp blows with a mallet. The rebound of the valve, after being driven against its spring, will force out the oil seal (Fig. 49).
5. Remove the retarder valve assembly, oil seal and return spring.
6. The spring pin and clevis pin need not be removed unless replacement is necessary.

Assembly

1. If the clevis pin and spring pin were removed, replace them.
2. Install the retarder valve return spring and retarder valve assembly in the retarder control valve body.
3. By inserting a thin fiber strip into one of the valve body ports while the valve is compressed against the spring, hold the valve in its inward position. From the ported side of the valve body, place the pin in the valve body. Remove the fiber strip.
4. Press the seal into the housing until the top of the seal is 1/16-inch above the body. **Do not press the seal flush with the body or against the pin. Be sure there are no sharp edges or burrs on the slotted area of the retarder control valve.**
5. Install the lubrication regulator valve (steel) ball, spring and retainer. Press the retainer flush with, or to 0.030 inch below, the valve body surface.

CONVERTER PUMP COVER AND LOCKUP CLUTCH

Disassembly

1. Remove the lockup clutch reaction plate (Fig. 50) from the converter pump cover, and lift out the clutch plate. If necessary, tap the edge of the cover against a wooden block to remove the reaction plate.
2. Remove the seal ring from the front flange of the reaction plate.
3. Remove the snap ring which holds the lockup clutch piston in the pump cover.
4. Remove the piston from the pump cover by tapping the edge of the cover against a wooden block.
5. Remove the piston inner seal and seal retainer (if loose) from the pump cover hub.
6. Remove the seal ring from the outer groove of the piston.
7. Clean all of the converter cover and lockup clutch parts, and inspect them for wear or damge. Replace all parts that are worn beyond the specified limits or that are damaged.

Check the orifice in the lockup piston. This orifice is drilled through one of the dowel holes.

The converter pump cover bushing can be replaced if it is excessively worn.

Assembly

1. Install the seal ring (Fig. 50) in the outer groove of the lockup clutch piston. Then apply a light coat of oil to the seal.
2. Install the piston inner seal retainer and seal on the pump cover hub.
3. Install the piston in the converter pump cover so that the dowel holes in the piston engage the dowels in the cover (Fig. 31). The balance marks on both parts must also be aligned. To align the parts correctly, place a heavy pencil mark in line with a dowel on the bolt circle of the cover, then match this mark with another mark on the piston in line with a dowel hole on the reverse side. If the dowels do not enter the dowel holes, the lockup clutch will not disengage and the converter will not function.
4. Install the snap ring. If the piston does not push far enough into the pump cover to install the snap ring, compress the piston by hand pressure.

CONVERTER PUMP

Disassembly

1. Remove the hook-type seal ring from the hub.
2. Flatten the tabs on the hub bolt lock strips (Fig. 50) and remove the bolts, lock strips, and bearing retainer.
3. Remove the hub and bearings from the pump. Then lightly tap the bearing from the hub.
4. Remove the hub gasket.
5. Tap out all damaged or worn converter pump to converter cover bolts. Only damaged bolts should be removed from the pump. Do not lose the positions of the balance weights.

Assembly

1. If any converter pump bolts were removed, insert the new bolts around the outer diameter of the pump, and press them into place.
2. Install a new gasket on the hub. **Do not use a gasket sealer.** If the pump hub is to be used for prefitting the front pump oil seal, do not install the seal ring at this time.
3. Install the bearing in the hub, and position the hub in the pump.
4. Install the bearing retainer on the hub, align the mounting holes, and install new lock strips. Install the attaching bolts and torque them to 9-11 ft-lbs. Be sure to bend the pointed tab of lock strips up to lock the bolts.

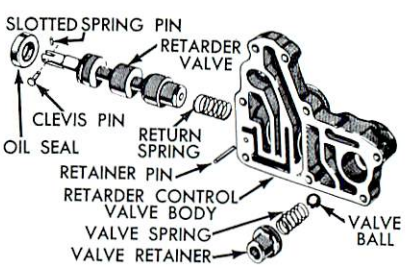

FIG. 48 Hydraulic Retarder Control Valve Exploded View

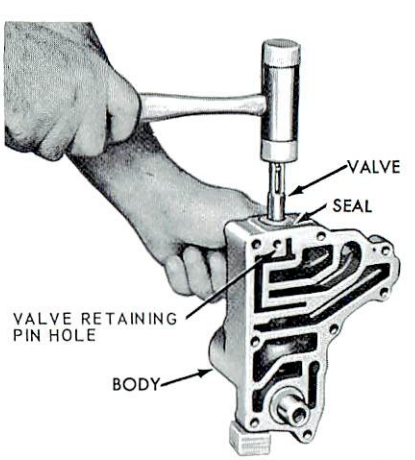

FIG. 49 Removing Hydraulic Retarder Valve Seal

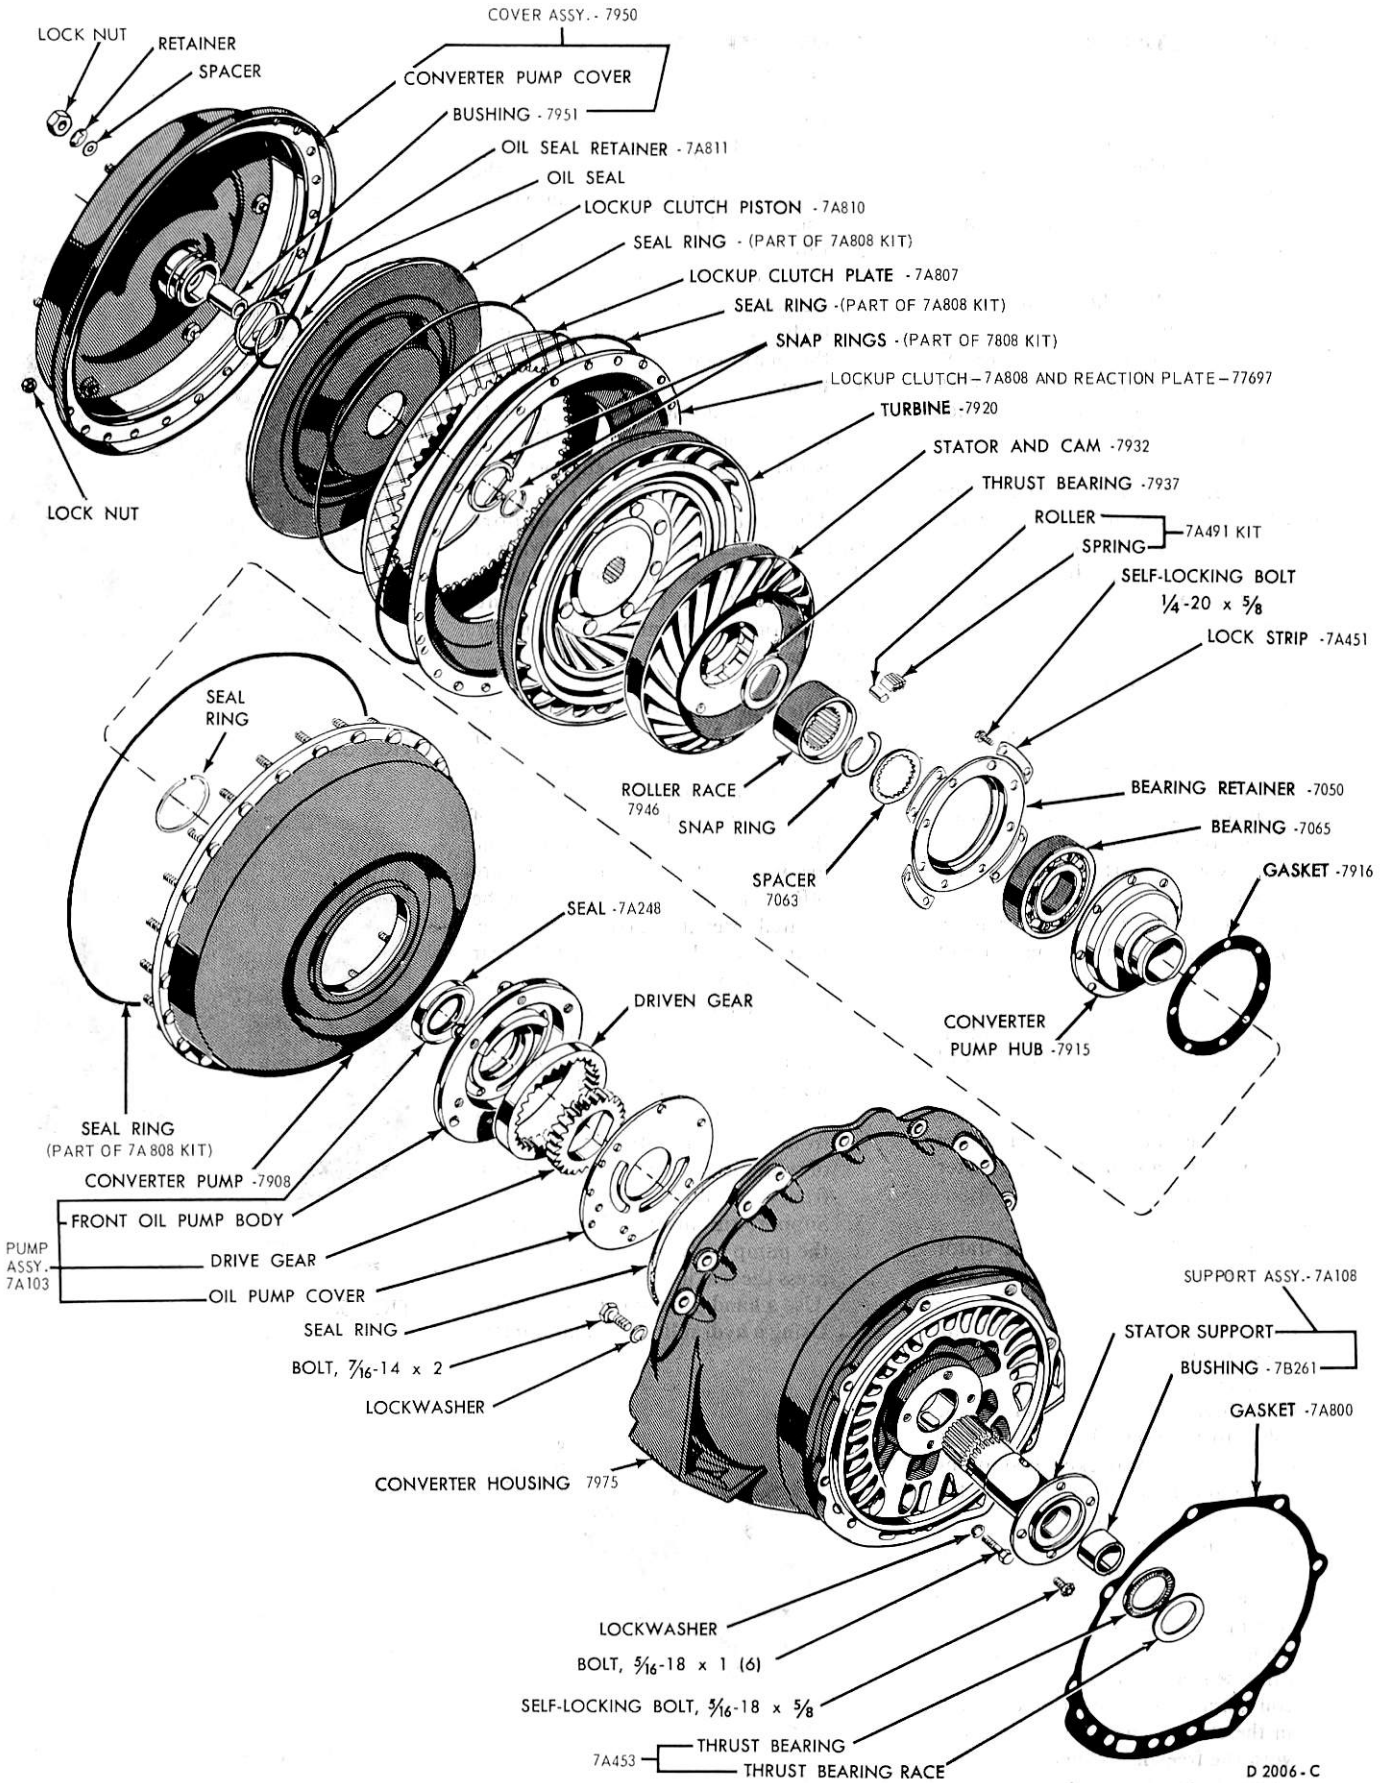

FIG. 50 Torque Converter, Lockup Clutch and Front Pump

CONVERTER STATOR

Disassembly

1. Place the stator on a clean bench, with the freewheel roller race facing upward.
2. Remove the roller race by rotating it clockwise while lifting it out of the stator.
3. Remove the 10 rollers and springs from the stator.
4. Inspect the stator for cracks or excessive wear, and check the rollers and springs for nicks, burrs, or other damage. Replace the parts as needed.

Thoroughly clean and lubricate the roller thrust bearing in the stator. Then rotate the bearing while pressing upon the rear thrust washer. If the bearing does not rotate smoothly without roughness or binding, replace it as follows:

5. Remove the old bearing from the stator.
6. Clean the bore and thrust face of the stator, and make sure that both are free of burrs or raised metal.
7. With the seamed edge of the thrust bearing outer shell facing the stator thrust washer, start the bearing into its bore.
8. Using tool (T57T-7003-A7) with a diameter slightly larger than that of the thrust bearing and which is smooth and flat on the side that contacts the bearing outer shell, press the bearing into its bore until the upper edge of the outer shell is 0.025-0.035 inch above the surface next to the outside diameter of the bearing. **Do not bottom the outer shell in the stator.**

Assembly

1. Apply oil-soluble grease to the stator cam pockets, and place the freewheel roller springs in the openings with the open end facing the stator bore at the end against the roller (Fig. 51)
2. Compress the springs to allow the roller to be inserted in the shallow end of each cam pocket. Install one spring and roller in each of the ten pockets in the stator.
3. Install the freewheel roller race in the stator with the counterbored side facing away from the stator needle bearing. Rotate the race clockwise while installing it. When the race is fully seated, twist it firmly in a counterclockwise direction to lock it in the stator. Then place the stator with the freewheel inner race facing upward until installation.

CONVERTER HOUSING AND FRONT PUMP

Disassembly

1. Remove the bolts and lock washers that hold the front pump on the housing, and remove the pump body and gears (Fig. 52).
2. Lift the front pump cover and seal ring out of the converter housing.
3. Remove the gears from the pump body. Drive the seal out the front of the pump body.
4. Remove the bolts that hold the converter stator support assembly on the converter housing. Using a wood block, drive the support from the housing (Fig. 53).

The converter stator support bushing and the roller thrust bearing at the end of the stator support can be replaced. Refer to Removal and Installation for information on bushing replacement.

Assembly

1. Align the holes in the stator support with the holes in the converter housing by installing two headless bolts in the converter housing. Place a new support through the rear of the converter housing and over the headless bolts. The bolt holes are offset and the support cannot be rotated after it is driven into place. Using a wood block against the rear of the support, drive the support tightly against the housing (Fig. 54). Remove the two headless bolts. Then install the attaching bolts and torque them to 17-20 ft-lbs.
2. Coat the outer diameter of a new front pump seal with a very thin film of white lead. Start the seal into the front bore of the pump body.
3. Support the machined rear face of the pump body on a flat surface and press the seal into the body (Fig. 55). **Use a hand press for this operation. Using a hydraulic press may damage**

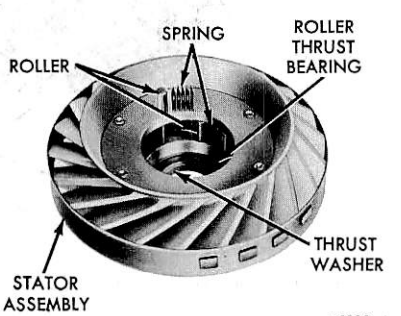

FIG. 51 Converter Stator

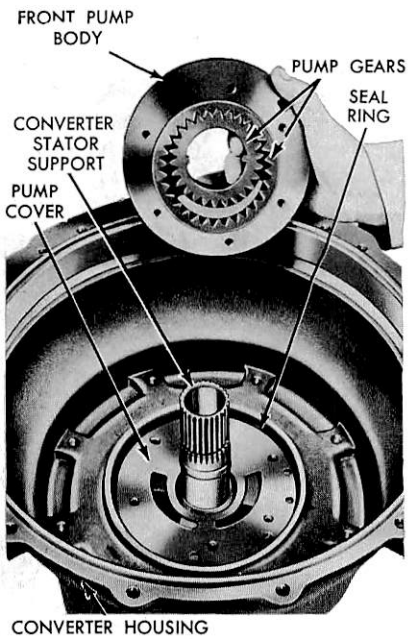

FIG. 52 Front Pump Body Removal

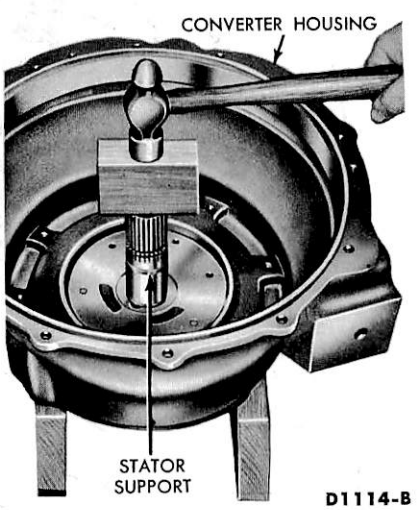

FIG. 53 Converter Stator Support Removal

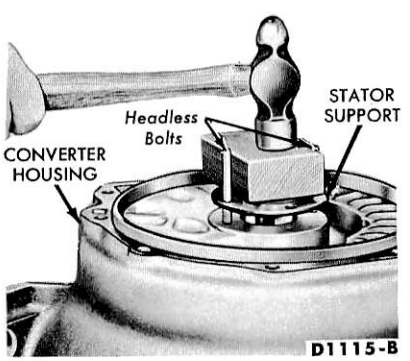

FIG. 54 Converter Stator Support Installation

the seal. Press the seal into the pump body until the distance measured from the front surface of the seal to the rear machined surface of the pump body is 1.595-1.605 inches.

4. Place the pump gears in the pump body. Position the pump cover and install two guide bolts (Tool J3387-2) in the body. Install the square section O-ring seal round the pump cover.
5. Place the pump in front of the converter housing and insert the guide bolts through the proper holes in the housing and install four bolts with lock washers through the rear of the converter housing into the pump body. Remove the guide bolts and install the two remaining bolts with lock washers. Torque all the bolts to 15-18 ft-lbs.
6. With the hook-type seal ring removed from the converter pump hub, align the flats on the hub with the front pump drive flats and insert the hub through the seal. Leave these parts assembled in this manner until ready for final assembly.
7. Install the needle roller bearing and needle bearing assembly. Be sure the rollers in the assembly are facing down.

SPLITTER MECHANISM, HIGH-RANGE CLUTCH, AND POWER TAKE-OFF DRIVE GEAR

Disassembly

1. Remove the low-range sun gear snap ring (Fig. 56), then remove the low-range sun gear and intermediate range sun gear.
2. Grasp the unit with the fingers under the high-range clutch and the thumbs over the low-splitter clutch friction plate to prevent it falling apart, then place it on blocks.
3. Remove the thrust washer from the front of the splitter planetary carrier assembly, then remove the snap ring which holds the splitter planetary carrier assembly to the splitter output shaft assembly (Fig. 57).
4. Remove the splitter planetary carrier assembly and thrust washer in front of the splitter sun gear.
5. Remove the high-splitter clutch and low-splitter clutch friction plate on models having an 8-tanged low-splitter clutch plate (Fig. 58).
6. Remove the high-splitter clutch plate retaining snap ring, then remove the high-splitter clutch back plate.
7. In 3-plate clutch assemblies, remove the two internal-splined plates and one externalsplined plate. In 5-plate clutch assemblies, remove three internal-splined plates and two external-splined plates. Remove the low-splitter clutch friction plate on models having a 6-tanged plate.
8. Place the high-splitter clutch housing in a press, support the rear of the housing, compress the piston Belleville return spring, then remove the snap ring (Fig. 59). Remove the housing from the press. **When releasing the Belleville spring pressure, be sure that the spring does not catch in the snap ring groove.**
9. Remove the Belleville spring and tap the forward edge of the clutch housing against a wood block to remove the high-splitter piston.
10. Remove the teflon seal ring and seal ring expander from the piston. Remove the hook-type seal ring from the housing.
11. Remove the thrust washer and the two hook-type seal rings from the diaphragm (Fig. 60).
12. Remove the splitter output shaft assembly. **Remove the splitter output shaft slowly so that the hook ends of the seal rings do not break off. Remove the two wire snap rings and the three hook-type seal rings, if necessary.**
13. Support the rear of the high-range clutch housing assembly in a press and compress the low-splitter clutch piston Belleville spring, using the tool shown in Fig. 61, then remove the snap ring. Carefully release the pressure on the Belleville spring to keep the inner edge of the spring from catching in the snap ring groove. Do not attempt to lift the diaphragm from the assembly at this time, as the vanes in the front-fluid velocity governor, may be damaged by the pitot tube.
14. Remove the assembly from the press and lift out the Belleville spring.
15. Remove the low-splitter clutch piston from the high-range clutch diaphragm and remove the teflon seal ring and seal ring expander from the piston. Remove the hook-type seal ring from the diaphragm. Do

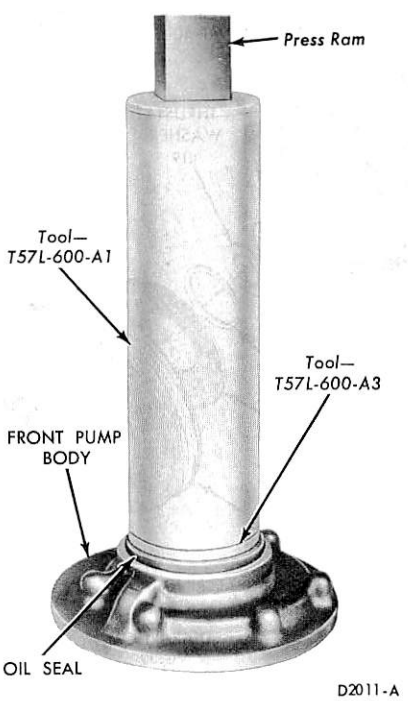

FIG. 55 Front Pump Seal Installation

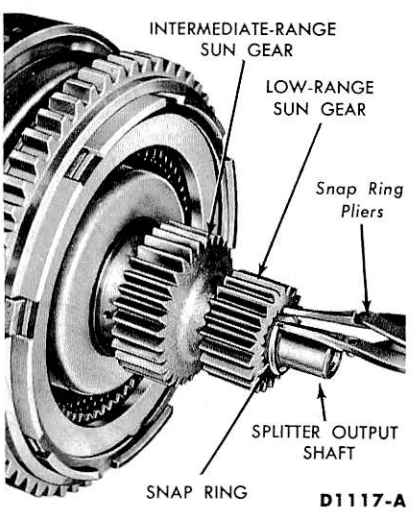

FIG. 56 Low-Range Sun Gear Snap Ring Removal

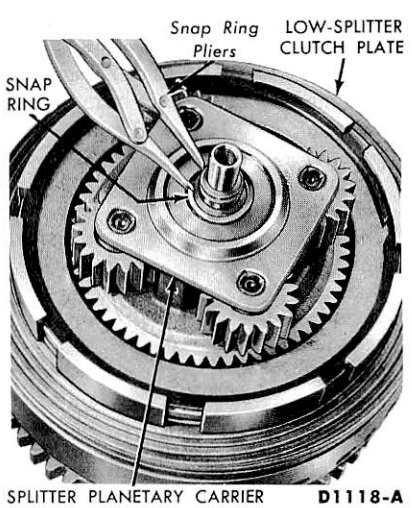

FIG. 57 Splitter Planetary Snap Ring Removal

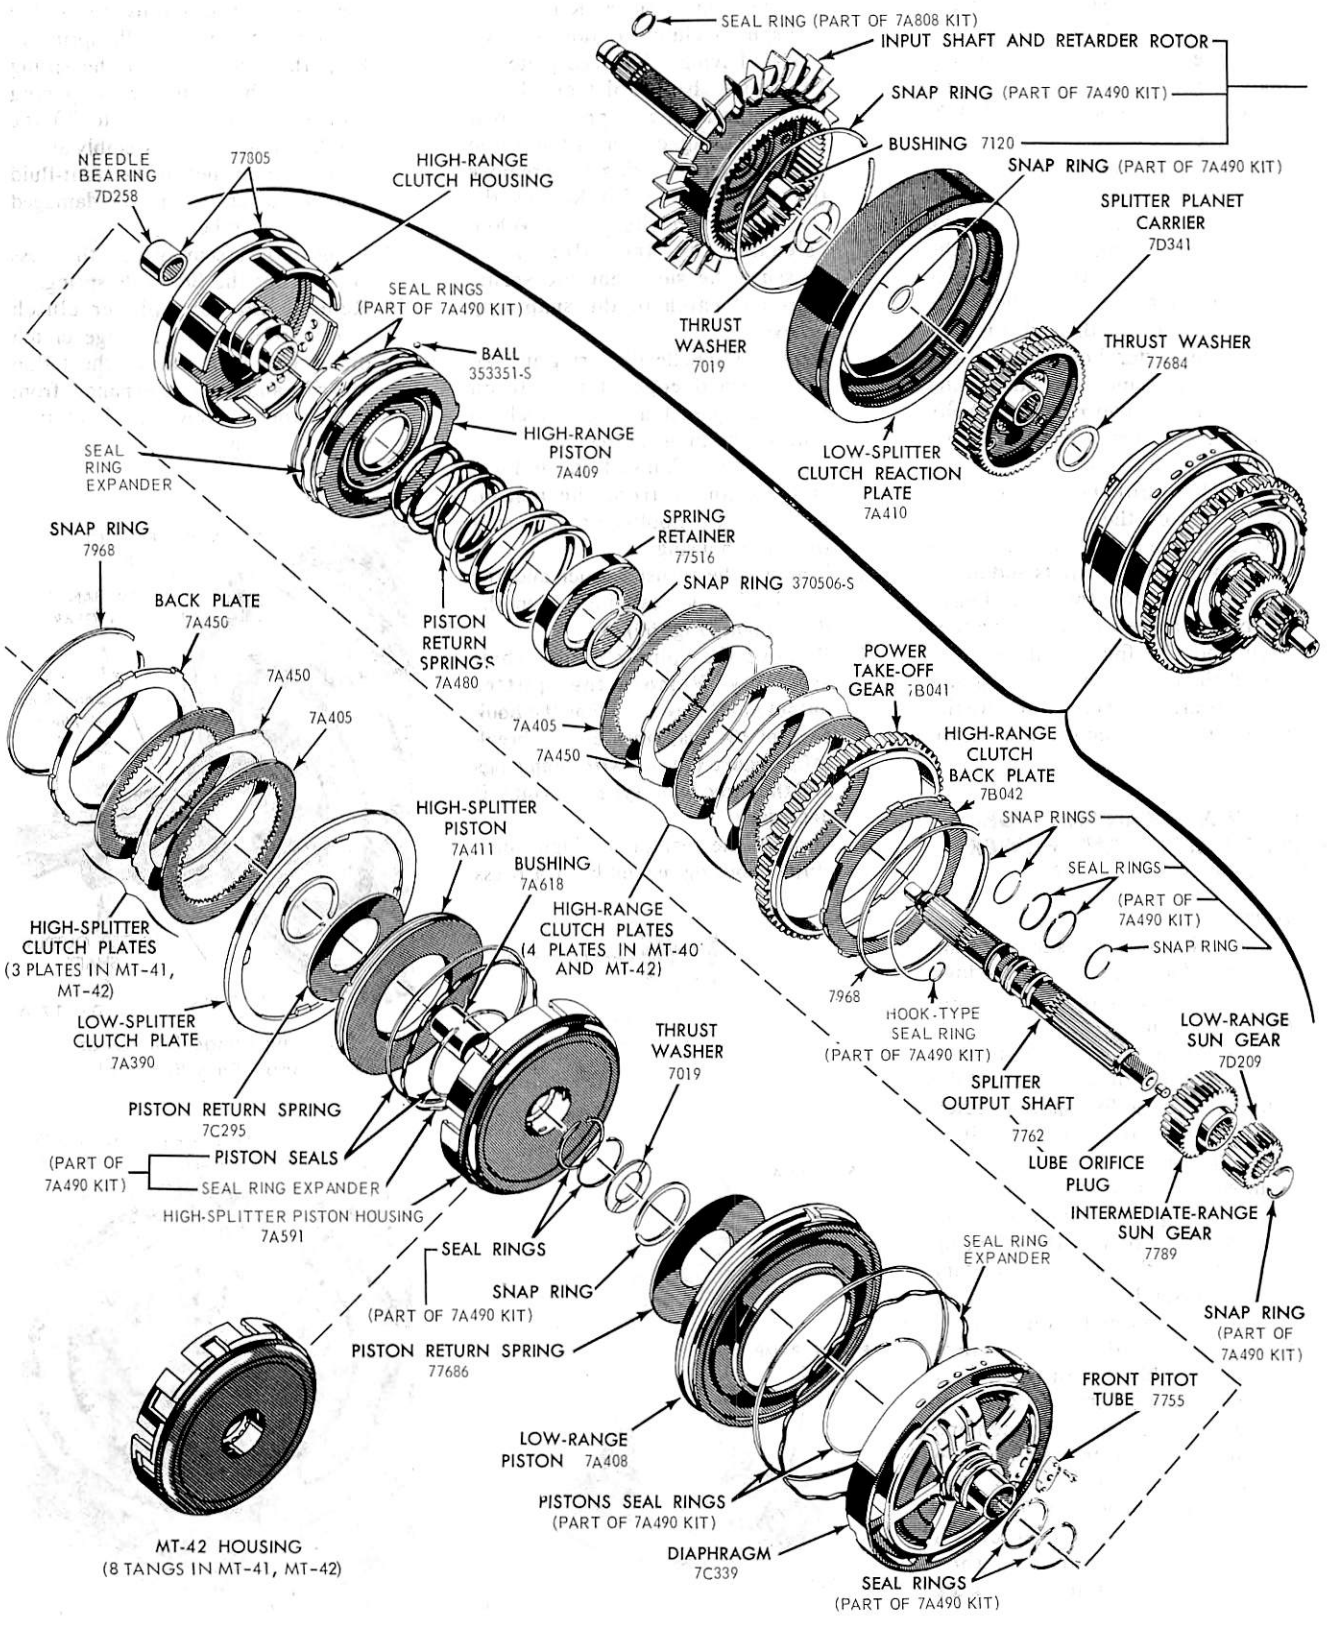

FIG. 58 Splitter Mechanism, High-Range Clutch and Power Take-Off Drive Gear

not attempt to remove the diaphragm from the assembly.

16. Remove the two front pitot tube mounting screws and lock washers from the front surface of the diaphragm to allow the pitot tube to drop into the front governor collector ring (Fig. 62). Lift the diaphragm from the assembly and remove the two hook-type seal rings from the rear of the diaphragm. Remove the pitot tube from the collector ring.
17. Support the front surface of the high-range clutch housing assembly in a press using a suitable block in the center of the housing so that the governor collector ring will not be damaged. Compress the piston return spring retainer with the tool, and remove the snap ring. Release the pressure on the piston return spring retainer slowly, making sure the inner edge of the spring retainer does not catch in the snap ring groove as the spring expands.
18. Remove the assembly from the press and lift off the retainer and springs.
19. Remove the large internal snap ring from the high-range clutch housing.
20. Remove the high-range clutch reaction plate. In 5-plate clutch assemblies, remove three internal-splined plates and two external-splined plates. In 7-plate clutch assemblies, remove four internal-splined plates and three external-splined plates. Remove the power take-off gear on models which use a separate gear.
21. Tap the rear of the housing on a wood block to loosen the high-range clutch piston. Remove the piston. Then remove the teflon seal ring and seal ring expander from the piston and the hook-type seal ring from the housing.

The high-range clutch housing needle bearing or bushing can be replaced. Refer to Removal and Installation for bushing and bearing replacement tools.

Assembly

1. Install the hook-type seal ring on the high-range clutch housing assembly. Install the teflon seal ring and the seal ring expander on the high range clutch piston assembly. Coat the seals lightly with oil.
2. Install the piston in the housing, being careful not to damage the seal rings.
3. Support the front surface of the piston housing in a press, using a suitable block at the center of the housing so that the governor collector ring will not be damaged.
4. Position the coil-type piston return springs on the top of the piston, set the retainer on the springs and position the tool on the retainer (Fig. 63). Align the hole in the retainer with the hub of the housing, and then center the tool on the retainer. Compress the springs until the retainer is sufficiently below the snap ring groove and install the snap

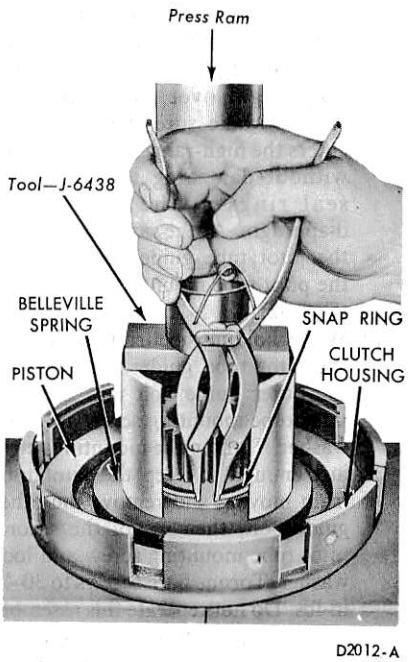

FIG. 59 High-Splitter Piston Belleville Spring Snap Ring Removal or Installation

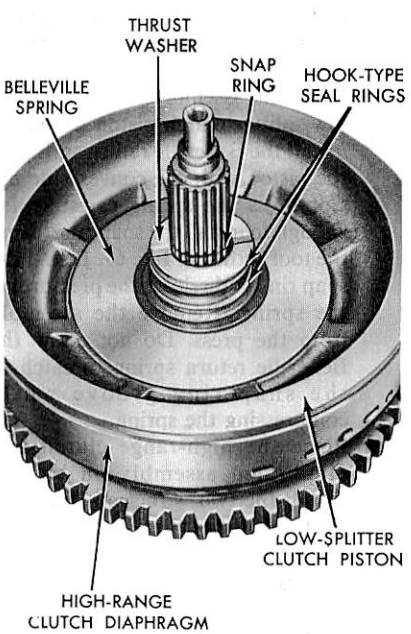

FIG. 60 Low Splitter Clutch Piston

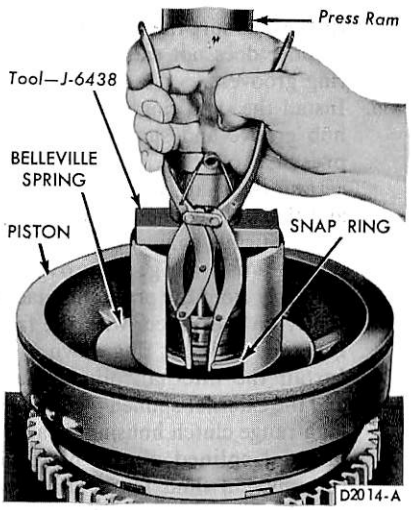

FIG. 61 Low-Splitter Piston Belleville Spring

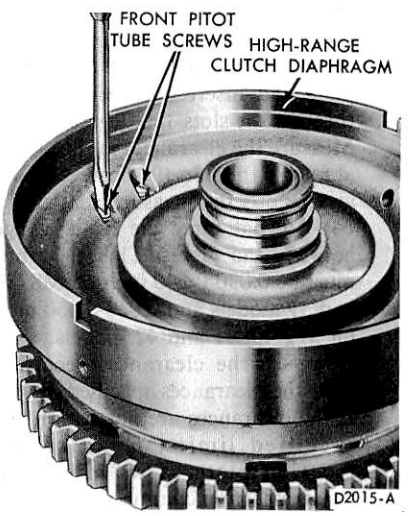

FIG. 62 Front Pitot Tube Screw Removal and Installation

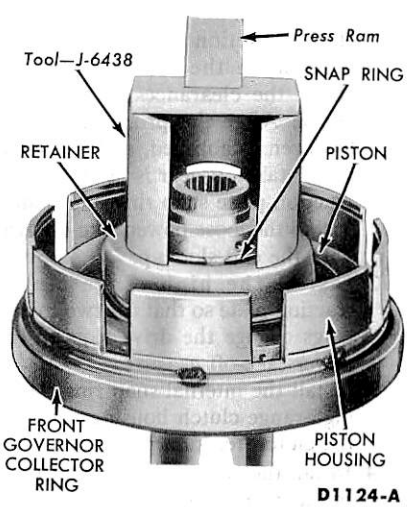

FIG. 63 High-Range Clutch Piston Return Spring Retainer Installation

ring. Make sure the inner edge of the retainer does not catch in the snap ring groove.

5. Install the snap ring in the housing hub groove and slowly release the pressure on the retainer. Make certain the snap ring is fully seated and that the retainer is straight and returns firmly against the lower side of the snap ring. Remove the assembly from the press and place it gently on the bench, with the front governor collector ring down.
6. Install the internal-splined plates and the external-splined plates in the high-range clutch housing. Soak the internal splined clutch plates in transmission fluid for at least two minutes before installation.
7. If a loose power take-off gear is used, temporarily install the high-range clutch reaction plate and snap ring without the gear.
8. Using a small screwdriver, separate the reaction plate from the clutch plate and insert two feeler gauges through the slots 180 degrees apart. Measure the clearances in the clutch at four of the slots (90 degrees apart) and record the measurements (Fig. 64). **Do not force the feeler gauge between the plates.** This clearance must be 0.030-0.040 inch on MT-30 and 31 models and 0.040-0.050 inch on MT-40, 41 and 42 models.
9. Compare the clearances recorded with the clearances specified above. If the clearances are not within the specified limits, measure the reaction plate at its maximum thickness (from contour to flat side). Select a new plate with the thickness range required. The reaction plate is available in thickness of: 0.296-0.298, 0.304-0.306, 0.312-0.314 and 0.320-0.322.
10. If the reaction plate is replaced, reassemble the clutch pack and check the clearances as described above. After the proper clearnace has been established, and if a loose power take-off gear is used, remove reaction plate snap ring and plate.
11. Install the loose power take-off gear with the end slots up.
12. Install the high-range clutch reaction plate so that the two longer tangs engage the drive slots in the power take-off gear.
13. Install the internal-snap ring in the high-range clutch housing to retain the clutch reaction plate.
14. Install the two hook-type seal rings on the rear of the high-range clutch diaphragm.
15. Install the high-range clutch with the front governor collector ring facing upward. Install the two guide bolts in the front pitot tube on the side of the pitot tube that the drilled port is located (Fig. 65). **The guide bolts can be made from two 5-inch lengths of 3/16-inch diameter brazing rod threaded with a 10-32 die a distance of 3/8-inch. Round off the unthreaded ends of the guide bolts.**
16. Place the pitot tube in the governor collector ring with the intake port toward the outer diameter of the ring. Install the high-range clutch diaphragm over the high-range clutch. Make sure the diaphragm enters the high-range clutch housing without damaging the hook-type seal rings at the rear of the diaphragm. At the same time, direct the pitot tube guide bolts through the pitot tube mounting screw holes (Fig. 62).
17. While holding up firmly on one of the pitot tube guide bolts, remove the other guide bolt and install a pitot tube mounting screw and lock washer. Tighten the mounting screw just enough to keep the pitot tube from moving and remove the other guide bolt, then install the second pitot tube mounting screw and lock washer. Torque both screws to 30-48 in-lbs. Do not separate this assembly while the pitot tube is in position.
18. Install the teflon seal ring and seal ring expander on the low-splitter clutch piston. Install the hook-type seal ring on the low-splitter piston housing side of the diaphragm.
19. Lightly coat the seal rings with oil and carefully install the low-splitter piston so that the seal rings are not damaged.
20. Place the assembly in a press with low-splitter clutch piston up, then install the Belleville return spring on the piston with the convex side up. Compress the spring carefully far enough to install the snap ring, using the tool shown in Fig. 61. Install the snap ring and release the pressure on the spring. Remove the assembly from the press. Do not allow the Belleville return spring to catch in the snap ring groove while compressing the spring.
21. Place the high-range clutch and diaphragm assembly on blocks. Install the two wire snap rings and the three hook-type seal rings on the splitter output shaft assembly. Lightly coat the seal rings with oil and carefully install the splitter shaft so that the seal rings are not damaged.
22. Install the hook-type seal ring on the inner diameter of the high-splitter clutch housing and gear.
23. Install a teflon seal ring and a seal ring expander on the outer diameter of the high-splitter piston.
24. Lightly coat the seals with transmission fluid and install the piston in the housing, being careful not to damage the seals.
25. Place the piston and housing assembly in a press with the piston up, then install the Belleville piston return spring on the piston with the convex side up. Compress the spring carefully and only far enough to

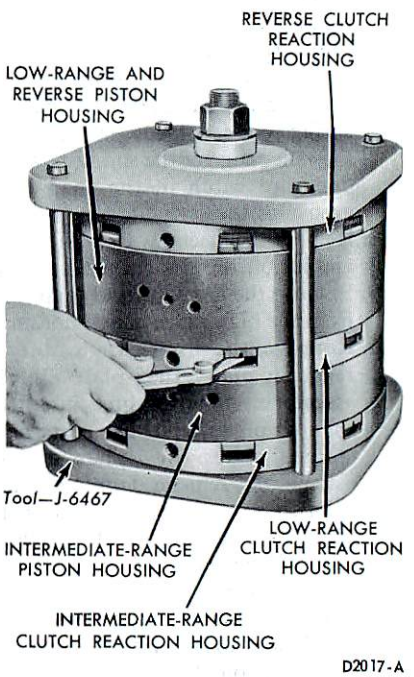

FIG. 64 Range Clutch Clearance Check

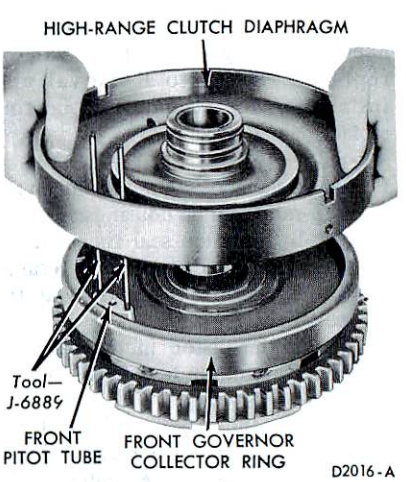

FIG. 65 High-Range Clutch Diaphragm Installation

install the snap ring, using the tool shown in Fig. 59. Install the snap ring and release the pressure on the spring. Remove the assembly from the press.

26. On models using a six tang plate, install the low-splitter clutch friction plate on the highsplitter clutch housing so that the six internal tangs do not engage the slots in the housing where the high-splitter piston tangs are located (Fig. 66). If the tangs are installed in the same slots, in error, both splitter clutches will be applied when the high-splitter piston is actuated.
27. Install the internal and external-splined plates.
28. Install the high-splitter clutch back plate. Install the large internal snap ring which retains the back plate.
29. Install the two hook-type seal rings and the bronze thrust washer on the front side of the diaphragm, then apply a light coat of oil to these parts.
30. On models using an 8-tanged low-splitter clutch plate, install the plate on the assembled high-splitter clutch engaging the eight slots on the outside of the housing. The six tanged plate is installed at the time of the high-splitter clutch assembly, being careful not to damage the ring seals.
31. Coat the bronze thrust washer with oil-soluble grease and install the washer in the splitter planetary carrier assembly.
32. Install the splitter planetary carrier assembly, splining it on the splitter output shaft and meshing the external teeth with those of the splitter clutch plates. Install the snap ring on the splitter shaft to retain the splitter planetary carrier assembly.
33. Lightly coat the bronze thrust washer with oil and install the washer on the splitter planetary carrier.
34. Remove the splitter assembly from the blocks and place it on its side. **Be careful in handling the assembly until the low-and intermediate-range sun gears are installed and retained by snap rings so that the front pitot tube will not damage the front governor collector ring.**
35. Install the intermediate-and low-range sun gear with the chamfered end of teeth outward (Fig. 58).
36. While holding the splitter shaft by the opposite end, install the snap ring to retain the sun gears.

REVERSE RANGE CLUTCH PLATE AND RING GEAR (MT-30 AND MT-31 MODELS)

Disassembly

1. Straighten the clutch plate retainer ring at either side of the plate, and remove the ring.
2. Lift the plate off the gear. Then straighten and remove the other ring.

Assembly

1. Engage the internal splines of the clutch plate with the external splines of the ring gear, and position the plate between the two grooves cut around the outside diameter of the ring gear.
2. Place a new clutch plate retainer ring in one of the two grooves and crimp the ring at five evenly spaced intervals around the gear. Be sure that the ring is installed well below the clutch plate surface. **Do not crimp the retainer ring at points where cutouts are made in the friction facings.**
3. Turn the assembly over and install a second new retainer ring in the same manner as the first ring.

LOW-RANGE AND REVERSE PISTON HOUSING OR INTERMEDIATE-RANGE PISTON HOUSING

Disassembly

1. Tap the edge of the housing on a wood block to loosen the pistons, then remove the pistons from the housings.
2. Remove the seal ring and seal ring expander from the outer groove of the piston, and the hook-type seal ring from the housing, or from the piston in the case of the intermediate-range piston.

To remove the teflon seals, loosely tie a piece of heavy cord around the seal. Then, twist a screwdriver into the cord and work the cord around the seal until the seal bulges out from the piston enough to insert a screwdriver under the seal. Remove the seal and expander from the piston.

Discarded teflon seals should not be disposed of by burning unless adequate ventilation is provided as certain harmful gasses are given off when seals are subjected to high temperatures.

Assembly

1. Install a new seal and expander in the outer groove of the piston, and a hook-type seal ring on the housing, or on the piston, in the case of the intermediate-range piston. Install the expander in the seal ring groove with the ends pointing toward the bottom of the groove. Retain the expander in the groove by hand and begin the installation of the seal into the groove at a point opposite the ends of the expander. Continue until the seal is fully seated. The use of tools is not recommended.
2. Lightly coat the seals with oil and install the piston, pushing them all the way into the housings. **Be careful not to damage the seals.**

LOW-RANGE RING GEAR AND INTERMEDIATE-RANGE PLANETARY CARRIER

Disassembly

1. Remove the internal-snap ring from the low-range ring gear, using a sharp pointed drift pin.
2. Lift out the intermediate-range planetary carrier.

Assembly

1. Mesh the external teeth of the planetary carrier with the internal teeth of the ring gear and push the carrier into the ring gear.
2. Install the internal-snap ring to hold the assembly together.

PROCEDURE FOR CHECKING RANGE CLUTCH CLEARANCES PRIOR TO TRANSMISSION ASSEMBLY

Check the clutch clearances if any pistons, piston housing, apply plates, reaction housings, Belleville springs, or clutch plates have been replaced in the low-range, intermediate-range or reverse clutches. Perform this check before assembling these clutches in the transmission housing, using the tool shown in Fig. 64. These clutches should be checked on every rebuild or

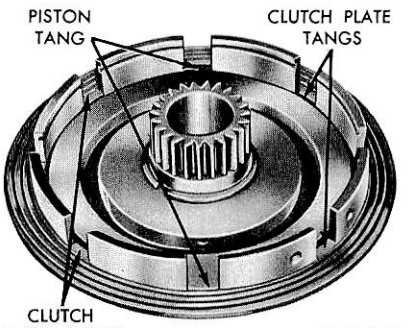

FIG. 66 Low-Splitter Clutch Plate Installation

disassembly to be certain they meet the proper clearance specifications of:

Low-Range
(3-plate)-0.020 to 0.030
(Single Plate)-0.010 to 0.015
Intermediate-Range
0.030 to 0.040
High-Range
(5-Plate)-0.030 to 0.040
(7-Plate)-0.040 to 0.050
Reverse-Range
(3-Plate)-0.020 to 0.030
(Single Plate)-0.010 to 0.015

Assembly of Clutches in Tool

1. Place the intermediate-range clutch reaction housing (yellow marked) in the tool with four of the slots adjacent to the four posts of the tool (Fig. 64).
2. Place an intermediate-range internally splined clutch plate in the intermediate-range reaction housing. Position the externally splined plate and the other internally splined plate. Install the intermediate-range clutch apply plate, the intermediate-range clutch Belleville spring with the convex side up, the intermediate-range clutch piston and the piston housing with the piston down.
3. Install the low-range clutch reaction housing with the slots up, the low-range clutch plate(s) and the low-range clutch apply plate with the flat side down.
4. Install the low-range Belleville spring with the convex side up, and then install the low-range and reverse piston and housing assembly with the red marking up (long piston hub down).
5. Install the reverse Belleville spring with the convex side down, and install the reverse clutch apply plate with the flat side up.
6. Install the reverse clutch plate(s), and then install the reverse clutch reaction housing with the slots down.
7. Place the top plate of the tool on the clutch stack, then install the tool bearing, flat washer, and the nut.
8. Use a 1 5/8-inch socket wrench to torque the nut to 30 ft-lbs. Make certain that all clutch parts are perfectly centered. Torque must cause metal-to-metal contact at outside diameters of piston housing and clutch plate reaction housings to insure accurate measurement of clutch clearance.

Checking Clutch Clearance

1. Use a small screwdriver to separate the plates, and then measure the clearances between the clutch friction plates and the clutch apply plates of the reverse clutch with a feeler gauge. This clearance should be 0.010-0.015 inch for single plate and 0.020-0.030 inch for three plate (Fig. 59).
2. Repeat this operation for the low-range clutch. The low-range clutch clearance should be 0.010-0.015 inch for single plate and 0.020-0.030 inch for three plate.
3. Check the intermediate-range clutch in the same way. The clearance should be 0.030-0.040 inch.
4. If the clutches do not have the specified clearances, it will be necessary to replace the apply plates. The apply plates are available for reverse, and low-ranges in nine thicknesses: 0.458-0.462, 0.465-0.469, 0.472-0.476, 0.312-0.316, 0.298-0.302, 0.284-0.288, 0.270-0.274, 0.291-0.295, and 0.277-0.281 inch. The intermediate-range apply plates are available in six thicknesses: 0.312-0.316, 0.302-0.298, 0.288-0.284, 0.270-0.274, 0.291-0.295 and 0.277-0.281 inch.
5. Measure the maximum thickness of the apply plate from the clutch stack and, by considering the clearance measurement taken while the stack is assembled, choose the correct plate to bring the clearance to specifications.
6. Establish the correct clutch clearance for the three ranges, then remove the clutch pack from the fixture and stack them on a bench in the reverse order. Now, each part may be selected in the correct order for assembly in the transmission housing.

FOREWORD

This manual is divided into five volumes: 1 – Chassis, 2 – Engine, 3 – and 4 – Electrical and Body, 5 – Maintenance and Lubrication. These volumes should provide Service Technicians with complete information covering normal service repairs on all 1973 model trucks built by the Ford Companies in the U. S. and Canada. As changes in the product occur, this information will be updated by Technical Service Bulletins. When issued, T.S.B. information always supersedes the information in the manual.

Information in each volume is grouped by system or component plus "General Service" part which contains information common to several similar components.

The table of contents on the first page of each volume indicates the general content of the book and provides a handy tab locator to make it easy to find the first page of each "Group." That page will contain an index to "Parts" and the first page of each "Part" contains a detailed index which gives page location for each service operation covered. Page numbers are consecutive in each "Part."

To make reference easier, information has been broken down into smaller units so that essentially there is now one "Part" for each component or system. Group numbers indicate the volume in which the group may be found.

Example: 11 – 02 – 21

Volume 1 – Group 11 – Part 02 – Page 21

The descriptions and specifications in this manual were in effect at the time this manual was approved for printing. Ford Marketing Corporation reserves the right to discontinue models at any time, or change specifications or design, without notice and without incurring obligation.

Vehicle Identification

GROUP 20

GENERAL INFORMATION

VEHICLE CERTIFICATION LABEL

The Vehicle Certification Label (V.C. Label) is attached to the rear face of the driver's door. The upper half of the label contains the name of the manufacturer, the month and year of manufacture and the certification statement. The V.C. Label also contains the Vehicle Identification Number.

The remaining information codes on the V.C. Label are the same as the Truck Rating Plate Codes (Fig. 1). Vehicle codes shown on the Truck Rating Plate are explained in the following paragraphs.

RATING PLATE

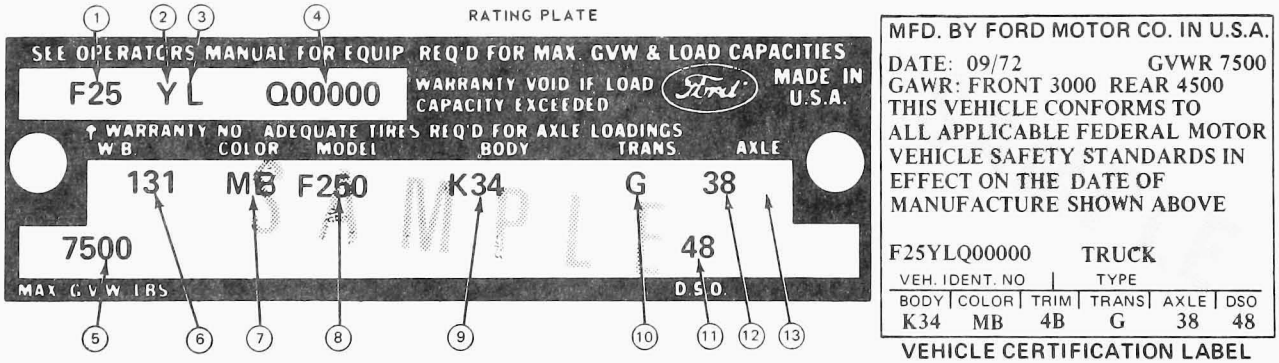
Figure 1 illustrates a typical Truck Rating Plate. On light and medium cowl and windshield vehicles, the Rating Plate is mounted on the right side of the cowl top panel under the hood. On stripped Parcel Delivery vehicles, the rating plate is placed in an envelope and included in the Boxed Items parts. On Bronco models, the plate is mounted on the inside panel of the glove compartment door. On all other vehicles, the Rating Plate is mounted on the rear face of the left front door.

VEHICLE IDENTIFICATION NUMBER

The identification number is the first line of numbers and letters appearing on the Rating Plate (Fig. 1). The first letter and two numbers indicate the truck model and series (the letter prefix identifies the type of body or cab and the numbers are the first two numbers of a truck series). The letter following the truck series code designates the engine identification code. The letter following the engine identification code indicates the assembly plant at which the vehicle was built. The remaining numbers indicate the consecutive unit number. The charts that follow list the various vehicle identification number codes.

VEHICLE DATA

The Vehicle Data appears on the Rating Plate on the two lines following the identification number. The first three digits under W.B. designate the wheelbase in inches. The one or two letters under COLOR identify the exterior paint color (two letters designate a two-tone). The letter and three digits under MODEL designate the truck model within a series. The letter and numerals under BODY designate the interior trim and body type (the letter identifies the interior trim scheme and the numerals identify the body or cab type). The transmission installed in the vehicle is identified under TRANS by either a numeric or alphabetical code (if two symbols appear, the first identifies the auxiliary transmission, if so equipped, and the second symbol identifies the main transmission). A letter and a number or two numbers under AXLE identify the rear axle ratio (when required, a letter is



W1017-F

FIG. 1 Typical Truck Rating Plate and Vehicle Certification Label

also stamped behind the rear axle code to identify the front axle capacity). The maximum gross vehicle weight in pounds is stamped under MAX. G.V.W.

A two-digit number is stamped under D.S.O. to identify the district which ordered the vehicle. If the vehicle is built to special order (Domestic Special Order, Foreign Special Order, Limited Production Option, or other special order), the complete order number will also appear under D.S.O. The charts that follow list the various vehicle data codes.

W.B. (WHEELBASE)

The wheelbase in inches is entered in this space.

MAX. G.V.W. LBS

The maximum gross vehicle weight in pounds is recorded in this space.

D.S.O.

If vehicle is built on a **D.S.O., F.S.O., L.P.O.** (special orders) the complete order number will be reflected under the D.S.O. space including the District Code Number.

GENERAL INFORMATION

This part covers engine tests adjustment and repair procedures. In addition, the cleaning and inspection procedures are covered.

For engine removal, disassembly, assembly installation and major repair procedures, refer to the applicable engine part.

An engine identification tag is attached to the engine. The symbol code (Fig. 1) identifies each engine for determining parts usage; i.e., engine cubic inch displacement and model year. The change level and engine code number determine if parts are peculiar to a specific engine. The engine plant code designates where and when the engine was built. **It is imperative that the codes on the engine identification tag be used when ordering parts or making inquiries about the engine. The pertinent codes are shown in the Master Parts Catalog to designate unique parts.**

The 1973 engines incorporate Imco exhaust emission control system or a nonexhaust emission control system.

The Imco system is designed to reduce the hydrocarbon and carbon monoxide content of the gasoline engine exhaust gases. By controlling the amount of contaminants emitted through the exhaust system to an acceptable minimum, air polution is reduced.

When making carburetor idle fuel mixture and speed adjustments, follow the procedures in Group 24.

The Imco exhaust emission control system uses a specially-calibrated carburetor and distributor in conjunction with retarded ignition timing at idle speeds. This reduces the exhaust contaminants by burning them within the cylinder combustion chamber before reaching the exhaust manifold.

FIG. 1 Engine Identification

DIAGNOSIS AND TESTING

Refer to the Truck Diagnosis Manual for all diagnosis procedures.

CAMSHAFT LOBE LIFT

Check the lift of each lobe in consecutive order and make a note of the readings.

1. Remove the air cleaner. Remove the heater hose and crankcase ventilation hose. Remove valve rocker arm cover(s).
2. Super Duty Engines with mechanical valve lifters: if only one camshaft lobe is to be checked, loosen the valve rocker arm adjusting screw. Slide the rocker arm assembly serving the camshaft lobe to be checked to one side. Secure it in this position. To move the rocker arm on either end of the shaft, remove the retaining pin and washers, and slide the rocker arm off the shaft. Repeat this procedure on other lobes to be checked. Never remove the rocker arm pedestal attaching bolts and rocker arm shaft to check camshaft lobe lift on the Super Duty Engines. **Removing the rocker arm attaching bolts will cause torque loss of the cylinder head and will necessitate cylinder head gasket replacement.**

On 330, 360, 361, 390 and 391 CID engines with hydraulic valve lifters, remove the valve rocker arm shaft assembly(ies) and install a solid, tappet-type push rod in the push rod bore of the camshaft lobe to be checked or use the adapter for ball end push rods shown in Fig. 2.

On a 240 or 300 Six, remove the rocker arm stud nut, fulcrum seat and rocker arm. Use the adapter for ball end push rods.

3. Make sure the push rod is in the valve lifter socket. Install a dial indicator so that the actuating point of the indicator is in the push rod socket (or the indicator ball socket adapter is on the end of the push rod) and in the same plane as the push rod movement (Fig. 3 or 4).
4. Disconnect the brown lead (I terminal) and the red and blue lead (S terminal) at the starter relay. Install an auxiliary starter switch between the battery and S terminals of the starter relay. Crank the engine with the ignition switch OFF.

Turn the crankshaft over until the tappet or lifter is on the base circle of the camshaft lobe. At this point, the push rod will be in its lowest position.

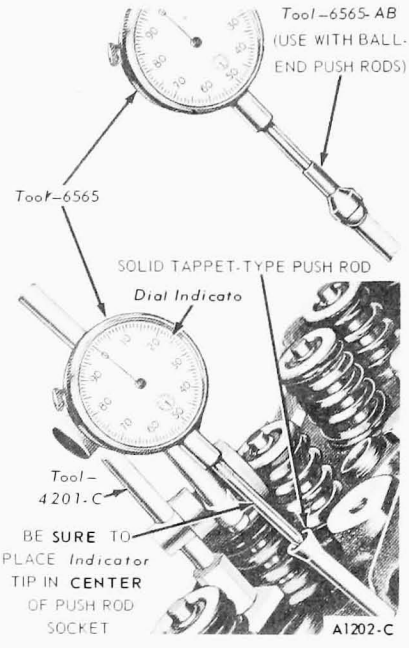

FIG. 2 Typical Camshaft Lobe Lift Hydraulic Valve Lifters—V-8 Engines

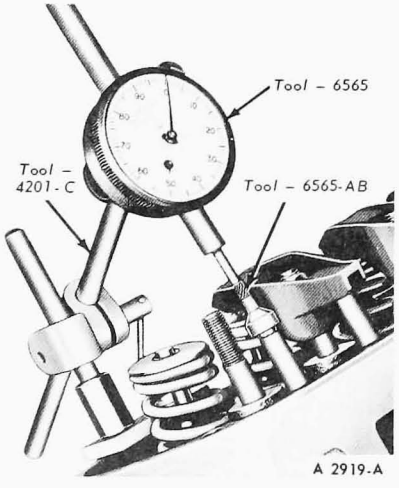

FIG. 3 Typical Camshaft Lobe Lift—240 and 300 Six Engines

5. Zero the dial indicator. Continue to rotate the crankshaft slowly until the push rod is in the fully raised position.
6. Compare the total lift recorded on the indicator with specification.
7. To check the accuracy of the original indicator reading, continue to rotate the crankshaft until the indicator reads zero. If the lift on any lobe is below specified wear limits, the camshaft and the valve lifters operating on the worn lobe(s) must be replaced.
8. Remove the dial indicator and auxiliary starter switch.

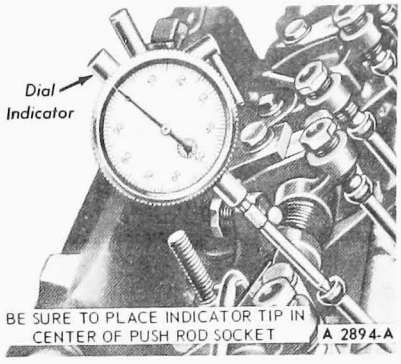

FIG. 4 Typical Camshaft Lobe Lift—Mechanical Tappets

On Super Duty Engines, position the valve rocker arm. If an end valve rocker arm was removed, slide it into position on the shaft, and install the washers and retaining pin. Tighten the valve clearance adjusting screw to hold the rocker arm and push rod in alignment. Adjust the valve clearance on all rocker arms that had been moved out of position. Install the valve rocker arm cover(s) and partially tighten the attaching bolts. Operate the engine until normal operating temperature has been reached. Remove the valve rocker arm cover(s). Check and adjust the valve clearance.

On 330, 360, 361, 390 and 391 CID engines install the valve rocker arm shaft assembly(ies).

On a 240 or 300 Six, install the rocker arm, fulcrum seat and stud nut. Adjust the valve clearance

9. Install the valve rocker arm cover(s) and the air cleaner.

COMPRESSION TEST

The following procedure is to be used on all engines when checking compression:

1. Be sure the crankcase oil is of the correct viscosity and make sure that the battery is properly charged. Operate the engine for a minimum of 30 minutes at 1200 rpm, or until the engine is at normal operating temperature. Turn the ignition switch off; then remove all the spark plugs.

2. Set the carburetor throttle plates in the wide open position.
3. Install a compression gauge in No. 1 cylinder.
4. Crank the engine (with the ignition switch off) at least five (5) pumping strokes and record the highest reading indicated. Note the approximate number of compression strokes required to obtain the highest reading.
5. Repeat the check on each cylinder cranking the engine approximately the same number of compression strokes.

The indicated compression pressures are considered normal if the lowest reading cylinder is within 75 percent of the highest. Refer to the quick reference chart Fig. 5 for pressure limits between cylinders. Variations exceeding 75 percent implies an improperly seated valve or worn or broken piston rings. If one, or more, cylinders read low-squirt approximately one (1) tablespoon of engine oil on top of the pistons in the low reading cylinders. Repeat compression pressure check on these cylinders.

a. If compression improves considerably, the piston rings are at fault.
b. If compression does not improve, valves are sticking or seating poorly.
c. If two adjacent cylinders indicate low compression pressures and squirting oil on the pistons does not increase the compression, the cause may be a cylinder head gasket leak between the cylinders. Engine oil and/or coolant in the cylinders could result from this problem.

EXAMPLE

After checking the compression pressures in all cylinders, the highest reading obtained was 140 psi and the lowest pressure reading was 100 psi. By locating 140 in the Maximum column it is seen that the lowest allowable pressure listed in the Minimum column is 105 psi. Since the lowest cylinder reading was 100 psi, the engine is within specifications and the compression is considered satisfactory.

Maximum PSI	Minimum PSI	Maximum PSI	Minimum PSI
134	101	194	145
136	102	196	147

CA1340-A

FIG. 5 Quick Reference Compression Pressure Limit Chart

HYDRAULIC VALVE LIFTER

Dirt, deposits of gum and varnish and air bubbles in the lubricating oil can cause hydraulic valve lifter failure or malfunction.

Dirt, gum and varnish can keep a check valve from seating and cause a loss of hydraulic pressure. An open valve disc will cause the plunger to force oil back into the valve lifter reservoir during the time the push rod is being lifted to force the valve from its seat.

Air bubbles in the lubricating system can be caused by too much oil in the system or too low an oil level. Air may also be drawn into the lubricating system through an opening in a damaged oil pick-up tube. Air in the hydraulic system can cause a loss of hydraulic pressure.

Assembled valve lifters can be tested with Tool 6500-E to check the leak down rate. The leak down rate specification is the time in seconds for the plunger to move the length of its travel while under a 50 lb load. Test the valve lifters as follows:

1. Disassemble and clean the lifter to remove all traces of engine oil. Lifters cannot be checked with engine oil in them. Only the testing fluid can be used.
2. Place the valve lifter in the tester, with the plunger facing upward. Pour hydraulic tester fluid into the cup to a level that will cover the valve lifter assembly. The fluid can be purchased from the manufacturer of the tester. Do not use kerosene, for it will not provide an accurate test.

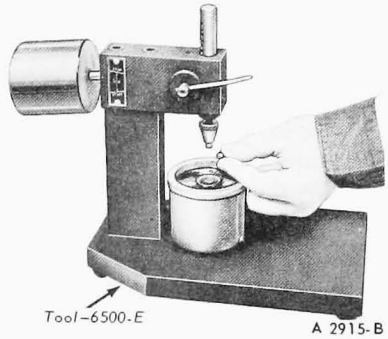

FIG. 6 Placing Steel Ball in Valve Lifter Plunger

3. Place a 5/16 inch steel ball in the plunger cup (Fig. 6).
4. Adjust the length of the ram so that the pointer is 1/16 inch below the starting mark when the ram contacts the valve lifter plunger (Fig. 7) to facilitate timing as the pointer passes the start timing mark.

Use the center mark on the pointer scale as the stop timing point instead of the original stop timing mark at the top of the scale.

5. Work the valve lifter plunger up and down until the lifter fills with fluid and all traces of air bubbles have disappeared.
6. Allow the ram and weight to force the valve lifter plunger downward. Measure the exact time it takes for the pointer to travel from the start timing to the stop timing marks on the tester.
7. A valve lifter that is satisfactory must have a leak-down rate (time in seconds) within the minimum and maximum limits specified.
8. If the valve lifter is not within specifications, replace it with a new lifter. It is not necessary to test a new lifter before installing it in the engine.

CRANKCASE VENTILATION SYSTEM OPERATION TEST

This test is performed with the crankcase ventilation tester, C8AZ6B627-A (Fig. 8) which is operated by the engine vacuum through the oil fill opening. Follow the procedures described below to install the tester and check the crankcase ventilation system for faulty operation.

1. With the engine at normal operating temperature, remove the oil filler cap.
2. Hold the tester C8AZ6B627-A over the opening in the valve cover. Make sure the surface is flat to form a seal between the cover and tester. If the cover is distorted, shape it as required to make an air tight seal. An air leak between the cover and tester will render the tester inoperative or give an erroneous reading.
3. Start the engine and allow it to operate at the recommended idle speed.
4. Hold the tester over the oil filler cap opening making sure that there is a positive seal between the tester and cover.
5. If the ball settles in the Good (green) area, the system is functioning properly. If the ball settles in the Repair (red) area, clean or replace the malfunctioning components as required.
6. Repeat the test after repairs are made to make sure that the crankcase ventilation system is operating satisfactorily.

Regulator Valve Test

Install a known good regulator valve in the crankcase ventilation system.

Start the engine and compare the engine idle condition to the prior idle condition.

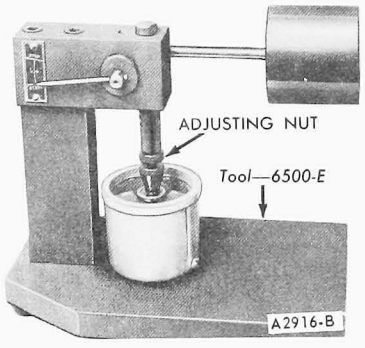

FIG. 7 Adjusting Ram Length

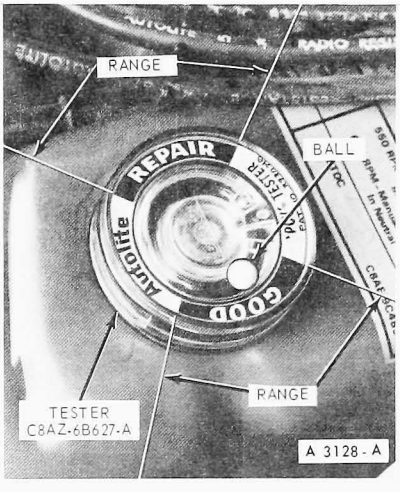

FIG. 8 Crankcase Ventilation System Tester

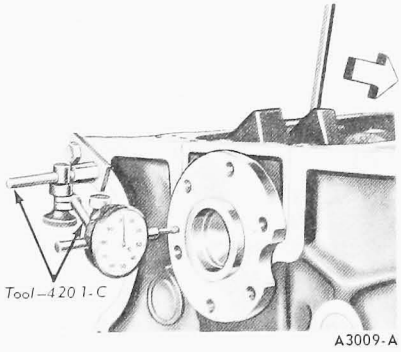

FIG. 9 Checking Crankshaft End Play

If the loping or rough idle condition remains when the good regulator valve is installed, the crankcase ventilation regulator valve is not at fault. Check the crankcase ventilation system for restriction at the intake manifold or carburetor spacer. If the system is not restricted, further engine component diagnosis will have to be conducted to find the malfunction.

If the idle condition is found to be satisfactory, leave the new regulator valve installed and clean the hoses, fittings, etc.

CRANKSHAFT END PLAY

1. Force the crankshaft toward the rear of the engine.
2. Install a dial indicator so that the contact point rests against the crankshaft flange and the indicator axis is parallel to the crankshaft axis (Fig. 9).
3. Zero the dial indicator. Push the crankshaft forward and note the reading on the dial.
4. If the end play exceeds the wear limit, replace the thrust bearing. If the end play is less than the minimum limit, inspect the thrust bearing faces for scratches, burrs, nicks, or dirt. If the thrust faces are not damaged or dirty, they probably were not aligned properly. Install the thrust bearing and align the faces following the procedure recommended under Main Bearing Replacement in the pertinent engine section. Check the crankshaft end play.

FLYWHEEL FACE RUNOUT—MANUAL-SHIFT TRANSMISSION

Install a dial indicator so that the indicator point bears against the flywheel face (Fig. 10). Turn the flywheel making sure that it is full forward or rearward so that crankshaft end play will not be indicated as flywheel runout.

If the clutch face runout exceeds specifications, remove the flywheel and check for burrs between the flywheel and the face of the crankshaft mounting flange. If no burrs exist, check the runout of the crankshaft mounting flange. Replace the flywheel or machine the crankshaft-flywheel mounting face if the mounting face flange runout is excessive. If the ring gear runout exceeds specifications, replace it or reinstall it on the flywheel. Refer to Ring Gear Replacement for the proper procedure.

FLYWHEEL RUNOUT—AUTOMATIC TRANSMISSION

Remove the spark plugs.

Install a dial indicator so that the indicator point rests on the face of the ring gear adjacent to the gear teeth.

Push the flywheel and crankshaft forward or backward as far as possible to prevent crankshaft end play from being indicated as flywheel runout.

Set the indicator dial on the zero mark. Turn the flywheel one complete revolution while observing the total indicator reading (TIR). If the TIR exceeds specifications, the flywheel and ring gear assembly must be replaced.

CAMSHAFT END PLAY

On all V-8 engines, prying against the aluminum-nylon camshaft sprocket, with the valve train load on the camshaft, can break or damage the sprocket. Therefore, the rocker arm adjusting nuts must be backed off, or the rocker arm and shaft assembly must be loosened sufficiently to free the camshaft (330, 360, 361, 390 and 391 only).**Do not loosen Super Duty Engine rocker arm pedestal attaching bolts.** After checking the camshaft end play, adjust the valve clearance.

Push the camshaft toward the rear of the engine. Install a dial indicator so that the indicator point is on the camshaft sprocket attaching screw (Fig. 11). Zero the dial indicator. Position a large screwdriver between the camshaft gear and the block. Pull the camshaft forward and release it. Compare the dial indicator reading with the specifications.

If the end play is excessive, check the spacer for correct installation before it is removed. If the spacer is correctly installed, replace the thrust plate.

Remove the dial indicator.

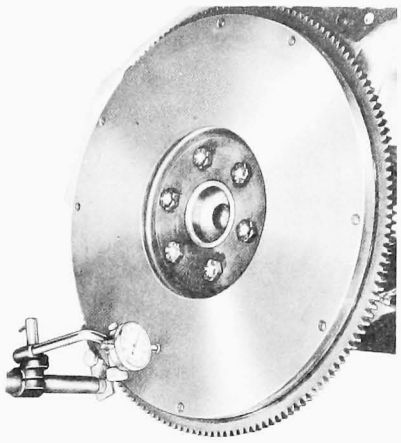
TIMING CHAIN DEFLECTION

1. Rotate the crankshaft in a counterclockwise direction (as viewed from the front) to take up the slack on the left side of the chain.
2. Establish a reference point on the block and measure from this point to the chain (Fig. 12).
3. Rotate the crankshaft in the opposite direction to take up the slack on the right of the chain. Force the left side of the chain out with the fingers and measure the distance between the reference point and the chain. The deflection is the difference between the two measurements.

If the deflection exceeds specifications, replace the timing chain and sprockets.

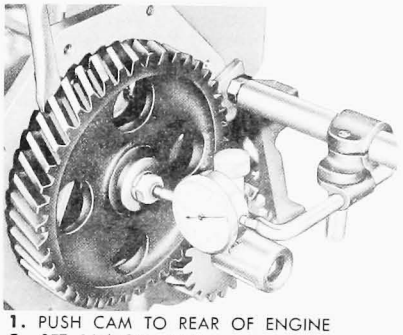
TIMING GEAR BACKLASH

Install a dial indicator on the cylinder block (Fig. 13). Check the backlash between the camshaft gear and the crankshaft gear with a dial indicator. Hold the gear firmly against the block while making the check. Refer to specifications for the backlash limits.



A3111-A

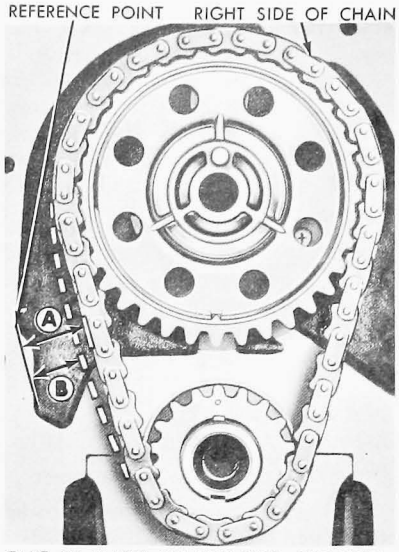
FIG. 10 Checking Flywheel Face Runout



1. PUSH CAM TO REAR OF ENGINE
2. SET *Dial* ON ZERO
3. PULL CAM FORWARD AND RELEASE

A3010-A

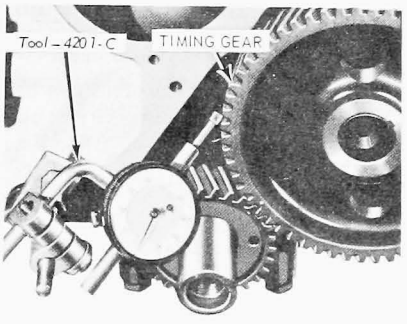
FIG. 11 Checking Camshaft End Play



TAKE UP SLACK ON LEFT SIDE, ESTABLISH REFERENCE POINT. MEASURE DISTANCE **A.** TAKE UP SLACK ON RIGHT SIDE. FORCE LEFT SIDE OUT. MEASURE DISTANCE **B.** DEFLECTION IS **A** MINUS **B.**

A 2906-A

FIG. 12 Checking Timing Chain Deflection



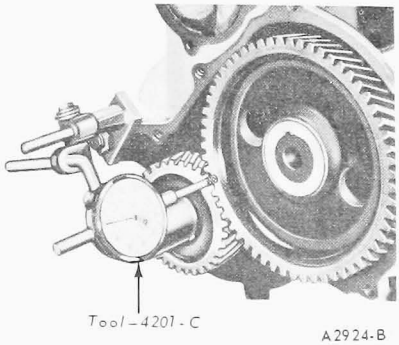
A2923-C

FIG. 13 Checking Timing Gear Backlash

TIMING GEAR RUNOUT

Install a dial indicator on the cylinder block as shown in Fig. 14. Hold the camshaft gear against the camshaft thrust plate, and zero the indicator. Rotate the crankshaft to turn the camshaft, while holding the camshaft gear against the thrust plate. Check the gear runout through one complete revolution of the camshaft. If the gear runout exceeds specifications, remove it and check for burrs or foreign particles on or between the camshaft and gear joining flanges. Check the runout. If it still exceeds specifications, replace both gears.

Follow the above procedure to check crankshaft gear runout.



A2924-B

FIG. 14 Checking Timing Gear Runout

REMOVAL AND INSTALLATION

ROCKER ARM STUD NUT REPLACEMENT—240 SIX AND 302 V-8

If the rocker arm stud nut breakaway torque is less than specified, install a new standard stud nut and recheck the breaking torque. Refer to Valve Clearance Adjustment in Part 21-04 for the torque procedure.

ROCKER ARM STUD REPLACEMENT—240 SIX, AND 302 V-8

If it is necessary to remove a rocker arm stud, Tool Kit T62F-6A527-B is available which contains the following: a stud remover, a 0.006 inch oversize reamer and a 0.015 inch oversize reamer. For 0.010 inch oversize studs, use reamer T66P-6A527-B. To press in replacement studs, use stud replacer T64P-6A527-A on a 240 or 302 engine.

Rocker arm studs that are broken or have damaged threads may be replaced with standard studs. Loose studs in the head may be replaced with 0.006, 0.010 or 0.015 inch oversize studs which are available for service.

Standard and oversize studs can be identified by measuring the stud diameter within 1 1/8 inch from the pilot end of the stud. The stud diameters are:

0.006 oversize...0.3774-0.7781
0.010 oversize...0.3814-0.3821
0.015 oversize...0.3864-0.3871

When going from a standard size rocker arm stud to a 0.010 or 0.015 inch oversize stud, always use the 0.006 inch oversize reamer before finish reaming with the 0.010 or 0.015 inch oversize reamer.

1. Position the sleeve of the rocker arm stud remover (Tool T62F-6A527-B) over the stud with the bearing end down. When working on a 302 cylinder head, cut the threaded part of the stud off with a hack saw. This is necessary due to the puller being designed for 3/8 inch studs and will not grip the 5/16 inch thread on a 302 CID cylinder head stud. Thread the puller into the sleeve and over the stud until it is fully bottomed. Hold the sleeve with a wrench, then rotate the puller clockwise to remove the stud (Fig. 15).

If the rocker arm stud was broken off flush with the stud boss, use an easy-out to remove the broken stud following the instructions of the tool manufacturer.

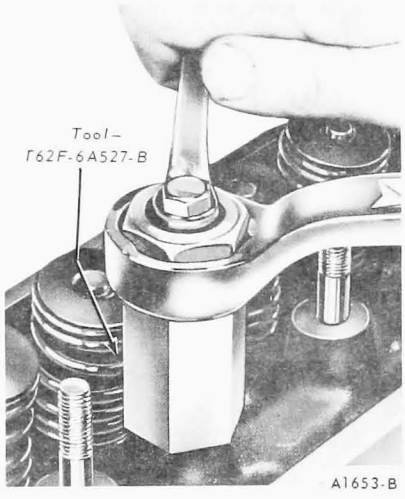


FIG. 15 Removing Rocker Arm Stud—240 Six and 302-W V-8

2. If a loose rocker arm stud is being replaced, ream the stud bore using the proper reamer (or reamers in sequence) for the selected oversize stud (Fig. 16). **Make sure the metal particles do not enter the valve area.**
3. If working on a 240 or 302 CID engine, thread the new stud into the sliding driver of the rocker arm stud installer (T65P-6A527-A) and coat the end of the stud with Lubriplate. Align the stud and installer with the stud bore, then tap the sliding driver until it bottoms (Fig. 17). When the installer contacts the stud boss, the stud is installed to its correct height. This applies to a 240 or 302 engine only.

EXHAUST CONTROL VALVE—240 AND 300 LD SIX

Removal

1. Separate the intake and exhaust manifolds.
2. Remove the valve tension spring and the thermostatic spring from the exhaust control valve shaft (Fig. 18).
3. Remove the stop pin spring from the manifold.
4. Using an actylene torch inside the manifold, cut the shaft on both sides of the valve plate.
5. Remove the valve plate, shaft and flat washer.
6. Remove the expansion plug from the control valve shaft bushing bore.
7. Remove the exhaust control valve bushings from the manifold. These bushings come in two sizes each, both front and rear. To determine which bushings should be used, measure the outside diameter of the removed bushings. Replace with the proper parts (Fig. 19).

Installation

1. Install the new control valve bushings. The inner end of the smaller bushing should be 0.010-0.015 inch below the inner surface of the exhaust manifold. The inner end of the larger bushing should be 0.020 inch above the inner surface of the exhaust manifold.
2. Ream the bushings to 0.251-0.253 inch ID.
3. Slide the new shaft into the bushings, flat washer and valve plate. The flat washer must be between the valve plate and the large bushing.
4. Install a new stop pin spring on the stop pin.
5. Position the exhaust control valve at an 84 degree angle with the top surface of the manifold (Fig. 20).
6. Rotate the counterweight and shaft assembly clockwise until the counterweight contacts the stop pin spring. Place a 0.030 inch feeler gauge between the counterweight and manifold to maintain the specified clearance while welding.
7. With the plate and counterweight in position, use stainless steel welding rod to tack-weld the valve plate to the shaft.
8. Move the assembly back and forth to check for a binding condition. If there is no binding condition, securely weld the valve plate to the shaft.
9. Install the expansion plug in the manifold bushing bore.
10. Position the new thermostatic spring on the shaft and counterweight assembly so that it will be necessary to wind the spring approximately 1/2 turn in the clockwise direction to hook the open end over the stop pin. Use a 5/16 inch ID piece of tubing to slide the thermostatic spring on the shaft and counterweight assembly. Wind the spring clockwise and hook it over the stop pin.
11. Install a new valve tension spring on the exhaust control valve shaft and the stop pin.

CORE PLUGS

REMOVAL

To remove a large core plug, drill a 1/2 inch hole in the center of the plug

and remove with a clutch pilot bearing puller (Tool T59L-100-B and T58L-101-A) or pry it out with a large drift punch. On a small core plug, drill a 1/4 inch hole in the center of the plug and pry it out with a small pin punch. Clean and inspect the plug bore.

Prior to installing a core plug the plug bore should be inspected for any damage that would interfere with the proper sealing of the plug. If the bore is damaged it will be necessary to true the surface by boring for the next specified oversize plug.

Oversize (OS) plugs are identified by the OS stamped in the flat located on the cup side of the plug.

Coat the plug and/or bore lightly with an oil-resistant (oil galley) or water-resistant (cooling jacket) sealer and install it following the procedure for cup type or expansion type below:

INSTALLATION

Cup-Type

Cup-type core plugs (Fig. 21) are installed with the flanged edge outward. The maximum diameter of this plug is located at the outer edge of the flange. The flange on cup-type plugs flares outward with the largest diameter at the outer (sealing) edge.

It is imperative to pull the plug into the machined bore by using a properly designed tool. Under no circumstances is the plug to be driven into the bore using a tool that contacts the flange. This method will damage the sealing edge and will result in leakage and/or plug blow out.

The flanged (trailing) edge must be below the chamfered edge of the bore to effectively seal the plugged bore.

If the core plug replacing tool has a depth seating surface, do not seat the tool against a non-machined (casting) surface.

Expansion-Type

Expansion-type core plugs (Fig. 21) are installed with the flanged edge inward. The maximum diameter of this plug is located at the base of the flange with the flange flaring inward.

It is imperative to push or drive the plug into the machined bore using a properly designed tool. Under no circumstances is the plug to be driven using a tool that contacts the crowned portion of the plug. This method will expand the plug prior to installation and may damage the plug and/or plug bore.

When installed the trailing (maximum) diameter must be below the chamfered edge of the bore to effectively seal the plugged bore.

If the core plug replacing tool has a depth seating surface, do not seat the tool against a non-machined (casting) surface.

FLYWHEEL RING GEAR—MANUAL-SHIFT TRANSMISSION

Removal

To replace a damaged or worn ring gear, heat the ring gear with a blow torch on the engine side of the gear, and knock it off the flywheel. **Do not hit the flywheel when removing the ring gear.**

Installation

Heat the new ring gear evenly until the gear expands enough to slip onto the flywheel. Make sure the gear is seated properly against the shoulder. **Do not heat any portion of the gear to a temperature higher than 500 degrees F. If this limit is exceeded, the temperature will be removed from the ring gear teeth.**

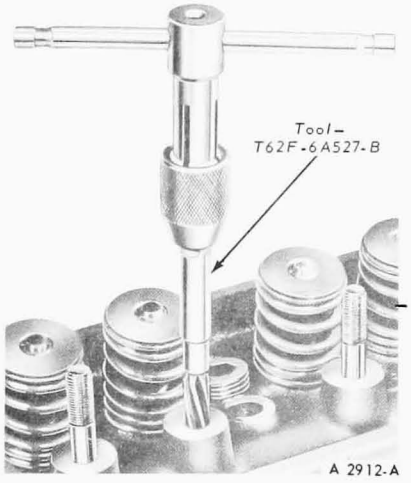

FIG. 16 Reaming Rocker Arm Stud—240 Six and 302 V-8

CRANKSHAFT REAR OIL SEAL

A split-lip type crankshaft rear oil seal is provided for servicing all 1973 engines except 240 and 300 CID. The complete seal is replaced without removing the crankshaft.

Removal

1. Remove the oil pan and the oil pump (if required).
2. Loosen all the main bearing cap bolts, thereby lowering the crankshaft slightly but not to exceed 1/32 inch.
3. Remove the rear main bearing cap, and remove the oil seal from the bearing cap and cylinder block. On the block half of the seal use a seal removal tool, or install a small metal screw in one end of the seal, and pull on the screw to remove the seal. **Exercise caution to prevent scratching or damaging the crankshaft seal surfaces.**
4. Remove the oil seal retaining pin from the bearing cap if so equipped. **The pin is not used with the split-lip seal.**

Installation

1. Carefully clean the seal groove in the cap and block with a brush and solvent.
2. Dip the split lip-type seal halves in clean engine oil.
3. Carefully install the upper seal (cylinder block) into its groove with undercut side of seal toward the FRONT of the engine (Fig. 22), by rotating it on the seal journal of the crankshaft until approximately 3/8 inch protrudes below the parting surface.

Be sure no rubber has been shaved from the outside diameter of the seal by the bottom edge of the groove.

4. Tighten the remaining bearing cap bolts and torque to specifications.

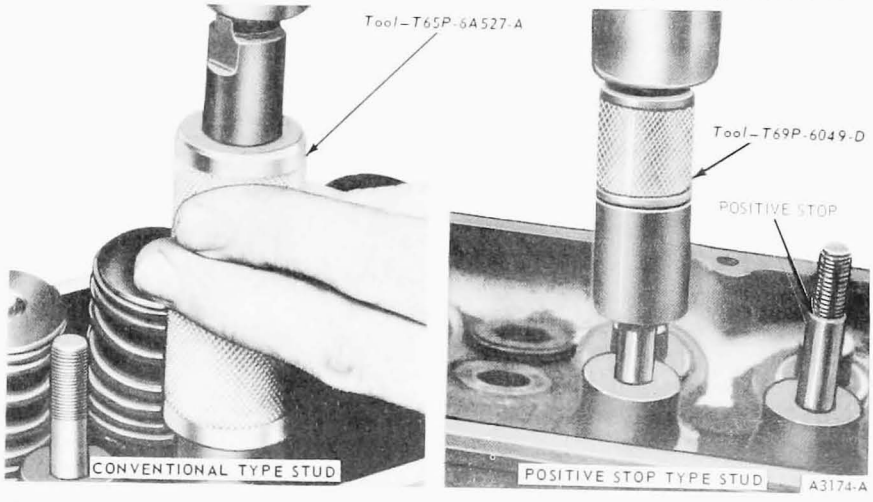

FIG. 17 Installing Rocker Arm Stud—240 Six and 302-W V-8

5. Install the lower seal in the rear main bearing cap with undercut side of seal toward the FRONT of the engine (Fig. 22), allow the seal to protrude approximately 3/8 inch above the parting surface to mate with the upper seal when the cap is installed.
6. Apply a thin coating of oil-resistant sealer to the rear main bearing cap at the rear of the top mating surface. **Do not apply sealer to the area forward of the side seal groove. Install the rear main bearing cap. Torque the cap bolts to specifications.**
7. Install the oil pump and oil pan. Fill the crankcase with the proper amount of viscosity oil.
8. Operate the engine and check for oil leaks.

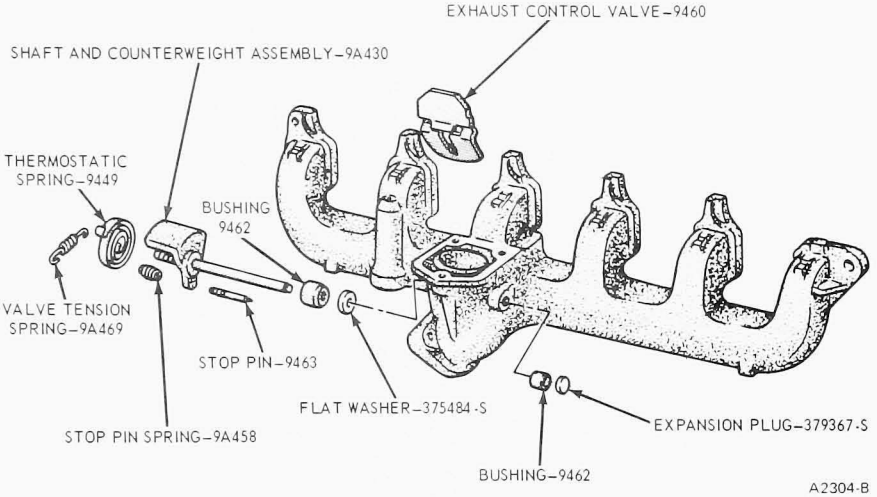

FIG. 18 Exhaust Control Valve Assembly

Part Number	Bushing	Outside Diameter of Bushing	Inside Diameter of Bushing Bore in Manifold
(Front–Std.)	C5AZ-9462-A	0.3070-0.3065	0.3061-0.3051
(Rear–Std.)	C5AZ-9462-B	0.6255-0.6250	0.6246-0.6236
(Front–0.010 O.S.)	C5AZ-9462-C	0.3170-0.3165	0.3161-0.3151
(Rear–0.010 O.S.)	C5AZ-9462-D	0.6355-0.6350	0.6346-0.6336

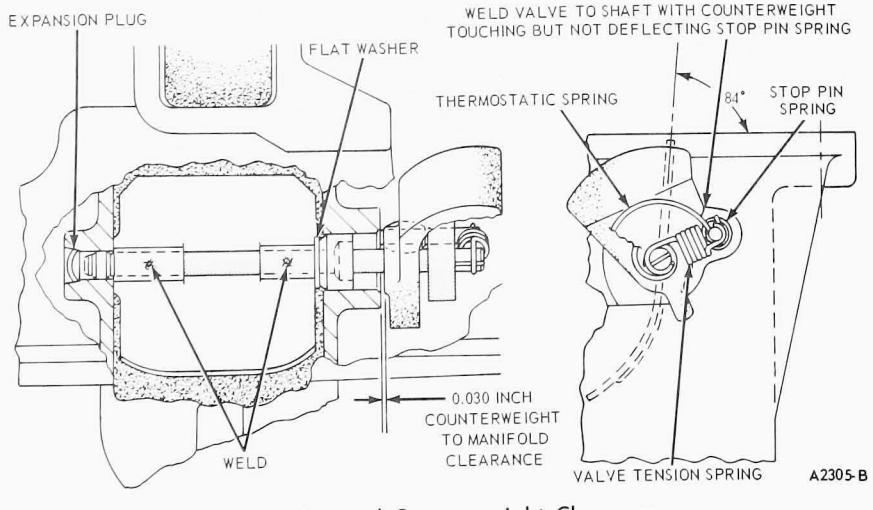

FIG. 20 Valve Plate Position and Counterweight Clearance

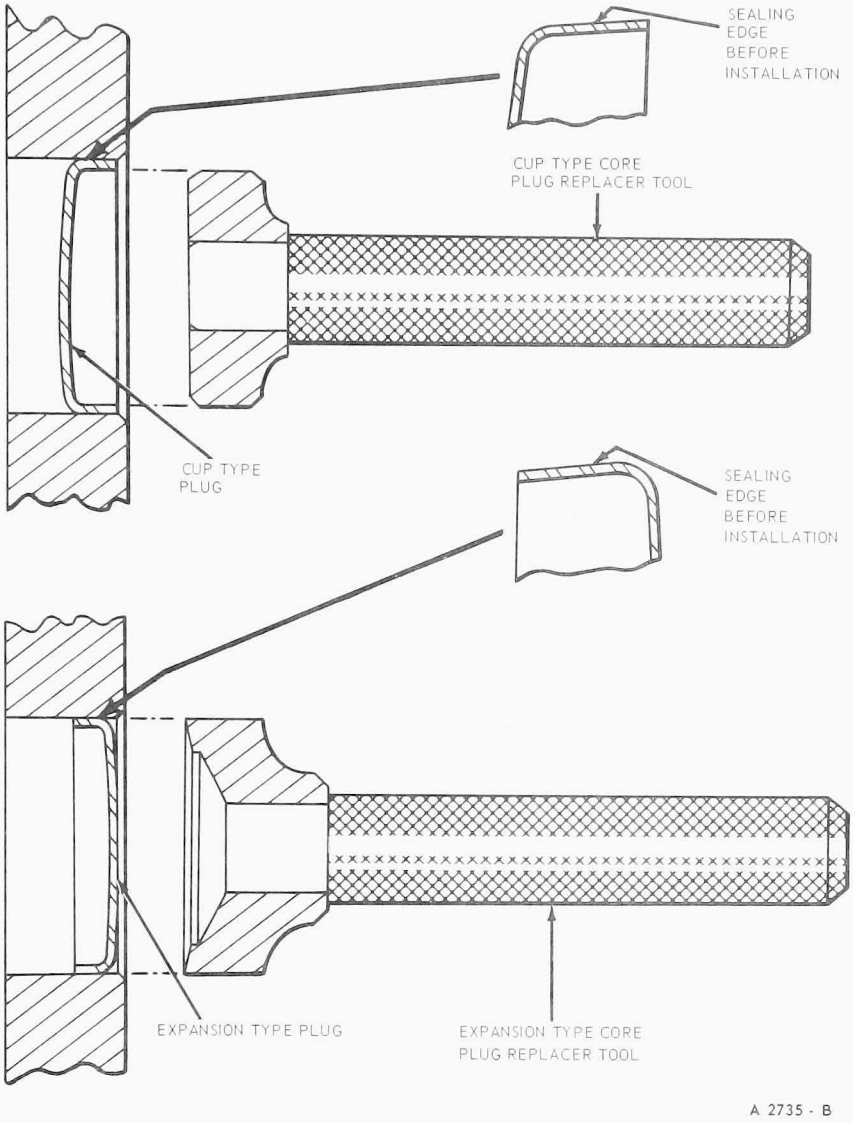

FIG. 21 Typical Core Plugs and Installation Tools

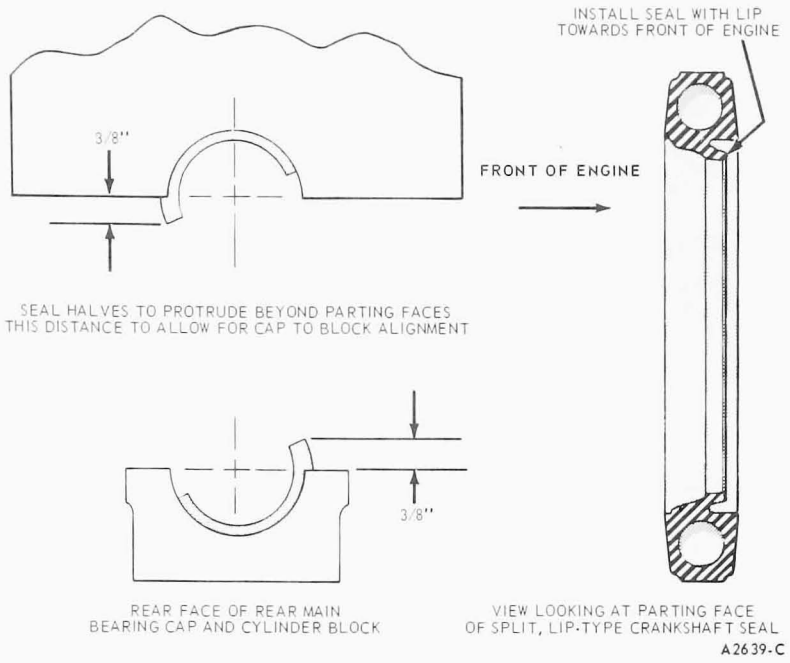

FIG. 22 Installing Crankshaft Rear Oil Seal

OVERHUAL

CYLINDER HEAD

Replace the head if it is cracked. **Do not plane or grind more than 0.010 inch from the cylinder head gasket surface.** Remove all burrs or scratches with an oil stone.

REAMING VALVE GUIDES

If it becomes necessary to ream a valve guide (Fig. 23) to install a valve with an oversize stem, a reaming kit is available which contains the following reamer and pilot combinations: a 0.003 inch OS reamer with a standard diameter pilot, a 0.015 inch OS reamer with a 0.003 inch OS pilot, and a 0.030 inch reamer with a 0.015 inch OS pilot.

When going from a standard size valve to an oversize valve always use the reamer in sequence. **Always reface the valve seat after the valve guide has been reamed, and use a suitable scraper to break the sharp corner (ID) at the top of the valve guide.**

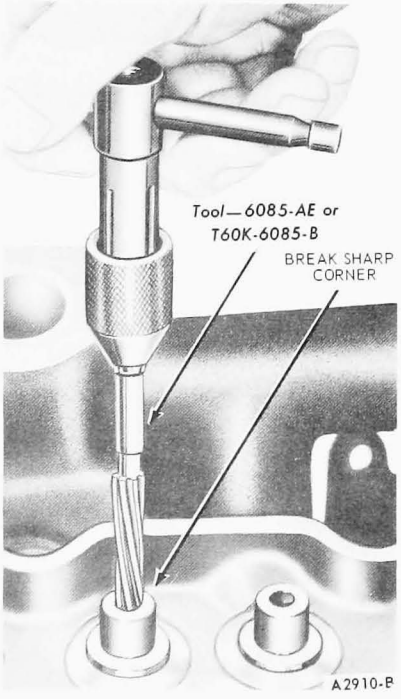

FIG. 23 Reaming Valve Guides

REFACING VALVE SEATS

Refacing of the valve seat should be closely coordinated with the refacing of the valve face so that the finished seat and valve face will be concentric and the specified interference fit will be maintained. This is important so that the valve and seat will have a compression tight fit. Be sure that the refacer grinding wheels are properly dressed.

Grind the valve seats of all engines to a true 45 degree angle (Fig. 24). Remove only enough stock to clean up pits and grooves or to correct the valve seat runout. After the seat has been refaced, use a seat width scale or a machinist scale to measure the seat width (Fig. 25). Narrow the seat, if necessary to bring it within specifications.

If the valve seat width exceeds the maximum limit, remove enough stock from the top edge and/or bottom edge of the seat to reduce the width to specifications.

On the valve seats of all engines use a 60 degree angle grinding wheel to remove stock from the bottom of the seats (raise the seats) and use a 30 degree angle wheel to remove stock from the top of the seats (lower the seats).

The finished valve seat should contact the approximate center of the valve face. It is good practice to determine where the valve seat contacts the face. To do this, coat the seat with Prussian blue and set the valve in place. Rotate the valve with light pressure. If the blue is transferred to the center of the valve face, the contact is satisfactory. If the blue is transferred to the top edge of the valve face, lower the valve seat. If the blue is transferred to the bottom edge of the valve face, raise the valve seat.

VALVES

Minor pits, grooves, etc., may be removed. Discard valves that are severely damaged, or if the face runout cannot be corrected by refinishing or if stem clearance exceeds specifications.

Discard any worn or damaged valve train parts.

Refacing Valves

The valve refacing operation should be closely coordinated with the valve seat refacing operations so that the finished angles of the valve face and of the valve seat will be to specifications and provide a compression-tight fit. Be sure that the refacer grinding wheels are properly dressed.

If the valve face runout is excessive and/or to remove pits and grooves, reface the valves to a true 44 degree angle. Remove only enough stock to correct the runout or to clean up the pits and grooves. If the edge of the valve head is less than 1/32 inch thick after grinding (Fig. 26), replace the valve as the valve will run too hot in the engine. **The interference fit of the valve and seat should not be lapped out.**

Remove all grooves or score marks from the end of the valve stem, and chamfer it as necessary. Do not remove more than 0.010 inch from the end of the valve stem.

If the valve and/or valve seat has been refaced, it will be necessary to check the clearance between the rocker arm pad and the valve stem with the valve train assembly installed in the engine.

Select Fitting Valves

If the valve stem to valve guide clearance exceeds the wear limit, ream the valve guide for the next oversize valve stem. Valves with oversize stem diameters of 0.003, 0.015 and 0.030 inch are available for service. **Always reface the valve seat after the valve guide has been reamed. Refer to Reaming Valve Guides.**

CAMSHAFT REPAIR

Remove light scuffs, scores or nicks from the camshaft machined surfaces with a smooth oil stone.

CRANKSHAFT

Dress minor scores with an oil stone. If the journals are severely marred or exceed the wear limit, they should be refinished to size for the next undersize bearing.

Refinishing Journals

Refinish the journals to give the proper clearance with the next undersize bearing. If the journal will not clean up to maximum undersize bearing available, replace the crankshaft.

Always reproduce the same journal shoulder radius that existed originally. Too small a radius will result in fatigue failure of the crankshaft. Too large a radius will result in bearing failure due to radius ride of the bearing.

After refinishing the journals, chamfer the oil holes; then polish the journal with a No. 320 grit polishing cloth and engine oil. Crocus cloth may also be used as a polishing agent.

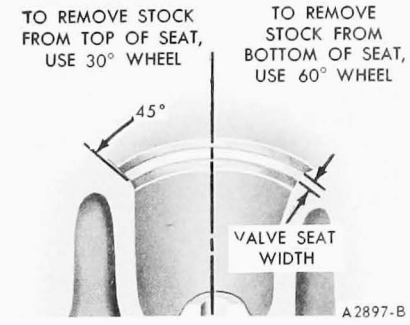

FIG. 24 Refacing Valve Seat

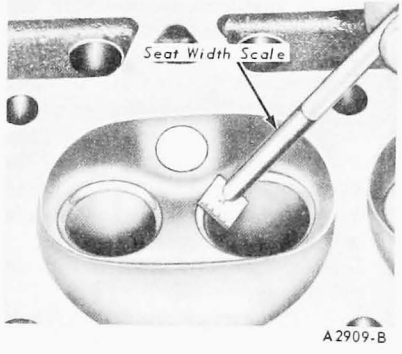

FIG. 25 Checking Valve Seat Width

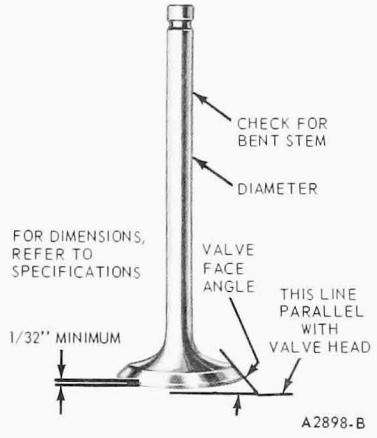

FIG. 26 Critical Valve Dimensions

FITTING MAIN OR CONNECTING ROD BEARINGS WITH PLASTIGAGE

1. Clean crankshaft journals. Inspect journals and thrust faces (thrust bearing) for nicks, burrs or bearing pick-up that would cause premature bearing wear. When replacing standard bearings with new bearings, it is good practice to fit the bearing to minimum specified clearance. If the desired clearance cannot be obtained with a standard bearing, try one half of a 0.001 or 0.002 inch undersize in combination with a standard bearing to obtain the proper clearance.
2. If fitting a main bearing, position a jack under counterweight adjoining bearing which is being checked. **Do not place jack under front post of crankshaft.** Support crankshaft with jack so its weight will not compress Plastigage and provide an erroneous reading.
3. Place a piece of Plastigage on bearing surface across full width of bearing cap and about 1/4 inch off center (Fig. 27).
4. Install cap and torque bolts to specifications. Do not turn crankshaft while Plastigage is in place.
5. Remove cap. Using Plastigage scale, check width of Plastigage at widest point to get minimum clearance. Check at narrowest point to get maximum clearance. Difference between readings is taper of journals.
6. If clearance exceeds specified limits, try 0.001 or 0.002 inch undersize bearings in combination with the

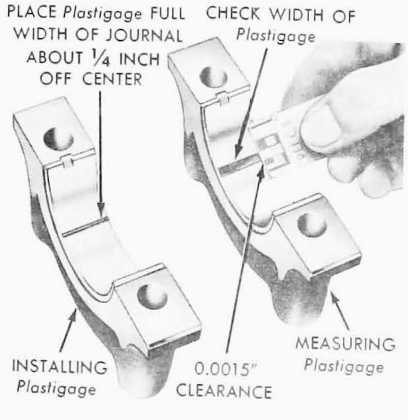

FIG. 27 Installing and Measuring Plastigage—Engine Installed

standard bearings. Bearing clearance must be within specified limits. If 0.002 undersize main bearings are used on more than one journal, be sure they are all installed in cylinder block side of bearing. If standard and 0.002 inch undersize bearings do not bring clearance within desired limits, refinish crankshaft journal, then install undersize bearings.

7. After bearing has been fitted, apply light coat of engine oil to journal and bearings. Install bearing cap. Torque cap bolts to specifications.
8. Repeat procedures for remaining bearings that require replacement.

PISTONS, PINS AND RINGS

Fitting Pistons

Pistons are available for service in standard sizes and the oversizes shown in Fig. 28.

The standard size pistons are color coded red or blue, or have 0.003 O.S. stamped on the dome. Refer to the Specifications for standard size piston dimensions.

Measure the cylinder bore and select the piston to assure the proper clearance. When the bore diameter is in the lower one third of the specified range, a red piston should be used. When the bore diameter is in the middle one third a blue piston should be used. When the bore diameter is in the upper one third, the 0.003 O.S. piston should be used.

Measure the piston diameter to ensure that the specified clearance is obtained. It may be necessary periodically to use another piston (within the same grade size) that is either slightly larger, or smaller to achieve the specified clearance.

If none can be fitted, refinish the cylinder to provide the proper clearance for the piston.

When a piston has been fitted, mark it for assembly in the cylinder to which it was fitted.

If the taper, out-of-round and piston to cylinder bore clearance conditions of the cylinder bore are within specified limits, new piston rings will give satisfactory service. If new rings are to be installed in a used cylinder that has not been refinished, remove the cylinder wall glaze (Refer to Cylinder Block, Refinishing Cylinder Walls). Be sure to clean the cylinder bore thoroughly.

1. Calculate the size piston to be used by taking a cylinder bore check. Follow the procedures outlined under Cleaning and Inspection.
2. Select the proper size piston to provide the desired clearance (refer to the specifications). Measure the piston diameter in line with the centerline of the piston pin and at 90 degrees to the piston pin axis.
3. Make sure the piston and cylinder block are at room temperature (70 degrees F). **After any refinishing operation allow the cylinder bore to cool, and make sure the piston and bore are clean and dry before the piston fit is checked.**
1. Select the proper ring set for the size cylinder bore.
2. Position the ring in the cylinder bore in which it is going to be used.
3. Push the ring down into the bore area where normal ring wear is not encountered.
4. Use the head of a piston to position the ring in the bore so that the ring is square with the cylinder wall. **Use caution to avoid damage to the ring or cylinder bore.**
5. Measure the gap between the ends of the ring with a feeler gauge (Fig. 29). If the ring gap is less or greater than the specified limits, try another ring set.
6. Check the ring side clearance of the compression rings with a feeler gauge inserted between the ring and its lower land (Fig. 30). The gauge should slide freely around the entire ring circumference without binding. Any wear that occurs will form a step at the inner portion of the lower land. **If the lower lands have high steps, the piston should be replaced.**

Engine	Piston Oversize (Inch)
Six 200, 240 and 300	0.020, 0.030 and 0.040
V-8 302, 330, 360, 361, 390, 391, 401, 477 and 534	0.020, 0.030 and 0.040

CA1341-A

FIG. 28 Oversize Service Pistons

FITTING PISTON PINS—330, 360, 361, 390 AND 391 HD V-8

The piston pin should be a light thumb press fit at normal temperature (70 degrees F). Standard piston pins are color coded green. Pins of 0.001 inch oversize (color coded blue) and 0.002 inch oversize (color coded yellow) are available.

Install the piston pin in the piston and rod. Install a new retainer at each end of the pin to hold it in place. Make sure the retainers are properly seated in their grooves.

If the pin hole in the piston must be reamed or honed, use precision honing equipment or an expansion-type, piloted reamer. **Piston pin bores must not be reamed with hand-driven reamers. Use motor-driven reamers, but do not exceed the cutting speed (rpm) recommended by the reamer manufacturer.**

If a reamer is used, set the reamer to the size of the pin bore; then expand the reamer slightly and trail ream the pin bore. Take a light cut. Use a pilot sleeve of the nearest size to maintain alignment of the bores.

Check the hole size, using the new piston pin. If the bore is small, expand the reamer slightly and make another cut. Repeat the procedure until the proper fit is obtained. Check the piston pin for fit in the respective rod or rod bushing. If necessary, ream or hone the rod bushing to fit the pin to specifications.

FITTING PISTON PINS—ALL EXCEPT 330, 360, 361, 390 AND 391 HD V-8

On all engines except those above, install the piston pin, following the procedure under Piston Assembly in the applicable engine Part.

VALVE ROCKER ARM AND/OR SHAFT ASSEMBLY

Dress up minor surface defects on the rocker arm shaft and in the rocker arm bore with a hone (200, Six and 330, 360, 361, 390 and 391 V-8 only).

If the pad at the valve end of the rocker arm has a grooved radius, replace the rocker arm. **Do not attempt to true this surface by grinding.**

Refer to Removal and Installation for the rocker arm stud replacement procedure.

PUSH RODS

Following the procedures under Push Rod Inspection, check the push rods for straightness.

If the runout exceeds the maximum limit at any point, discard the rod. **Do not attempt to straighten push rods.**

CYLINDER BLOCK

Refinishing Cylinder Walls

Honing is recommended for refinishing cylinder walls only when the walls have minor scuffs or scratches, or for fitting pistons to the specified clearance. The grade of hone to be used is determined by the amount of metal to be removed. Follow the instructions of the hone manufacturer. If coarse stones are used to start the honing operation, leave enough material so that all hone marks can be removed with the finishing hone which is used to obtain the proper piston clearance.

Cylinder walls that are severely marred and/or worn beyond the specified limits should be refinished. **Before any cylinder is refinished, all main bearing caps must be in place and tightened to the proper torque so that the crankshaft bearing bores will not become distorted from the refinishing operation.**

Refinish only the cylinder or cylinders that require it. All pistons are the same weight, both standard and oversize; therefore, various sizes of pistons can be used without upsetting engine balance.

Refinish the cylinder with the most wear first to determine the maximum oversize. If the cylinder will not clean up when refinished for the maximum oversize piston recommended, replace the block.

Refinish the cylinder to within approximately 0.0015 inch of the required oversized diameter. This will allow enough stock for the final step of honing so that the correct surface finish and pattern are obtained.

For the proper use of the refinishing equipment, follow the instructions of the manufacturer. Only experienced personnel should be allowed to perform this work.

Use a motor-driven, spring pressure-type hone at a speed of 300-500 rpm. Hones of grit sizes 180-220 will normally provide the desired bore surface finish. When honing the cylinder bores, use a lubricant mixture of equal parts of kerosene and SAE No. 20 MOTOR OIL. Operate the hone in such a way as to produce a cross-hatch finish on the cylinder bore. The cross-hatch pattern should be at an angle of approximately 30 degrees to the cylinder bore. After the final operation in either of the two refinishing methods described and prior to checking the piston fit, thoroughly clean and oil the cylinder walls. Mark the pistons to correspond to the cylinders in which they are to be installed. When the refinishing of all cylinders that require it has been completed and all pistons are fitted, thoroughly clean the entire block and oil the cylinder walls.

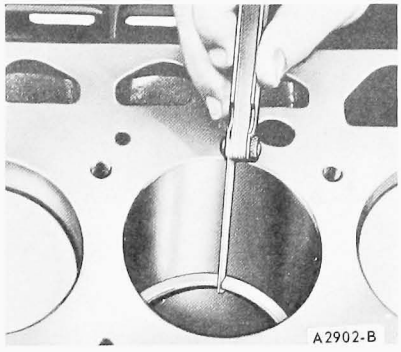

FIG. 29 Checking Piston Ring Gap

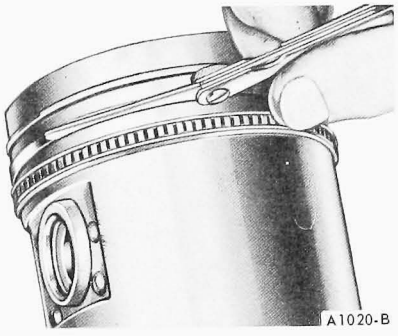

FIG. 30 Checking Piston Ring Side Clearance

Repairing Engine Castings Having Sand Holes or Being Porous

Porosity or sand hole(s) which will cause oil seepage or leakage can occur with modern casting processes. A complete inspection of engine and transmission should be made. If the leak is attributed to the porous condition of the cylinder block or sand hole(s), repairs can be made with metallic plastic (Part No. C6AZ-19554-A). **Do not repair cracks with this material. Repairs with this metallic plastic must be confined to those case iron engine component surfaces (Fig. 31) where the inner wall surface is not exposed to engine coolant pressure or oil pressure, for example:**

1. Cylinder block surfaces extending along the length of the block, upward from the oil pan rail to the cylinder water jacket but not including machined areas.
2. Lower rear face of the cylinder block.
3. Intake manifold casting. Repairs are not recommended to the intake manifold exhaust crossover section since temperature can exceed the recommended temperature limit of 500 degrees F.
4. Cylinder front cover on engines using cast iron material.
5. Cylinder head, along the rocker arm cover gasket surface.

The following procedures should be used to repair porous areas or sand holes in cast iron:

1. Clean the surface to be repaired by grinding or rotary filling to a clean bright metal surface. Chamfer or undercut the hole or porosity to a greater depth than the rest of the cleaned surface. Solid metal must surround the hole. Openings larger than 1/4 inch should not be repaired using metallic plastic. Openings in excess of 1/4 inch can be drilled, tapped and plugged using common tools. Clean the repair area thoroughly. Metallic plastic will not stick to a dirty or oil surface.
2. Mix the metallic plastic base and hardener as directed on the container. Stir thoroughly until uniform.
3. Apply the repair mixture with a suitable clean tool (putty knife, wood spoon, etc.) forcing the epoxy into the hole or porosity.
4. Allow the repair mixture to harden. This can be accomplished by two methods; heat cure with a 250 degree watt lamp placed 10 inches from the repaired surface, or air dry for 10-12 hours at temperatures above 50 degrees F.
5. Sand or grind the repaired area to blend with the general contour of the surrounding surface.
6. Paint the surface to match the rest of the block.

CLEANING AND INSPECTION

The cleaning and inspection procedures are for a complete engine overhaul; therefore, for partial engine overhaul or parts replacement, follow the pertinent cleaning or inspection procedure.

INTAKE MANIFOLD

Cleaning

Remove all gasket material from the machined surfaces of the manifold. Clean the manifold in a suitable solvent and dry it with compressed air.

Inspection

Inspect the manifold for cracks, nicked gasket surfaces, or other damage that would make it unfit for further service. Replace all studs that are stripped or otherwise damaged. **Remove all filings and foreign matter that may have entered the manifold as a result of repairs.**

On a 330, 360, 361 and 391 V-8 check the baffle plate on the underside of the manifold; it should be securely fastened at all retaining points.

EXHAUST MANIFOLDS

Cleaning

Remove all gasket material from the manifold(s).

Inspection

On the 240 six and 300 LD six engines, check the exhaust control valve for freedom from binding throughout the valve travel. If necessary, free the shaft with exhaust control valve solvent. If the solvent does not eliminate the binding condition, replace the component parts (Refer to Exhaust Control Valve Replacement—240 and 300 LD Six).

Inspect the manifold(s) for cracks, damaged gasket surfaces, or other defects that would make them unfit for further service. Inspect the cylinder head joining flanges of the exhaust manifold(s) for evidence of exhaust gas leaks.

VALVE ROCKER ARM AND/OR SHAFT ASSEMBLY

Cleaning

Clean all the parts thoroughly. Make sure that all oil passages are open.

On ball stud rocker arms, make sure the oil passage in the push rod end of the rocker arm is open.

If necessary, remove the plugs from both ends of the rocker arm shaft to thoroughly clean the shaft passages.

Inspection

On rocker arm shaft assemblies, check the clearance between each rocker arm and the shaft by checking the ID of the rocker arm bore and the OD of the shaft. If the clearance between any rocker arm and the shaft exceeds specified limits, replace the shaft and/or the rocker arm. Inspect the shaft and the rocker arm bore for nicks, scratches, scores, or scuffs.

Inspect the pad at the valve end of the rocker arms for indications of scuffing or abnormal wear. If the pad is grooved, replace the rocker arm. **Do not attempt to true this surface by grinding.**

Check the rocker arm adjusting screws and the push rod end of the rocker arms for stripped or broken threads, and the ball end of the adjusting screw for nicks, scratches, or excessive wear.

On the ball stud rocker arms, check the rocker arm and fulcrum seat for excessive wear, cracks, nicks or burrs. Check the rocker arm stud and nut for stripped or broken threads.

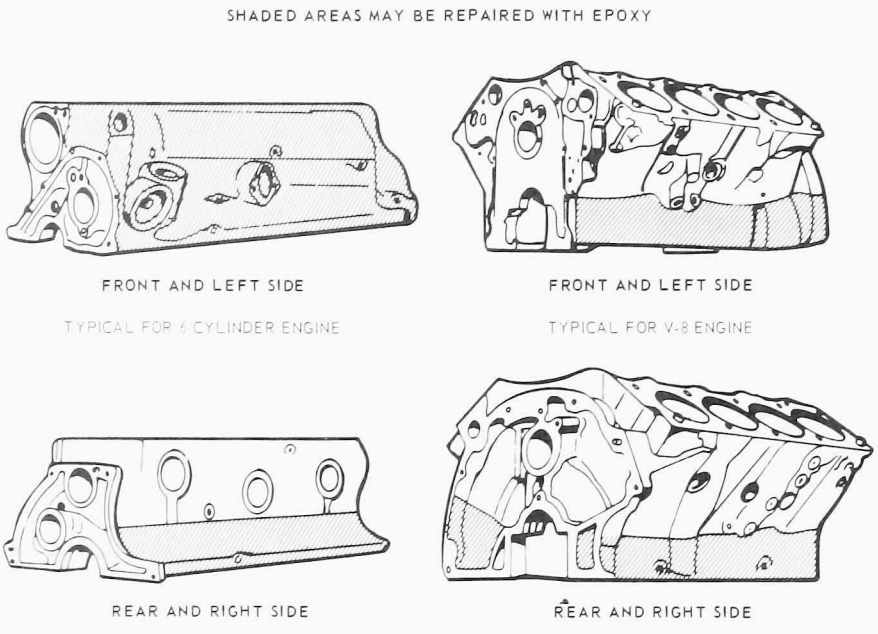

FIG. 31 Typical Cast Iron Cylinder Block Areas Repairable with Metallic Plastic

VALVE ROCKER ARM COVERS

Check the gasket surfaces for damage caused by over-torqued bolts. Straighten the surface as required to restore original flatness.

PUSH RODS

Cleaning

On a 240 or 300 Six or 302 V-8 engines, clean the push rods in a suitable solvent. Blow out the oil passage in the push rod with compressed air.

Inspection

Check the ends of the push rods for nicks, grooves, roughness or excessive wear.

The push rods can be visually checked for straightness while they are installed in the engine by rotating them with the valve closed. They also can be checked with a dial indicator (Fig. 32).

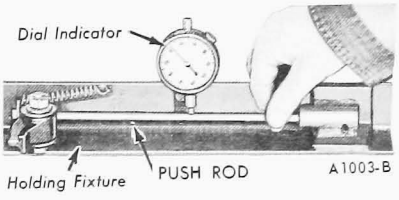

FIG. 32 Checking Push Rod Runout

CYLINDER HEADS

Cleaning

With the valves installed to protect the valve seats, remove deposits from the combustion chambers and valve heads with a scraper and a wire brush. **Be careful not to damage the cylinder head gasket surface.** After the valves are removed, clean the valve guide bores with a valve guide cleaning tool. Using cleaning solvent to remove dirt, grease and other deposits, clean all bolt holes; be sure the oil transfer passage is clean (V-8 engines).

Remove all deposits from the valves with a fine wire brush or buffing wheel.

Inspection

Inspect the cylinder heads for cracks or excessively burned areas in the exhaust outlet ports.

FIG. 33 Checking Cylinder Head Flatness

Check the cylinder head for cracks and inspect the gasket surface for burrs and nicks. Replace the head if it is cracked.

On a 300, 361 and 391 HD V-8 and 401, 477 or 534 SD V-8 engine, check the valve seat inserts for excessive wear, cracks or looseness.

The following inspection procedures are for a cylinder head that is to be completely overhauled. For individual repair operations, use only the pertinent inspection procedure.

Cylinder Head Flatness

When a cylinder head is removed because of gasket leaks, check the flatness of the cylinder head gasket surface (Fig. 33) for conformance to specifications. If necessary to refinish the cylinder head gasket surface, **do not plane or grind off more than 0.010 inch from the original gasket surface.**

Valve Seat Runout

Check the valve seat runout with an accurate gauge (Fig. 34). Follow the instructions of the gauge manufacturer. If the runout exceeds the wear limit, reface the valve and valve seat.

Valve Seat Width

Measure the valve seat width (Fig. 25). Reface the valve seat(s) if the width is not within specifications.

Valves

The critical inspection points and tolerances of the valve are illustrated in Fig. 26. Refer to specifications for wear limits.

Inspect the valve face and the edge of the valve head for pits, grooves or scores. Inspect the stem for a bent condition and the end of the stem for grooves or scores. Check the valve head for signs of burning or erosion, warpage and cracking. Minor pits, grooves, etc., may be removed. Discard severely damaged valves.

Do not discard sodium-cooled valves (330, 361 and 391 HD V-8 or 401, 477 or 534 SD V-8 exhaust valves) with other scrap metal in scrap bins. If a sodium-cooled valve is accidentally broken and the sodium exposed, it will react violently upon contact with water resulting in fire and explosion due to chemical action. Therefore, these valves should be handled with care and disposed of by being buried in the ground in an area not subjected to excavation.

Inspect the valve springs, valve spring retainers, locks and sleeves and discard any visually damaged parts.

Valve Face Runout

Check the valve face runout. It should not exceed the specified wear limit. If the runout exceeds the wear limit, the valve should be replaced or refaced as outlined under Refacing Valves in this section.

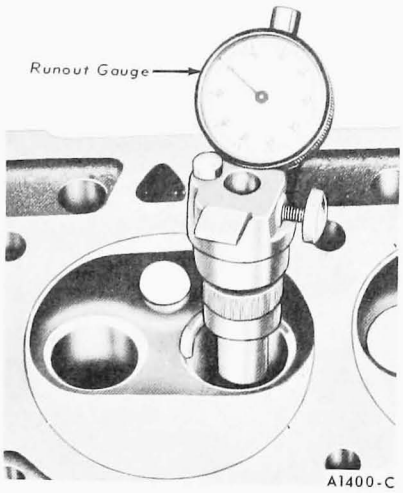

FIG. 34 Checking Valve Seat Runout

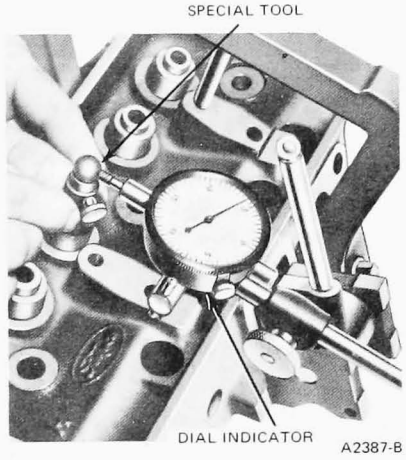

FIG. 35 Checking Valve Stem Clearance

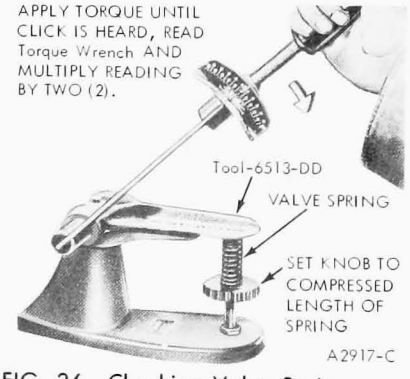

FIG. 36 Checking Valve Spring Pressure

Valve Stem Clearance

Check the valve stem to valve guide clearance of each valve in its respective valve guide with the tool shown in Fig. 35 or its equivalent. Use a flat end indicator point.

Install the tool on the valve stem until it is fully seated, and tighten the knurled set screw firmly. Permit the valve to drop away from its seat until the tool contacts the upper surface of the valve guide.

Position the dial indicator with its flat tip against the center portion of the tool's spherical section at approximately 90 degrees to the valve stem axis. Move the tool back and forth in line with the indicator stem. Take a reading on the dial indicator without removing the tool from the valve guide upper surface. Divide the reading by two, the division factor for the tool.

Valve Spring Pressure

Check the valve spring for proper pressure (Fig. 36) at the specified spring lengths. Weak valve springs cause poor performance; therefore, if the pressure of any spring is lower than the wear limit, replace the spring.

Valve Spring Squareness

Check each spring for squareness using a steel square and a surface plate (Fig. 37). Stand the spring and square on end on the surface plate. Slide the spring up to the square. Rotate the spring slowly and observe the space between the top coil of the spring and square. If the spring is out of square more than 5/64 inch, replace it.

Follow the same procedure to check new valve springs before installation.

Make certain the proper spring (color coded) is installed.

HYDRAULIC VALVE LIFTERS

The valve lifter assemblies should be kept in proper sequence so that they can be installed in their original position. Inspect and test each lifter separately so as not to intermix the internal parts. **If any part of the lifter assembly needs replacing, replace the entire assembly.**

Cleaning

Thoroughly clean all the parts in clean solvent and wipe them with a clean, lint-free cloth.

Inspection

Inspect the parts and discard the entire lifter assembly if any part shows pitting, scoring, galling or evidence of non-rotation. Replace the entire assembly if the plunger is not free in the body. The plunger should drop to the bottom of the body by its own weight when assembled dry.

Assemble the lifter assembly and check for freeness of operation by pressing down on the push rod cup. The lifters can also be checked with a hydraulic tester to test the leak-down rate. Follow the instructions of the test

unit manufacturer or the procedure in this Part.

MECHANICAL TAPPETS

Cleaning

Thoroughly clean the tappets in clean solvent and wipe them with a clean, lint-free cloth.

Inspection

Inspect the tappets, and discard any that show signs of pitting, scoring or galling. Replace any tappets that show evidence of non-rotation.

CRANKSHAFT VIBRATION DAMPER AND SLEEVE

Cleaning

Clean the oil seal contact surface on the crankshaft damper or sleeve with solvent to remove any corrosion, sludge or varnish deposits. Excess deposits that are not readily removed with solvent may be removed with crocus cloth. Use crocus cloth to remove any sharp edges, burrs or other imperfections which might damage the oil seal during installation or cause premature seal wear. **Do not use crocus cloth to the extent that the seal surface becomes polished. A finely polished surface may produce poor sealing or cause premature seal wear.**

Inspection

Inspect the crankshaft damper or sleeve oil seal surface for nicks, sharp edges or burrs that might damage the oil seal during installation or cause premature seal wear.

TIMING CHAIN AND SPROCKETS

Cleaning

Clean all parts in solvent and dry them with compressed air.

Lubricate the timing chain with engine oil before installing it on the engine.

Inspection

Inspect the chain for broken links. Inspect the sprockets for cracks and worn or damaged teeth. Replace all the components of the timing chain and sprocket assembly, if any one item needs replacement.

Inspect the fuel pump drive eccentric for scores, nicks and excessive wear. If the eccentric is scored, replace it.

TIMING GEARS

Cleaning

Clean the gears in solvent and dry them with compressed air.

Inspection

Inspect the gear teeth for scores, nicks, etc. Note the condition of the teeth contact pattern. If the teeth are scored, replace the gears.

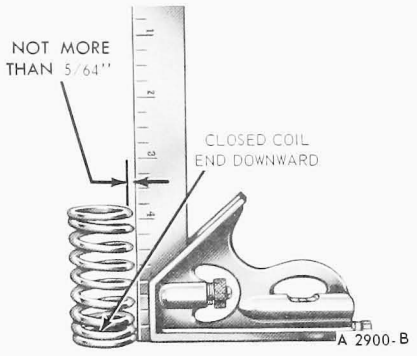

FIG. 37 Checking Valve Spring Squarenes

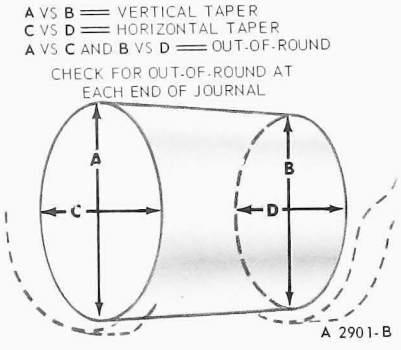

FIG. 38 Crankshaft Journal Measurement

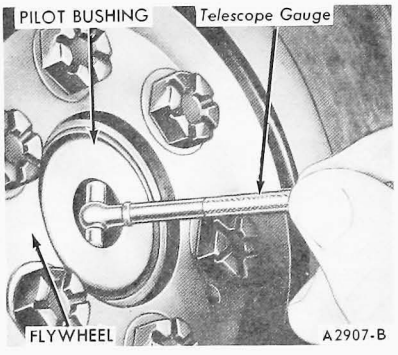

FIG. 39 Measuring Clutch Pilot Bushing Wear

It is not necessary to replace the gears in sets. Replace the camshaft gear and check the backlash, runout, etc., to determine if the crankshaft gear should be replaced.

CAMSHAFT

Cleaning and Inspection

Clean the camshaft in solvent and wipe it dry. Inspect the camshaft lobes for scoring and signs of abnormal wear. Lobe wear characteristics may result in pitting in the general area of the lobe toe. This pitting is not detrimental to the operation of the camshaft; therefore, the camshaft should not be replaced unless the camshaft lobe lift loss has exceeded 0.005 inch.

The lift of camshaft lobes can be checked with the camshaft installed in the engine or on centers. Refer to Camshaft Lobe Lift.

Check the distributor drive gear for broken or chipped teeth.

Check the fuel pump eccentric (if so equipped) for excessive wear.

CRANKSHAFT

Cleaning

Handle the crankshaft with care to avoid possible fractures or damage to the finish surfaces. Clean the crankshaft with solvent, and blow out all oil passages with compressed air.

On a 240 or 300 Six clean the oil seal contact surface at the rear of the crankshaft with solvent to remove any corrosion, sludge or varnish deposits. Excess deposits that are not readily removed with solvent may be removed with crocus cloth. Use crocus cloth to remove any sharp edges, burrs or other imperfections which might damage the oil seal during installation or cause premature seal wear. **Do not use crocus cloth to the extent that the seal surfaces become polished. A finely polished surface may produce poor sealing or cause premature seal wear.**

Inspection

Inspect the main and connecting rod journals for cracks, scratches, grooves or scores.

Measure the diameter of each journal at least four places to determine out-of-round, taper or undersize condition (Fig. 38).

On an engine used with a manual shift transmission, check the fit of the clutch pilot bushing in the bore of the crankshaft. The bushing is pressed into the crankshaft and should not be loose. Inspect the inner surface of the bushing for wear or a bell-mouth condition. Check the ID of the bushing (Fig. 39). Replace the bushing if it is damaged or the ID is not within specifications.

Inspect the pilot bearing, when used, for roughness, evidence of overheating or loss of lubricant. Replace if any of these conditions are found.

On the 240 and 300 Six engines, inspect the rear oil seal surface of the crankshaft for excessively deep grooves, nicks, burrs, porosity, or scratches which could damage the oil seal lip during installation. Remove all nicks and burrs and polish the chamfered edge and oil seal contact surface with crocus cloth.

FLYWHEEL-MANUAL-SHIFT TRANSMISSIONS

Inspection

Inspect the flywheel for cracks, heat checks, or other damage that would make it unfit for further service. Machine the friction surface of the flywheel if it is scored or worn. If it is necessary to remove more than 0.045 inch of stock from the original thickness, replace the flywheel.

Inspect the ring gear for worn, chipped, or cracked teeth. If the teeth are damaged, replace the ring gear.

With the flywheel installed on the crankshaft, check the flywheel face runout, following the procedure in this Part.

FLYWHEEL-AUTOMATIC TRANSMISSION

Inspection

Inspect the flywheel for cracks or other damage that would make it unfit for further service. Inspect the starter ring gear for worn, chipped or cracked teeth. If the teeth are damaged, replace the starter ring gear and flywheel assembly.

With the flywheel installed on the crankshaft, check the gear face runout of the flywheel (Refer to Diagnosis and Testing for the proper procedure).

CONNECTING RODS

Cleaning

Remove the bearings from the rod and cap. Identify the bearing if they are to be used again. Clean the connecting rod in solvent, including the rod bore and the back of the inserts. **Do not use a caustic cleaning solution. Blow out all passages with compressed air.**

Inspection

The connecting rods and related parts should be carefully inspected and checked for conformance to specifications. various forms of engine wear caused by these parts can be readily identified.

A shiny surface on the pin boss side of the piston usually indicates that a connecting rod is bent or the piston pin hole is not in proper relation to the piston skirt and ring grooves.

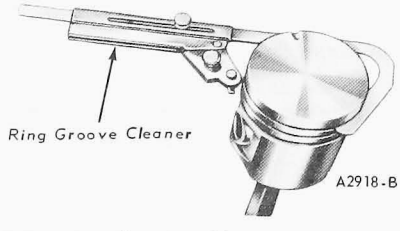

FIG. 40 Cleaning Ring Grooves—Typical

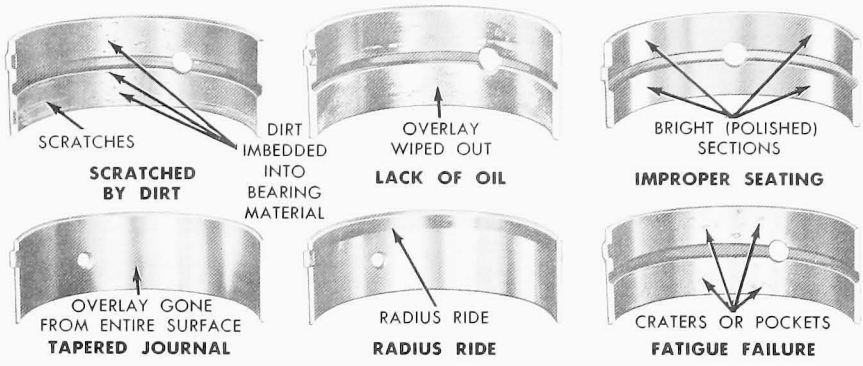

FIG. 41 Typical Bearing Failures

Abnormal connecting rod bearing wear can be caused by either a bent connecting rod, an improperly machined journal, or a tapered connecting rod bore.

Twisted connecting rods will not create an easily identifiable wear pattern, but badly twisted rods will disturb the action of the entire piston, rings, and connecting rod assembly and may be the cause of excessive oil consumption.

Inspect the connecting rods for signs of fractures and the bearing bores for out-of-round and taper. If the bore exceeds the maximum limit and/or if the rod is fractured, it should be replaced.

On connecting rods that have a piston pin bushing, check the piston pin to connecting rod bushing clearance. Replace the connecting rod if the bushing is so worn that it cannot be reamed or honed for an oversize pin.

On the 240 and 300 Six engines, check the ID of the connecting rod piston pin bore. Replace the connecting rod if the pin bore is not within specifications. Replace defective connecting rod nuts and bolts.

After the connecting rods are assembled to the piston, check the rods for bend or twist on a suitable alignment fixture. Follow the instructions of the fixture manufacturer. If the bend and/or twist exceeds specifications, the rod must be straightened or replaced.

PISTONS, PINS AND RINGS

Remove deposits from the piston surfaces. Clean gum or varnish from the piston skirt, piston pins and rings with solvent. **Do not use a caustic cleaning solution or a wire brush to clean pistons.**

Clean the ring groove with a ring groove cleaner (Fig. 40). Make sure the oil ring slots (or holes) are clean.

Inspection

Carefully inspect the pistons for fractures at the ring lands, skirts, and pin bosses, and for scuffed, rough, or scored skirts. If the lower inner portion of the ring grooves have high steps, replace the piston. The step will interfere with ring operation and cause excessive ring side clearance.

Spongy, eroded areas near the edge of the piston top are usually caused by detonation or pre-ignition. A shiny surface on the thrust surface of the piston, offset from the centerline between the piston pin holes, can be caused by a bent connecting rod. Replace pistons that show signs of excessive wear, wavy ring lands or fractures, or damage from detonation or pre-ignition.

Check the piston to cylinder bore clearance by measuring the piston and bore diameters. Refer to the specifications for the proper clearance. Refer to Cylinder Block Inspection for the bore measurement procedure. **Measure the OD of the piston with micrometers at the centerline of the piston bore and at 90 degrees to the pin bore axis. Check the ring side clearance following the procedure under Fitting Piston Rings in this Section.**

Replace piston pins showing signs of fracture, etching or wear. Check the piston pin fit in the piston and rod. Refer to Pistons and Connecting Rods Assembly, in the pertinent engine Section.

Check the OD of the piston pin and the ID of the pin bore in the piston. Replace any piston pin or piston that is not within specifications.

Replace all rings that are scored,

chipped or cracked. Check the end gap and side clearance. It is good practice to always install new rings when overhauling an engine. Rings should not be transferred from one piston to another regardless of mileage.

MAIN AND CONNECTING ROD BEARING

Cleaning

Clean the bearing inserts and caps thoroughly in solvent, and dry them with compressed air. **Do not scrape gum or varnish deposits from bearing shells.**

Inspection

Inspect each bearing carefully. Bearings that have a scored, chipped, or worn surface should be replaced. Typical examples of bearings that should be replaced and the causes are shown in Fig. 41. The copper-lead bearing base may be visible through the bearing overlay. This does not mean that the bearing is worn. **It is not necessary to replace the bearing if the bearing clearance is within recommended limits.** Check the clearance of bearings that appear to be satisfactory with Plastigage. Fit new bearings following the recommended procedure in this Part.

CYLINDER BLOCK

Cleaning

After any cylinder bore repair operation, such as honing or deglazing, clean the bore(s) with soap or detergent and water. **Then, thoroughly rinse the bore(s) with clean water to remove the soap or detergent, and wipe the bore(s) dry with a clean, lint-free cloth. Finally, wipe the bore(s) with a clean cloth dipped in engine oil. If these procedures are not followed, rusting of the cylinder bore(s) may occur.**

If the engine is disassembled, thoroughly clean the block in solvent. Remove old gasket material from all machined surfaces. Remove all pipe plugs that seal oil passages; then clean out all the passages. Blow out all passages, bolt holes, etc., with compressed air.

Make sure the threads in the cylinder head bolt holes are clean. Dirt in the threads may cause binding and result in a false torque reading. Use a tap to true-up threads and to remove any deposits.

Inspection

After the block has been thoroughly cleaned, check it for cracks. Minute cracks not visible to the naked eye may be detected by coating the suspected area with a mixture of 25 percent kerosene and 75 percent light engine oil. Wipe the part dry and immediately apply a coating of zinc oxide dissolved in wood alcohol. If cracks are present, the coating will become discolored at the cracked area. Replace the block if it is cracked.

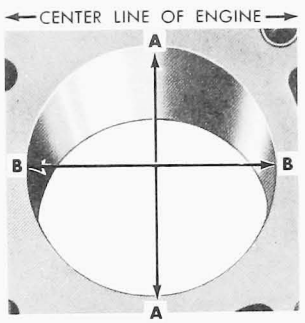

FIG. 42 Cylinder Bore Out-Of-Round and Taper

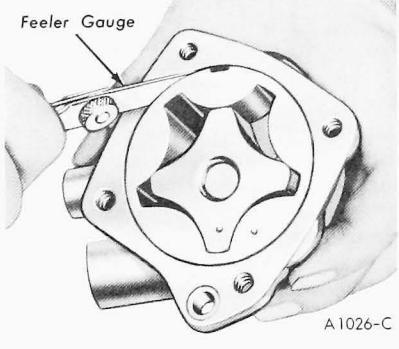

FIG. 43 Checking Outer Race-to-Housing Clearance

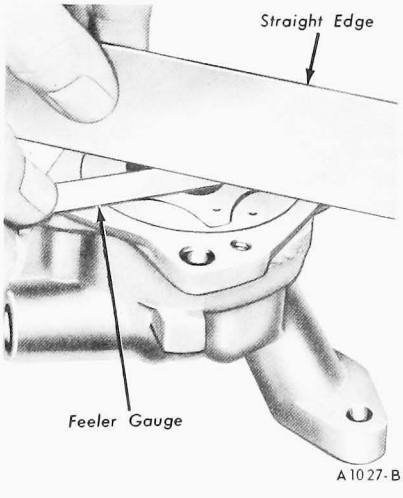

FIG. 44 Checking Rotor End Play

Check all machined gasket surfaces for burrs, nicks, scratches and scores. Remove minor imperfections with an oil stone. Check the cylinder block for flatness of the cylinder head gasket surface following the procedure and specifications recommended for the cylinder head. The cylinder block can be machined to bring the cylinder head gasket surface within the flatness specifications, **but not to exceed 0.010 inch stock removal from the original gasket surface.**

Replace all expansion-type plugs that show evidence of leakage.

Inspect the cylinder walls for scoring, roughness, or other signs of wear. Check the cylinder bore for out-of-round and taper. Measure the bore with an accurate bore gauge following the instructions of the manufacturer. Measure the diameter of each cylinder bore at the top, middle and bottom with the gauge placed at right angles and parallel to the centerline of the engine (Fig. 42). Use only the measurements obtained at 90 degrees to the engine centerline when calculating the piston to cylinder bore clearance.

Refinish cylinders that are deeply scored and/or when out-of-round and/or taper exceed the wear limits.

If the cylinder walls have minor surface damage, but the out-of-round and taper are within limits, it may be possible to remove such damage by honing the cylinder walls and installing new service piston rings providing the piston clearance is within specified limits.

To remove the cylinder wall glaze or to refinish a cylinder bore, follow the honing procedure described under Cylinder Block-Refinishing Cylinder Walls.

OIL PAN

Cleaning

Scrape any dirt or metal particles from the inside of the pan. Scrape all old gasket material from the gasket surface. Wash the pan in a solvent and dry it

thoroughly. Be sure all foreign particles are removed from below the baffle plate.

Inspection

Check the pan for cracks, holes, damaged drain plug threads, and a loose baffle. Check the gasket surface for damage caused by over-torqued bolts. Straighten the surface as required to restore original flatness.

Replace the pan if repairs cannot be made.

OIL COOLER—401, 477 AND 534 V-8

Cleaning

Clean the oil cooler as soon as possible after removing it from the engine, or soak it in cleaning solvent until ready to clean. This will prevent hardening and drying of accumulated foreign material.

Immerse the oil cooler in a commercial cleaning solvent and clean the outside of the plates with a stiff bristle brush.

Pressure circulate a standard commercial solvent (at a pressure of approximately 20 psi) through the oil passages of the cooler in the reverse direction of normal flow. Normal flow is from the bottom hole (inlet) to the top hole (outlet). If a circulating pump is not available, soak the cooler in solvent for a few minutes and force the solvent through the oil passages with a plunger or piston-type hand pump. If the oil passages are severely clogged, use an Oakite or alkaline solution. After cleaning, pressure flush the cooler with clean hot water.

Thoroughly clean the passages in the cover and clean the relief valve assembly. Remove gasket sealer from the cover, oil cooler, and block.

Inspection

The cooler should be checked for leaks under a pressure equivalent to the maximum engine oil pressure.

OIL PUMP

Cleaning

Wash all parts in a solvent and dry them thoroughly with compressed air. Use a brush to clean the inside of the pump housing and the pressure relief valve chamber. Be sure all dirt and metal particles are removed.

Inspection

Refer to the specifications for clearances and wear limits.

Check the inside of the pump housing and the outer race and rotor for damage or excessive wear or scoring.

Check the mating surface of the pump cover for wear. If the cover mating surface is worn, scored or grooved, replace the cover.

Measure the outer race to housing clearance (Fig. 43).

With the rotor assembly installed in the housing, place a straight edge over the rotor assembly and the housing. measure the clearance (rotor end play) between the straight edge and the rotor and outer race (Fig. 44).

The outer race, shaft and rotor are replaceable only as an assembly.

Check the drive shaft to housing bearing clearance by measuring the OD of the shaft and the ID of the housing bearing.

Inspect the relief valve spring for a collapsed or worn condition. Check the relief valve spring tension. If the spring tension is not within specifications and/or the spring is worn or damaged, replace the spring.

Check the relief valve piston for scores and free operation in the bore.

CRANKCASE VENTILATION SYSTEM

Refer to the 1973 Truck Maintenance and Lubrication Manual for the correct mileage interval for maintenance.

Do not attempt to clean the crankcase ventilation regulator valve; replace it at the recommended maintenance interval.

The oil filler tube breather cap, located on the valve rocker arm cover should be cleaned at the proper mileage interval. Remove the cap and wash it in a low-volatility, petroleum base solvent. Shake the cap dry and install it. Do not dry with compressed air as air pressure may damage the filter element.

Clean the crankcase ventilation system connection(s) on the carburetor spacer or intake manifold by probing the inlet nipple with a flexible wire or bottle brush.

Clean the rubber hoses with a low-volatility, petroleum-base solvent and dry with compressed air.

DESCRIPTION

ENGINE

The 240 Six, 300 LD Six and 300 HD Six Engines (Fig. 1), have a displacement of 240 or 300 cubic inches. The compression ratios are as follows: 240 Six-8.5:1, 300 LD and HD Six-8.4:1. The rating plate identification symbol for the 240 Six engine is A. The symbol for the 300 LD and HD Six is B.

An engine identification tag is attached to the engine (refer to Part 21-01).

EXHAUST EMISSION CONTROL SYSTEM

The 1973 engines incorporate an IMCO (improved combustion) exhaust emission control system.

The IMCO exhaust emission control system controls engine combustion at a level to reduce contaminants normally emitted through the exhaust system. This is accomplished by using specially calibrated carburetors and distributors. The EGR (Exhaust Gas Recirculation System) is covered in Volume VI of this manual.

CRANKCASE VENTILATION SYSTEM

Ventilating air enters the crankcase through the oil filler (breather) cap at the rear of the valve rocker arm cover (Fig. 2). The oil filler cap is sealed to prevent air entrance, but the top of the filler cap is connected to the engine air cleaner by a hose to admit clean air to the crankcase. If the system becomes restricted, a backflow condition will occur, thereby venting the crankcase gases into the air cleaner and induction air system.

The amount of regulator valve opening or restriction is governed by intake manifold vacuum pressure (Fig. 3).

FIG. 2 Typical Position Closed-Type Crankcase Ventilation System

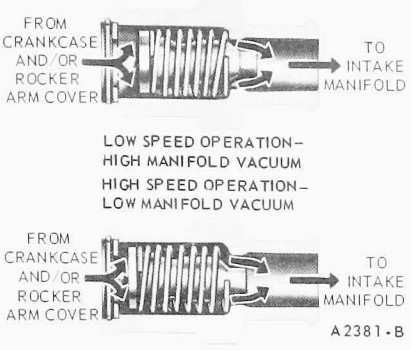

FIG. 3 Positive Closed-Type Crankcase Ventilation Regulator Valve

ADJUSTMENTS

VALVE CLEARANCE

There are two procedures for adjusting the valve clearance on the 240 and 300 Six engines. Both procedures are included in the following paragraphs, but the first procedure is normally used.

PREFERRED PROCEDURE

1. **Install an auxiliary starter switch. Crank the engine with the ignition switch OFF.**
2. Make two chalk marks on the crankshaft damper (Fig. 4). Space the marks approximately 120 degrees apart so that, with the timing mark, the damper is divided into three equal parts (120 degrees is 1/3 of the distance around the damper circumference).
3. Rotate the crankshaft until No. 1 piston is on TDC at the end of the compression stroke. **Check the breakaway torque (torque required to turn nut in a counterclockwise direction)** of each stud nut. Replace the stud nut if the breakaway torque does not meet specifications. If, after replacing the stud nut, the breakaway torque still is not within specifications, replace the stud.
4. With No. 1 piston on TDC at the end of the compression stroke, adjust the intake and exhaust valve clearance for No. 1 cylinder. Loosen the rocker arm stud nut until there is end clearance in the push rod, then tighten the nut to just remove all the push rod to rocker arm clearance. This may be determined by rotating and/or moving the push rod with the fingers as the stud nut is tightened (Fig. 5). When the push rod to rocker arm clearance has been eliminated, tighten the stud nut an additional 1 turn to place the hydraulic lifter plunger in the desired operating range.
5. **Repeat this procedure for the remaining set of valves, turning the crankshaft with an auxiliary starter switch, 1/3 turn at a time, in the direction of rotation, while adjusting the valves in the firing order sequence, 1-5-3-6-2-4.**

   This procedure requires two complete turns of the crankshaft.
6. Operate the engine and check for rough engine idle or a noisy lifter(s). Valve clearance set too tight will cause rough idle and valve clearance set too loose will cause a noisy lifter(s). If it has been determined that these conditions are caused by improper valve clearance, readjust the affected valve(s).

ALTERNATE PROCEDURE

1. Follow steps 1, 2 and 3 in the Preferred Procedure.
2. Position the piston(s) on TDC after the compression stroke (See Step 2 above). Apply pressure to slowly bleed down the valve lifter until the plunger is completely bottomed (Fig. 6). While holding the valve lifter in the fully collapsed position, check the available clearance between the rocker arm and valve stem tip. If the clearance is not within specifications, rotate the rocker arm stud nut clockwise to decrease the clearance and counterclockwise to increase the clearance. **Normally one turn of the rocker arm stud nut will vary the clearance by 0.066 inch.**

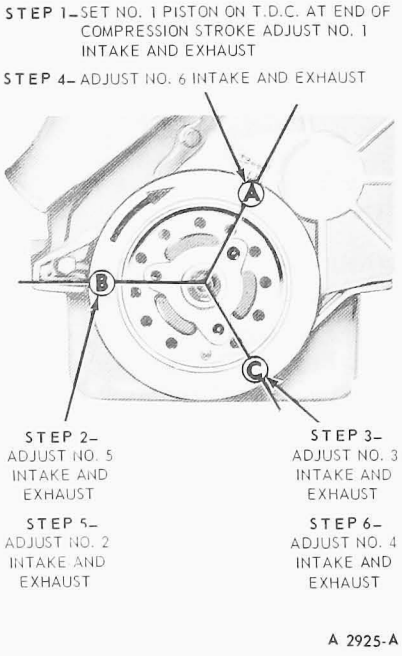

FIG. 4 240 and 300 Six Valve Clearance

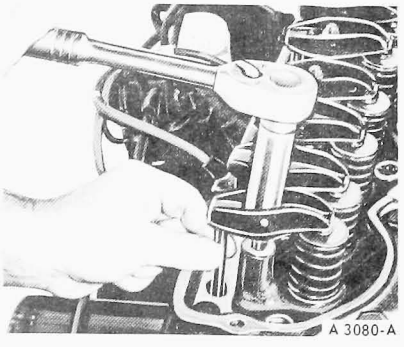

FIG. 5 Valve Clearance Adjustment

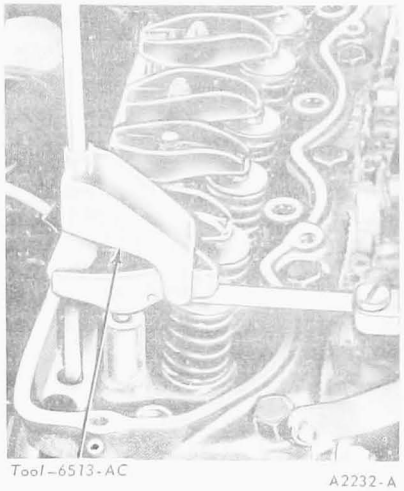

FIG. 6 Valve Clearance Check

REMOVAL AND INSTALLATION

When installing nuts or bolts that must be torqued, oil the threads with light weight engine oil. **Do not oil threads that require oil-resistant or water-resistant sealer.**

Refer to Part 21-01 for Repair and Cleaning and Inspection procedures.

ENGINE ASSEMBLY

ALL EXCEPT ECONOLINE

The engine removal and installation procedures are for the engine only without the transmission attached.

Removal

1. Drain the cooling system and the crankcase. Remove the hood or tilt the cab. Remove the air cleaner. On the C-Series, remove the oil filler tube.
2. Disconnect the battery positive cable. Disconnect the heater hose from the water pump and coolant outlet housing. Disconnect the flexible fuel line from the fuel pump.
3. Remove the radiator following the procedures in Group 27.
4. Remove the cooling fan, water pump pulley and fan drive belt.
5. Disconnect the accelerator cable and the choke cable at the carburetor. Remove the cable retracting spring.

On a vehicle with power brakes, disconnect the vacuum line at the intake manifold.

On a vehicle with an automatic transmission, disconnect the transmission kickdown rod at the bellcrank assembly.

6. Disconnect the exhaust manifold from the muffler inlet pipe. Disconnect the body ground strap and the battery ground cable at the engine.
7. Disconnect the engine wiring harness at the ignition coil, coolant temperature sending unit and oil pressure sending unit. Position the harness out of the way.
8. Remove the alternator mounting bolts and position the alternator out of the way, leaving the wires attached.

On a vehicle with power steering, remove the power steering pump from the mounting brackets and position it right side up and to one side, leaving the lines attached. If equipped with an air compressor, bleed the air system and disconnect the two air pressure lines at the compressor.

9. Raise the vehicle. Remove the starter (and the automatic transmission fluid filler tube bracket). Remove the engine rear plate upper right bolt.

On a vehicle with a manual-shift transmission, remove all the flywheel housing lower attaching bolts. Disconnect the clutch retracting spring.

On a vehicle with an automatic transmission, remove the converter housing access cover assembly. Remove the flywheel to converter nuts and secure the converter assembly in the housing. Remove the transmission oil cooler lines from the retaining clip at the engine. Remove the converter housing to engine lower attaching bolts.

10. On the F-100 and F-250, remove the insulator to intermediate support bracket nut from each engine front support. On other vehicles, remove the engine from support insulator bolt.
11. Lower the vehicle and position a transmission jack under the transmission to support it. Remove the remaining flywheel or converter housing to engine bolts.
12. Attach the engine lifting sling. Raise the engine slightly and carefully pull it from the transmission. Lift the engine out of the chassis.

Installation

1. Place a new gasket on the muffler inlet pipe.
2. Lower the engine carefully into the chassis. Make sure the dowels in the block engage the holes in the flywheel or converter housing.

On a vehicle with an automatic transmission, start the converter pilot into the crankshaft. Remove the retainer securing the converter in the housing.

On a vehicle with a manual-shift transmission, start the transmission input shaft into the clutch disc. It may be necessary to adjust the position of the transmission with relation to the engine if the transmission input shaft will not enter the clutch disc. **If the engine hangs up after the shaft enters, turn the crankshaft slowly (with the transmission in gear) until the shaft splines mesh with the clutch disc splines.**

3. Install the converter or flywheel housing upper attaching bolts. Remove the jack supporting the transmission.
4. Lower the engine until it rests on the engine support(s) and remove the lifting sling.
5. On the F-100 and F-250, install the engine left and right support

insulator to intermediate support bracket attaching nuts. Torque the nuts to specification. Install the front support bolt and nut on other vehicles. Torque to specification. Install the automatic transmission oil cooler lines bracket.

6. Install the remaining converter or flywheel housing attaching bolts. Connect the clutch return spring.
7. Install the starter and connect the starter cable. Attach the automatic transmission fluid filler tube bracket (if so equipped).

On a vehicle with an automatic transmission, install the transmission oil cooler lines in the bracket at the cylinder block.

8. Install the exhaust manifold to muffler inlet pipe lock washers and nuts. Torque the nuts to specifications.
9. Connect the engine ground strap and the battery ground cable.
10. On a vehicle with an automatic transmission, connect the kickdown rod to the bellcrank assembly on the intake manifold.

Connect the accelerator linkage to the carburetor and install the retracting spring. Connect the choke cable to the carburetor and hand throttle if so equipped.

On a vehicle with power brakes, connect the brake vacuum line to the intake manifold. Install the oil filler tube on the C-Series.

11. Connect the coil primary wire, oil pressure and coolant temperature sending unit wires, flexible fuel line, heater hoses and the battery positive cable.
12. Install the alternator on the mounting bracket.

On a vehicle with power steering, install the power steering pump on the mounting brackets.

13. Install the water pump pulley, spacer, cooling fan and drive belt. Torque the fan bolts to specifications.

Adjust all drive belt tension to specifications. Tighten the alternator, power steering pump and air compressor mounting bolts.

14. Install the radiator. Connect the radiator lower hose to the water pump and the radiator upper hose to the coolant outlet housing. Connect the air compressor lines.

On a vehicle with an automatic transmission, connect the oil cooler lines.

15. Install and adjust the hood.
16. Fill and bleed the cooling system. Fill the crankcase. Operate the engine at fast idle and check all hose connections and gaskets for leaks.
17. Adjust the carburetor idle speed and mixture.

On a vehicle with standard transmission, adjust the clutch pedal free travel.

On a vehicle with an automatic transmission, adjust the transmission control linkage. Check the fluid level and add as required to bring it to the proper level.

18. Install the air cleaner.

ECONOLINE

Removal

1. Disconnect the battery. Drain the cooling system.
2. Remove the engine cover. Remove the right hand seat.
3. Remove the hood lock support bracket. Remove the right and left headlight doors and remove the grille.
4. Remove the radiator upper and lower hoses and the transmission oil cooler lines if so equipped.
5. Remove the battery deflector. Remove the radiator.
6. Disconnect the heater hoses at the engine and position out of the way. Disconnect the engine wire harness and position out of the way (temp, oil, coil). Disconnect the wires at the starter solenoid, neutral switch and back-up lights.
7. Remove the engine oil dipstick. Remove the oil filler tube. Disconnect the hoses at the rocker arm cover and air filter and remove the assembly.
8. Remove the air cleaner and brackets as an assembly.
9. Disconnect the choke and accelerator cables at the carburetor.
10. Disconnect the axuiliary heater hose at the front heater. Remove the hoses from the right side of the engine and position them out of the way.
11. Disconnect the fuel line leading from the fuel pump to the carburetor at the fuel pump. Disconnect the wires at the alternator. Remove the alternator from the mounting brackets and position out of the way.
12. Disconnect the ground wires from the cylinder block. Disconnect the muffler inlet pipe from the exhaust manifold.
13. If equipped with automatic transmission, remove the three convertor housing-to-cylinder block upper bolts. Disconnect the starter ground wire.
14. Remove the automatic transmission vacuum line at the manifold if so equipped.
15. Raise the vehicle on the hoist. Drain the crankcase and remove the oil filter.
16. Disconnect the starter cable and remove the starter motor.
17. Position the engine support bar (Fig. 8) to the chassis and engine and adjust.

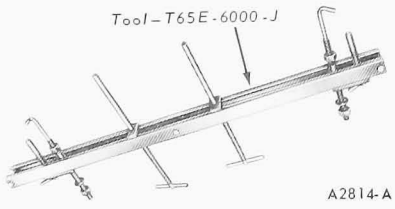

FIG. 8 Econoline Engine Support Bar

18. For vehicles equipped with a manual transmission, disconnect and remove the driveshaft and install a plug in the transmission extension housing. Disconnect the speedometer cable and housing from the transmission and secure it. Remove the bolt and nut attaching the rear engine support to the crossmember. Raise the transmission slightly, remove the crossmember attaching bolts and remove the crossmember. Remove the clutch equalizer arm bracket bolts from the engine. Disconnect the retracting spring and position the assembly out of the way. Remove the transmission to clutch housing bolts and remove the transmission from the vehicle.
19. For vehicles equipped with an automatic transmission, remove the adapter plate and inspection cover to convertor housing bolts. Remove the transmission dipstick tube-to-engine bolt. Remove the dipstick tube from the trans oil pan and drain the transmission. Remove the convertor to flex plate attaching nuts. Disconnect the oil cooler and vacuum lines at the transmission. Disconnect the driveshaft at the companion flange. Disconnect the speedometer cable and housing from the transmission. Disconnect the shift rod at the transmission lever. Position a jack to the transmission and raise the transmission slightly. Remove the nuts and bolts attaching the rear engine mount bracket to the crossmember. Remove the crossmember to side support bolts and nuts and remove the crossmember. Secure the transmission to the jack with safety chain. Remove the remaining transmission to cylinder block bolts. Remove the transmission from the

engine, lower on the jack and roll from under the vehicle.
20. Remove the engine front support insulator attaching nuts. Remove the bellcrank bolt from the side of the cylinder block and position out of the way.
21. Lower the vehicle on the hoist.
22. Remove the fan, spacer and water pump pulley. Position the engine lifting hook to the engine and raise the engine and remove it from the vehicle.
23. Remove the clutch housing from the engine if so equipped.

Installation

1. If so equipped, replace the clutch housing on the engine.
2. Raise the engine and position into vehicle, allowing the engine to rest on the engine front supports and the engine support tool (Fig. 8).
3. Raise the vehicle on the hoist.
4. For vehicles equipped with a manual transmission, raise the transmission, position to the clutch housing and install the attaching bolts. Torque the bolts to specifications. Raise the transmission, position the crossmember to the chassis and rear support and install the attaching bolts. Torque to specifications. Remove the jack. Remove the engine support tool. Connect the shift linkage at the transmission levers. Connect the speedometer cable and housing. Install and connect the drive shaft. Torque the bolts to specifications.
5. Install the engine front support insulator attaching bolts and torque to specifications.
6. Install the transmission bellcrank and torque the bolt in the cylinder block.
7. For automatic transmission equipped vehicles, position the transmission assembly to the cylinder block and install the attaching bolts. Torque to specifications. Position the crossmember to the rear mount bracket and frame sidemembers. Install and torque the attaching bolts and nuts to specifications. Remove the safety chain from the transmission and remove the jack. Remove the engine support bar from the vehicle. Install the convertor to flex plate attaching nuts and torque to specifications. Connect the oil cooler and vacuum lines to the transmission. Install the transmission dipstick and tube in the oil pan. Install the dipstick tube and vacuum line bracket attaching bolt to the cylinder block. Torque to specifications. Connect the driveshaft to the transmission companion flange. Connect the speedometer cable and housing to the transmission. Connect the shift rods to the transmission levers. Install the adapter plate and inspection cover attaching bolts to the convertor housing. Torque to specifications.
8. Install the starter and torque the attaching bolts to specificaions.
9. Connect the muffler inlet pipe at the exhaust manifold.
10. Position the clutch equalizer arm bracket to the transmission (if so equipped). Install and torque the attaching bolts to specifications. Connect the retracting spring.
11. Lower the vehicle on the hoist.
12. Install the remaining automatic transmission-to-cylinder block attaching bolts. Torque to specifications.
13. Install the ground wire and starter motor attaching bolt. Torque to specifications. Connect the starter cable at the starter motor.
14. Install the water pump pulley, spacer and fan assembly. Torque the bolts to specifications.
15. Position and install the alternator to its mounting brackets, install the drive belt and adjust the belt tension.
16. Connect the alternator wires and the back-up light and neutral switch leads.
17. Connect the alternator and battery ground wires to the cylinder block.
18. Connect the automatic transmission vacuum line to the manifold.
19. Connect the fuel line leading from the tank to pump at the fuel pump.
20. Connect the choke and accelerator cables to the carburetor. Install the dipstick tube in the oil pan. Install the tube attaching bolt in the cylinder head and torque to specifications.
21. Connect the neutral and back-up switch wires. Position the engine wire harness and connect the wires (coil, oil, temp.).
22. Connect the auxiliary heater hoses. Connect the oil filler tube to the rocker arm cover and install the retaining clamp. Position the filler tube bracket to the dash panel and install the attaching screws.
23. Install the radiator and battery deflector.
24. Connect the radiator upper and lower hoses and the oil cooler lines (if so equipped).
25. Install the grille in the vehicle. Install the head light doors. Install the hood lock bracket.
26. Fill the crankcase and cooling system. Fill the automatic transmission (if so equipped).
27. Connect the battery cable. Start the engine and check for leaks. Adjust the carburetor idle speed and fuel mixture. If applicable, adjust the automatic transmission linkage.
28. Install the air cleaner and brackets. Install the engine cover. Install the right front seat. Torque the bolts and nuts to specifications.

ENGINE FRONT SUPPORTS

The 240 and 300 CID engines are mounted on three engine mounts. Certain models have one front mount located at the front of the engine and two rear mounts located on each side of the clutch housing. The remaining models have two front mounts located on each side of the engine and one rear mount located on the transmission extension housing.

The mounts and their applications are shown in Figures 9 thru 14.

ECONOLINE

Removal

1. Raise the vehicle on a hoist.
2. Remove the front support insulator to crossmember nuts and washers from both insulators (Fig. 9).
3. Place a transmission jack under the engine oil pan and position a wood block between the jack and oil pan. Raise the engine just enough to take the weight off the crossmember.
4. Remove the insulator assembly to cylinder block bolts and remove the front support insulator(s).

Installation

1. Install the insulator(s) on the cylinder block and torque the bolts to specifications.
2. Lower the engine until the front support insulators engage the crossmember brackets. Remove the transmission jack.
3. Install the front support insulator to crossmember nuts and washers. Torque the nuts to specifications.
4. Lower the hoist.

SINGLE FRONT MOUNT

Removal

1. Remove the bolt that retains the support bracket to the insulators and crossmember (Fig. 10). Remove the washer, lower insulator and spacer.
2. Place a jack under the engine oil pan and position a wood block between the jack and oil pan. Raise the engine just enough to clear the upper insulator. Remove the upper insulator and insulator spacer (LN-600 only).

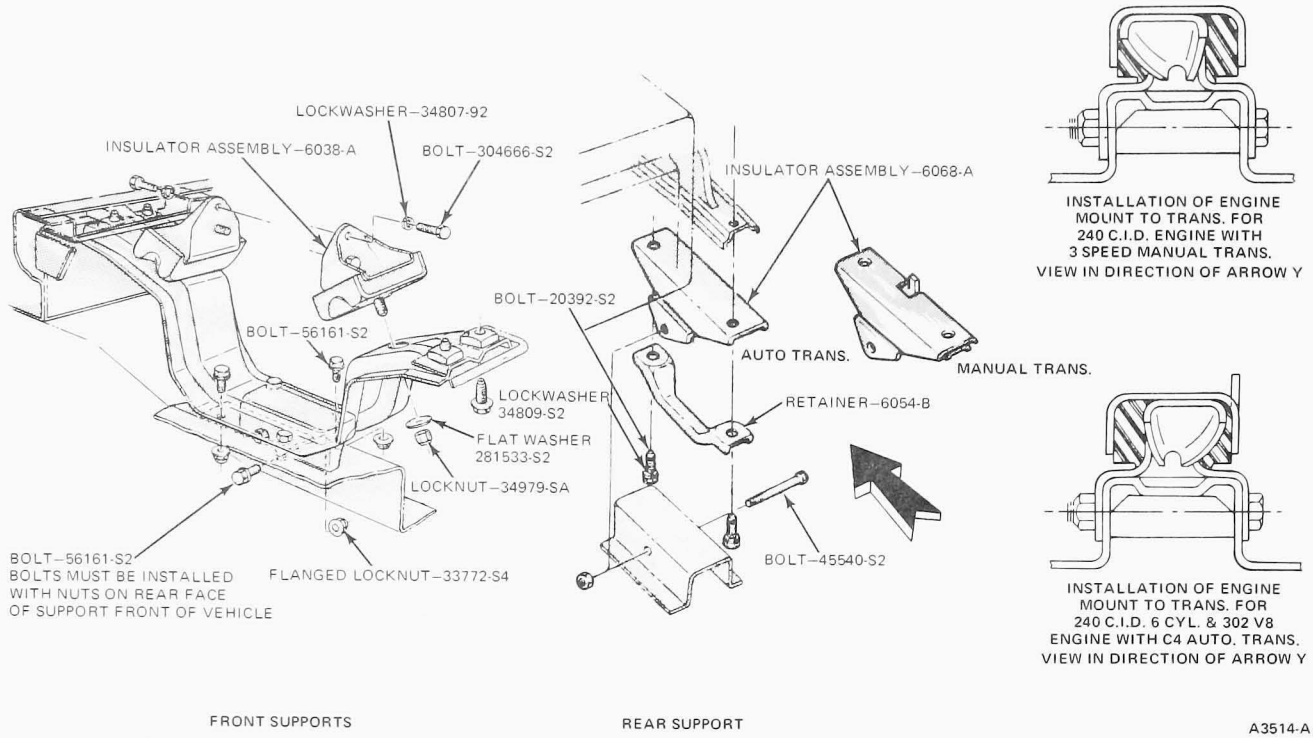

FIG. 9 Econoline Engine Supports

Installation

1. Install the upper insulator spacer (LN-600 only) and the upper insulator (Fig. 10).
2. Position the spacer, lower insulator and washer. Install the attaching nut snugly.
3. Lower the engine and remove the jack and wood block.
4. Torque the attaching nut to specifications.

DOUBLE FRONT MOUNT

The procedures given apply to either a right or left installation (Fig. 11).

Removal

1. Remove the mount to support bracket nut and lock washer. **If only one mount is being removed, loosen the other mount.**
2. Using a jack and a wood block placed under the oil pan, raise the engine to allow just enough clearance for removal of the mount(s).
3. Remove the mount(s) to engine bolts and lock washers. Remove the mount.

Installation

1. Position the mount on the engine. Install the mount-to-engine bolts and lock washers. Torque to specifications.
2. Lower the engine carefully to make sure the mount stud and pin engage the support bracket mounting hole.
3. Install the nut and lock washer on the mount stud. Torque the mount nut and bolts to specifications.

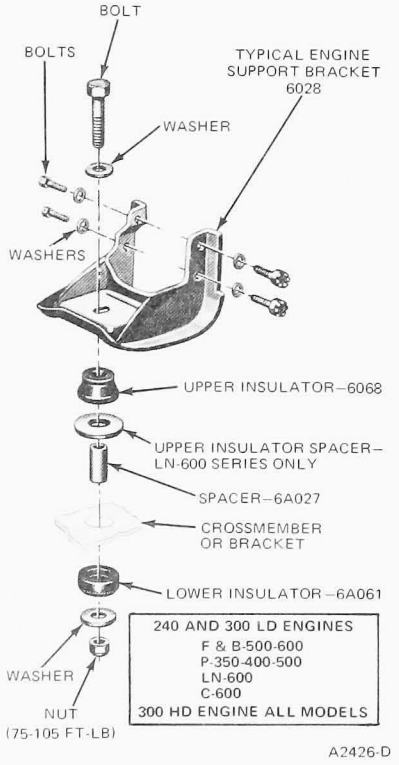

FIG. 10 Engine Single Front Support

4. If only one mount was removed, tighten the other mount.

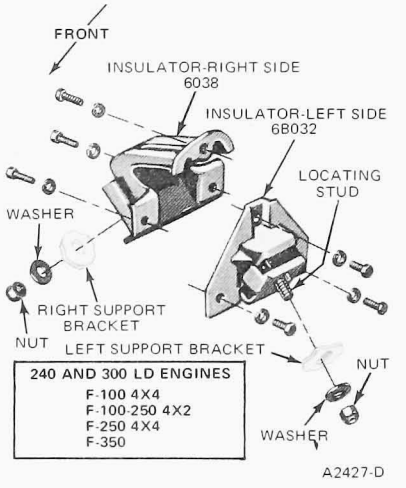

FIG. 11 Engine Double Front Support

ENGINE REAR SUPPORTS

SINGLE REAR MOUNT

Removal

1. Remove the attaching bolts, nut and washers (Fig. 12).
2. Raise the transmission slightly to provide clearance and remove the insulator and insulator retainer.

Installation

1. Position the insulator and retainer (Fig. 12).

The insulator cable is installed two ways. One application has the holes for the insulator-to-extension housing bolts

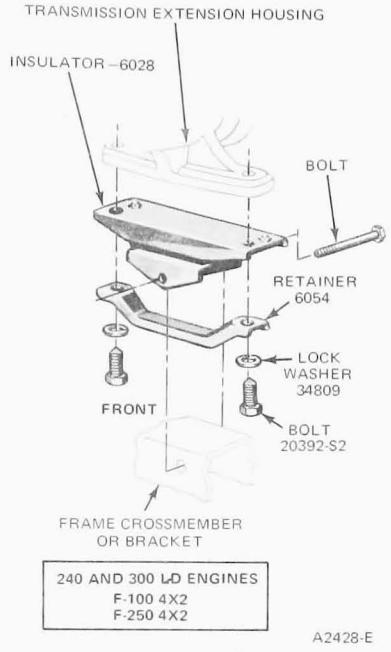

FIG. 12 Engine Single Rear Support

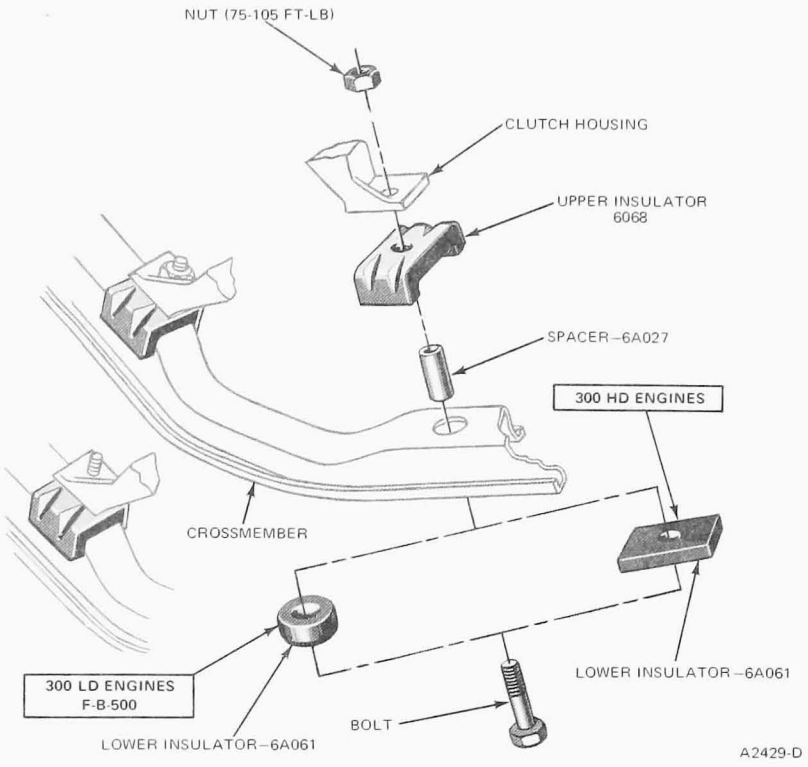

FIG. 13 Engine Double Rear Support

toward the front and is used on the F-100, 250 and 350. The other has the holes off center. It should be placed with the holes towards the front for the 240 Six with a light duty 3-speed manual transmission only. It should be placed with the holes towards the rear for the 240 and 300 LD Six with any transmission other than the light duty.

Install the insulator-to-extension housing, lock washers and bolts.

2. Lower the transmission and install the insulator-to-frame crossmember bolt. Torque the nut and bolts to specifications.

DOUBLE REAR MOUNT

The procedures given apply to either a right or left installation.

Removal

1. Remove the bolt and/or nut attaching the rear support insulator (Figs. 13 and 14). The P-Series trucks have a self-locking bolt. Remove the lower insulator and spacer. **If only one insulator is being removed, loosen the other insulator bolt.**
2. Place a transmission jack under the transmission and raise to clear the upper insulator(s). Remove the upper insulator(s).

Installation

1. Position the upper insulator (Figs. 13 and 14).
2. Install the lower insulator and spacer on the bolt. Position the bolt from the bottom into the crossmember and snug the nut.
3. Lower the engine and remove the jack. Torque the bolt to specifications.

ECONOLINE

Removal

1. Raise the vehicle on a hoist. Place a transmission jack under the transmission and raise it slightly so the transmission weight is not supported by the rear support insulator.
2. Remove the insulator to crossmember and transmission extension housing locknuts and bolts.
3. Remove the rear support insulator.

Installation

1. Position the rear support insulator between the transmission extension housing and vehicle crossmember. **Refer to Fig. 9 for the proper position of the support insulator.**
2. Install the support insulator attaching bolts and locknuts. Torque the locknuts to specifications.
3. Lower the transmission and remove the transmission jack. Lower the vehicle.

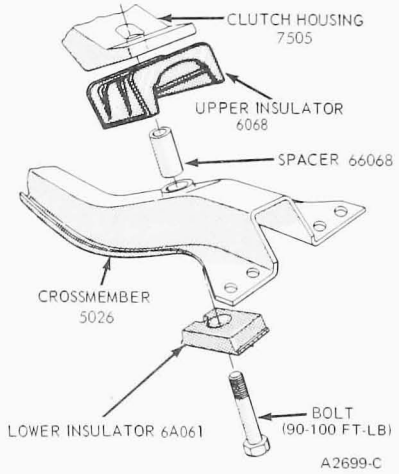

FIG. 14 Engine Double Rear Support—Typical

CRANKCASE VENTILATION SYSTEM

Removal

1. Remove the air cleaner.
2. Grasp the crankcase ventilation regulator valve and pull upwards to remove it from the rocker arm cover.
3. Remove the regulator valve from the vent hose and remove the vent hose from the inlet tube in the intake manifold.
4. Remove the inlet tube from the intake manifold.
5. Remove the air inlet hose from the

oil fill cap and carburetor air cleaner.

Installation

1. Install the inlet tube in the intake manifold.
2. Install the hose on the inlet tube in the intake manifold. Install the regulator valve in the hose.
3. Insert the regulator valve into the rocker arm cover mounting grommet.

Connect the air inlet hose to the oil fill cap and carburetor air cleaner.

4. Install the air cleaner. Operate the engine and check for leaks.

VALVE ROCKER ARM COVER AND ROCKER ARM

Removal

1. Raise the engine compartment cover.
2. Disconnect the inlet air hose at the oil fill cap. Remove the air cleaner.
3. Disconnect the accelerator cable at the carburetor. Remove the cable retracting spring. Remove the accelerator cable bracket from the cylinder head and position the cable and bracket assembly out of the way.
4. Remove the crankcase ventilation regulator valve from the valve rocker arm cover. Remove the cover bolts and remove the valve rocker arm cover.
5. Remove the valve rocker arm stud nut, fulcrum seat and rocker arm.

Inspect the rocker arm cover bolts for defective seals under the bolt heads and replace as necessary. If removal of the rocker arm stud is necessary, refer to the procedure under Cylinder Head Repairs in Part 21-01.

The valve rocker arm assembly is shown in Fig. 15.

Installation

1. Apply Lubriplate or equivalent to the top of the valve stem and at the push rod guide in the cylinder head.
2. Apply Lubriplate or equivalent to the rocker arm fulcrum seat and the fulcrum seat socket in the rocker arm. Install the valve rocker arm, fulcrum seat and stud nut. Adjust the valve clearance following the procedure in this Section under Valve Clearance Adjustment.
3. Clean the valve rocker arm cover and the cylinder head gasket surface. Place the new gasket in the cover making sure that the tabs of the gasket engage the notches provided in the cover.
4. Install the cover on the cylinder head. Make sure the gasket seats evenly all around the head. Partially tighten the cover bolts in sequence, starting at the middle bolts. Then torque the bolts to specifications in the same sequence.
5. Install the crankcase ventilation regulator valve in the rocker arm cover. Install the accelerator cable bracket on the cylinder head and connect the cable to the carburetor.
6. Connect the inlet air hose to the oil fill cap.

MANIFOLDS

Removal

1. Remove the air cleaner. Disconnect the choke cable at the carburetor. Disconnect the accelerator cable or rod at the carburetor. Remove the accelerator retracting spring.
2. On the LN-Series vehicle, disconnect the battery and remove the alternator.
3. On a vehicle with automatic transmission, remove the kick-down rod retracting spring. Remove the accelerator rod bellcrank assembly.
4. On C-Series vehicles, remove the engine oil dipstick and tube.
5. Disconnect the fuel inlet line and the distributor vacuum line from the carburetor.
6. Disconnect the muffler inlet pipe from the exhaust manifold.
7. Disconnect the power brake vacuum line (if so equipped).
8. Remove the bolts and nuts attaching the manifolds to the cylinder head. Lift the manifold assemblies from the engine. Remove and discard the gaskets.
9. To separate the manifolds, remove the nuts joining the intake and exhaust manifolds.

Installation

If the exhaust gas control valve requires replacement, follow the procedures in Part 21-01.

1. Clean the mating surfaces of the cylinder head and manifolds.
2. If one of the manifolds is to be replaced, remove the tube fittings from the discarded manifolds and install them in the new manifold as required. Also install new studs in the new manifold.
3. If the intake and exhaust manifolds have been separated, coat the mating surfaces lightly with graphite grease and place the exhaust manifold over the studs on the intake manifold. Install the lock washers and nuts. Tighten them finger tight.
4. Install a new intake manifold gasket.
5. Coat the mating surfaces lightly with graphite grease. Place the manifold assemblies in position against the cylinder head. **Make sure that the gaskets have not become dislodged. Install the attaching washers, bolts and nuts.** Torque the bolts and nuts to specifications in the sequence shown in Fig. 16.

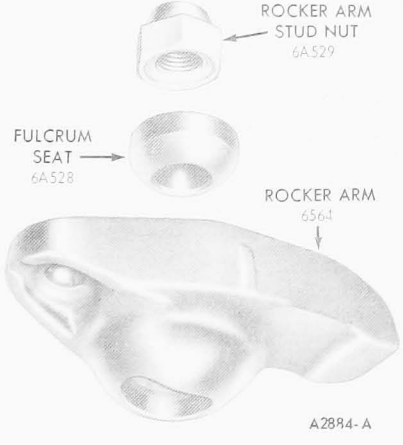

FIG. 15 Valve Rocker Arm Assembly

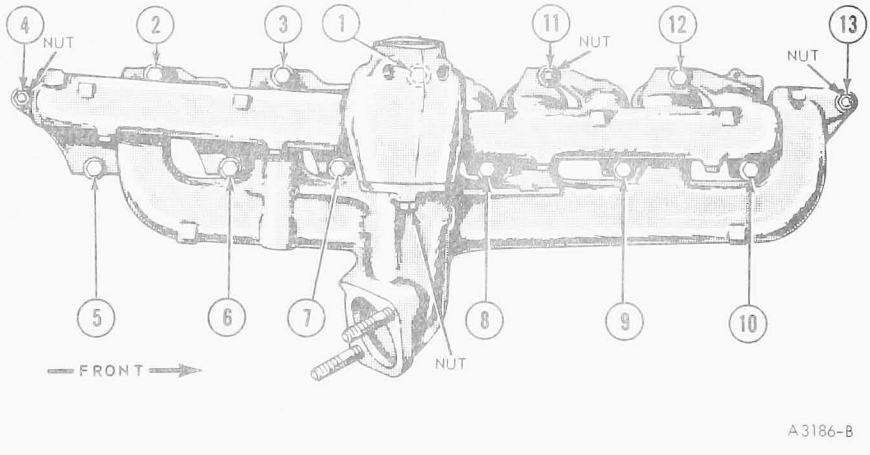

FIG. 16 Intake and Exhaust Manifolds Torque Sequence

If the intake and exhaust manifolds were separated, tighten the nuts joining them.

6. Position a new gasket on the muffler inlet pipe and connect the inlet pipe to the exhaust manifold. Torque the nuts to specifications.
7. Connect the crankcase vent hose to the intake manifold inlet tube and position the hose clamp.
8. Connect the fuel inlet line and the distributor vacuum line to the carburetor.
9. Connect the accelerator cable to the carburetor and install the retracting spring. Connect the choke cable to the carburetor.
10. On the LN-Series, install the alternator and belts and connect the battery.
11. On the C-Series, install the dipstick tube and dipstick.
12. On a vehicle with an automatic transmission, install the bellcrank assembly and kickdown rod retracting spring. Adjust the transmission control linkage.
13. Install the air cleaner. Adjust the engine idle speed and idle fuel mixture.

CYLINDER HEAD

Removal

If the cylinder head is to be replaced, follow the procedures under Cylinder Head Disassembly and Assembly. Transfer all valves, springs, spark plugs, etc., to the new cylinder head. Clean and inspect all parts, reface the valves and check valve guide clearances (refer to Part 21-01) before assembling the used parts to the new cylinder head.

1. Drain the cooling system.
2. Remove the air cleaner.
3. Remove the crankcase ventilation regulator valve from the rocker arm cover. Disconnect the vent hose at the intake manifold inlet tube.
4. Disconnect and remove the carburetor fuel inlet line and the distributor vacuum line.
5. Disconnect the choke cable at the carburetor and position the choke cable and housing out of the way.
6. Remove the accelerator cable retracting spring. Disconnect the accelerator cable from the carburetor.

On a vehicle with an automatic transmission, disconnect the kickdown rod at the carburetor.

7. Disconnect the radiator upper hose and heater hose at the coolant outlet elbow.
8. Disconnect the muffler inlet pipe from the exhaust manifold. Discard the inlet pipe gasket.
9. Remove the coil bracket attaching bolt and position the coil out of the way.
10. Remove the valve rocker arm cover. Loosen the rocker arm stud nuts so that the rocker arms can be rotated to one side.
11. Remove the valve push rods in sequence and identify them so that they can be installed in their original position.
12. Disconnect the spark plug wires at the spark plugs.
13. Remove the cylinder head bolts. Install the cylinder head lifting eyes in the locations shown in Fig. 17. Position a floor crane and attach the hoist and lifting sling to the lifting eyes. Lift the cylinder head and intake and exhaust manifolds assembly off the engine. **Do not pry between the head and block as the gasket surfaces may become damaged.**

Installation

1. Clean the cylinder head and cylinder block gasket surfaces. Clean the exhaust manifold and muffler inlet pipe gasket surfaces.
2. If the cylinder head was removed for a cylinder head gasket replacement, check the flatness of the head and block gasket surfaces (Part 21-01).
3. Position the gasket over the dowel pins on the cylinder block.
4. Install lifting eyes on the cylinder head in the location shown in Fig. 17 and use a floor crane and lifting sling to lift the cylinder head over the cylinder block. Lower it carefully until it is properly positioned on the block and dowel pins. Remove the hoist and lifting eyes.
5. Coat the threads of the cylinder head bolts with engine oil. Install the bolts.
6. Place a new cylinder head gasket on the block. Carefully position the cylinder head on the block and install the bolts. Torque the bolts in sequence (Fig. 17) to specifications. When cylinder head bolts have been tightened it is not necessary to retorque the bolts after extended operation.
7. Apply Lubriplate or equivalent to both ends of the push rods. Install the push rods in their original bores, positioning the lower end of the rods in the valve lifter sockets.
8. Apply Lubriplate or equivalent to the rocker arm fulcrum seat and the fulcrum seat socket in the rocker arm. Position the rocker arms and tighten the stud nuts just enough to hold the push rods in position. Adjust the valve clearance, following the procedure in this section.

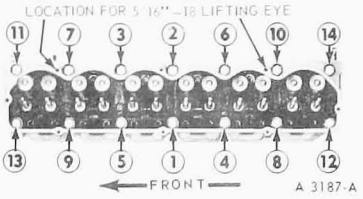

FIG. 17 Cylinder Head Bolts Torque Sequence

9. Clean the valve rocker arm cover. Place the new gasket in the cover making sure that the tabs of the gasket engage the notches provided in the cover. Position the cover, making sure that the gasket seats evenly around the cylinder head. Install the cover bolts and torque in sequence (starting in the center) to specifications.
10. Connect the spark plug wires to the spark plugs.
11. Connect the crankcase vent hose to the inlet tube in the intake manifold. Install the crankcase ventilation regulator valve in the valve rocker arm cover.
12. Position the fuel inlet line and the distributor vacuum line on the engine. Connect the distributor vacuum line to the distributor and carburetor. Connect the carburetor fuel inlet line to the carburetor and fuel pump.
13. Connect the accelerator cable to the carburetor. Install the accelerator cable retracting spring. Connect the choke cable to the carburetor.
14. On a vehicle with an automatic transmission, connect the kickdown rod to the carburetor.
15. Connect the radiator upper hose to the coolant outlet housing. Connect the heater hose to the coolant outlet housing, but do not tighten the clamp.
16. Fill and bleed the cooling system, then tighten the heater hose clamp.
17. Operate the engine until engine temperatures have stabilized. Adjust the engine idle speed and idle fuel mixture. Check for fuel, oil and coolant leaks.
18. Install the air cleaner.

VALVE SPRING, RETAINER AND STEM SEAL

Broken valve springs or defective valve stem seals and retainers may be replaced without removing the cylinder head providing damage to the valve or valve seat has not occurred.

Removal

1. Remove the air cleaner.
2. Remove the accelerator cable retracting spring. Disconnect the accelerator cable at the carburetor. Disconnect the choke cable at the carburetor.
3. Remove the crankcase ventilation regulator valve from the valve rocker arm cover and remove the valve rocker arm cover. Remove the applicable spark plug.
4. Crank the engine until the applicable piston is on TDC after the compression stroke.
5. Install an air line adapter in the spark plug hole (Fig. 18) and connect the air line.
6. Remove the applicable valve rocker arm stud nut, fulcrum seat, valve rocker arm and push rod. Install the stud nut and position the compressor tool as shown in Fig. 18. Compress the valve spring and remove the retainer locks, spring retainer and valve spring. Remove and discard the valve stem seal (Fig. 19).

If air pressure fails to hold the valve in the closed position during this operation, it can be presumed that the valve is not seating or is damaged. If this condition occurs, remove the cylinder head for further inspection.

7. **If air pressure has forced the piston to the bottom of the cylinder, any removal of air pressure will allow the valve to fall into the cylinder. A rubber band, tape or string wrapped around the end of the valve stem will prevent this condition and will still allow enough travel to check the valve for binds.**
8. Inspect the valve stem for damage. Rotate the valve and check the valve stem tip for eccentric movement during rotation. Move the valve up and down through normal travel in the valve guide and check the stem for binds. **If the valve has been damaged, it will be necessary to remove the cylinder head for repairs as outlined in Part 21-01.**
9. If the condition of the valve proved satisfactory, hold the valve in the closed position and apply air pressure within the cylinder.

Installation

1. Oil the valve stem with heavy engine oil and install a new valve stem seal (Fig. 19). Place the spring in position over the valve. **Be sure the closed coil end is next to the cylinder head.** Install the valve spring retainer. Compress the valve spring and install the valve spring retainer locks. Remove the compressor tool and stud nut.
2. Apply Lubriplate or equivalent to both ends of the push rod. Install the push rod. Apply Lubriplate or equivalent to the tip of the valve stem.
3. Apply Lubriplate or equivalent to the fulcrum seat and socket. Install the valve rocker arm, fulcrum seat and stud nut. Adjust the valve clearance following the procedure given in this Part under Valve Clearance Adjustment.
4. Turn off the air and remove the air line and adapter. Install the spark plug and connect the spark plug wire.
5. Clean the valve rocker arm cover. Place the new gasket in the cover making sure that the tabs of the gasket engage the notches provided in the cover. Install the cover, making sure that the gasket seats evenly around the cylinder head. Install the cover bolts and torque them in sequence (starting in the center) to specifications.
6. Connect the accelerator cable to the carburetor. Install the accelerator cable retracting spring. Connect the choke cable to the carburetor.
7. Install the crankcase ventilation regulator valve in the valve rocker arm cover. Install the air cleaner.

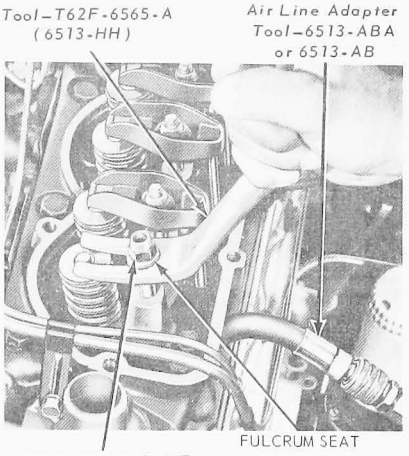

FIG. 18 Compressing Valve Spring—In-Chassis

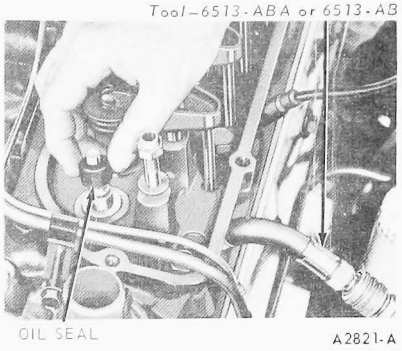

FIG. 19 Removing or Installing Valve Stem Seal

VALVE LIFTER

Removal

1. Remove the air cleaner. Remove the crankcase ventilation regulator valve from the valve rocker arm cover. On the C-Series, disconnect the oil filler tube at the rocker cover.
2. Disconnect the choke cable at the carburetor. Disconnect the accelerator and throttle cable at the carburetor. Remove the retracting spring.
3. Remove the coil bracket attaching bolt and position the coil out of the way.
4. Remove the valve rocker arm cover.
5. Disconnect the spark plug wires at the spark plugs and the secondary high tension wire from the coil. Remove the distributor cap and spark plug wire assembly.
6. Remove the valve push rod cover.
7. Loosen the rocker arm stud nut(s) until the rocker arm(s) can be disengaged from the push rod(s). Remove the push rod(s). Remove the valve lifter(s) with the tool shown in Fig. 20. If more than one push rod and valve lifter is removed,

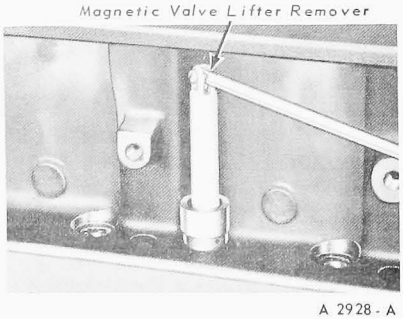

FIG. 20 Removing or Installing Valve Lifter

do it in sequence and place the parts in a rack so they can be installed in their original locations.

Refer to Part 21-01 for the testing procedures.

Installation

1. Clean the rocker arm cover, push rod cover, cylinder head and block gasket surfaces.
2. Apply Lubriplate or equivalent to the cam lobe contact surface of the valve lifter(s). Coat the rest of the valve lifter(s) with engine oil. Install the valve lifters with the tool shown in Fig. 20.
3. Apply Lubriplate or equivalent to both ends of the push rod(s). Install the push rod(s) in sequence. Engage the rocker arm(s) with push rod(s) and tighten the rocker arm stud nut(s) sufficiently to hold the push rod(s) in place. **Be sure each push rod is properly seated in the valve lifter socket.**
4. Adjust the valve clearance, following the procedure given in this Part.
5. Coat one side of a new push rod cover gasket with oil-resistant sealer and position the gasket, cemented side toward the push rod. Install the push rod cover. Torque the cover screws in sequence to specifications. Clean the rocker arm cover. Place the new gasket in the cover making sure that the tabs of the gasket engage the notches provided in the rocker arm cover. Install the cover and torque the bolts to specification. Install the crankcase regulator valve in the rocker arm cover. Connect the oil filler on the C-Series.
6. Position the coil on the cylinder head and install the attaching bolt.
7. Install the distributor cap and spark plug wire assembly. Connect the spark plug wires and coil secondary high tension wire.
8. Connect the accelerator cable and throttle cable to the carburetor. Install the cable retracting spring. Connect the choke cable to the carburetor.
9. Install the air cleaner. Start the engine and adjust the carburetor idle speed and fuel mixture.

WATER PUMP

Removal

1. Drain the cooling system. Loosen the alternator adjusting arm bolt and remove the alternator drive belt. On a vehicle with an air compressor, remove the compressor belt.
2. Remove the fan and pulley.
3. Disconnect the heater hose, radiator lower hose and radiator supply line at the water pump.
4. Remove the bolts attaching the water pump to the block. Remove the pump and gasket.

Installation

Before a water pump is re-installed, check it for damage. If it is damaged and requires repair, replace it with a new pump or install a rebuilt pump obtained from a Ford-Authorized Reconditioner.

1. If a new water pump is to be installed, remove the fittings from the old pump and install them on the new pump. Clean all gasket material from the mounting surfaces of the water pump and cylinder block.
2. Position a new gasket, coated on both sides with sealer, on the water pump.
3. Install the pump body on the block. Install the pump attaching bolts, coated with sealer and torque the bolts to specifications.
4. Connect the radiator lower hose, radiator supply line and heater hose. Install the pulley and fan. Install the alternator belt and adjust the belt tension. On a vehicle with an air compressor, install the air compressor belt and adjust the belt tension to specifications. Fill and bleed the cooling system. Operate the engine and check for leaks.

CYLINDER FRONT COVER AND FRONT OIL SEAL

Removal

1. Drain the cooling system and crankcase.
2. Remove the radiator.
3. Remove the alternator adjusting arm bolt, loosen the drive belt and swing the adjusting arm out of the way. Remove the fan, drive belts and pulley. It may be necessary to remove the air compressor belt and/or steering pump belt.
4. Remove the cam screw and washer from the end of the crankshaft and remove the damper (Fig. 21).
5. Remove the oil level dipstick. Remove the oil pan and related parts by following the procedure under Oil Pan Removal. Remove the oil pump screen and inlet tube assembly.
6. Remove the cylinder front cover and discard the gasket. It is good practice to replace the oil seal each time the cylinder front cover is removed.
7. Drive out the old seal with a pin punch. Clean out the recess in the cover.

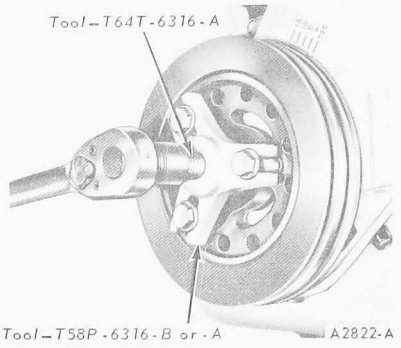

FIG. 21 Removing Crankshaft Damper

Installation

1. Coat a new seal with grease and install the seal (Fig. 22). Drive the seal in until it is fully seated in the recess. After installation, check to be sure the seal is properly positioned in the cover and the spring is properly positioned in the seal.
2. Clean the cylinder front cover and the gasket surfaces of the cylinder block. Coat the gasket surface of the block and cover with oil-resistant sealer. Position a new gasket on the block.

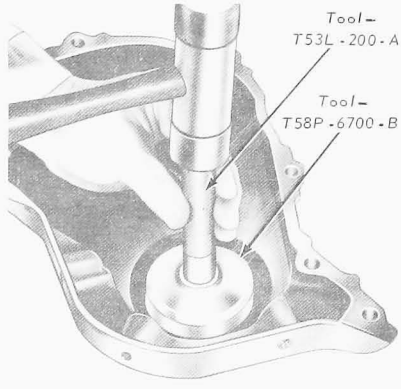

FIG. 22 Installing Crankshaft Front Oil Seal

3. Insert the small diameter end of the cover alignment tool in the bore of the cover. Position the cover and pilot assembly over the end of the crankshaft and against the block (Fig. 23), being careful to align the cover flush with the cylinder block oil pan gasket surface. Install the alternator adjusting arm and cylinder front cover bolts. Torque all the bolts except the power steering pump bracket bolts (if so equipped) to specifications.

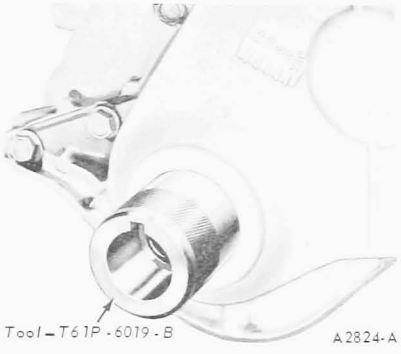

FIG. 23 Aligning Cylinder Front Cover

4. Lubricate the crankshaft with a white lead and oil mixture to facilitate installation and removal of the damper. Lubricate the front oil seal rubbing surface on the damper inner hub and the inner surface (sealing area) of the oil seal with Lubriplate or equivalent.
5. Align the damper keyway with the key on the crankshaft. Install the damper on the crankshaft as shown in Fig. 24.
6. Install the washer and cap screw. Torque the cap screw to specifications.

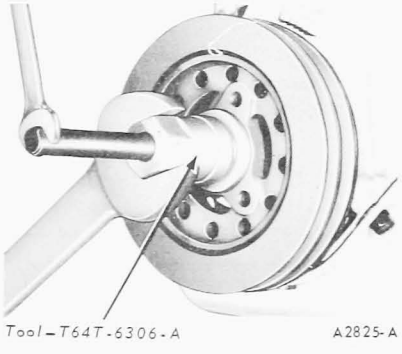

FIG. 24 Installing Damper

7. Apply oil-resistant sealer to the cavities between the rear main bearing cap and cylinder block (Fig. 25). Install a new oil pan rear seal in the rear main bearing cap and apply a bead of oil-resistant sealer to the tapered ends of the seal.
8. Install new side gaskets on the oil pan with oil-resistant sealer (Fig. 21). Position a new cylinder front cover seal on the oil pan.
9. Clean and install the oil pump screen and inlet tube assembly. Install the oil pan and related parts following the procedure under Oil Pan Installation. Install the oil level dipstick.
10. Install the water pump pulley, drive belts and fan. Adjust all drive belt tensions to specifications. Install the radiator.
11. Fill and bleed the cooling system. Fill the crankcase.
12. Operate the engine at fast idle and check all hose connections and gaskets for leaks.

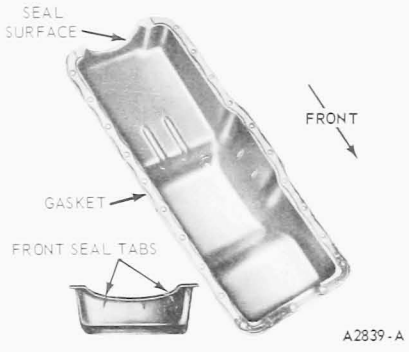

FIG. 25 Oil Pan Gaskets and Front Seal Installed

CAMSHAFT

The camshaft and related parts are shown in Fig. 26.

Removal

1. Drain the cooling system and the crankcase.
2. Remove the air cleaner. Remove the crankcase ventilation regulator valve from the rocker arm cover.
3. Disconnect the accelerator cable at the carburetor. Remove the accelerator cable retracting spring. Disconnect the choke cable at the carburetor. If equipped with a hand throttle cable, disconnect at the carburetor and position out of the way.
4. Remove the radiator. Remove the engine oil dipstick and tube on the C-Series truck and disconnect the oil filler hose from the rocker cover.
5. Remove the power steering belt. Remove the air compressor belt.
6. Loosen the alternator adjusting arm bolt and remove the drive belt and water pump pulley.
7. Disconnect the spark plug wires at the spark plugs and disconnect the secondary high tension wire at the ignition coil. Remove the distributor cap and spark plug wires as an assembly.
8. Disconnect the fuel outlet lines at the fuel pump. Remove the fuel pump mounting bolts and position the fuel pump out of the way.
9. Disconnect the vacuum line at the distributor and the primary wire at the coil. Remove the distributor.
10. Remove the valve rocker arm cover. Loosen the rocker arm stud nuts, move the rocker arms to one side and remove the push rods in sequence. Place the push rods in a rack so they can be installed in their original locations.
11. Remove the valve push rod cover; then remove the valve lifters in sequence, using the tool shown in Fig. 29. Place the valve lifters in a tray or rack to facilitate installation in the same sequence in which they were removed.
12. Remove the cap screw and washer from the end of the crankshaft. Remove the damper (Fig. 21).
13. Remove the oil pan and related parts by following the procedure under Oil Pan Removal. Remove the oil pump screen and inlet tube assembly.
14. Remove the cylinder front cover and discard the gasket.
15. Check the camshaft end play, the timing gear backlash and the timing gear runout (Part 21-01).
16. Turn the crankshaft to align the timing marks as shown in Fig. 27.
17. Remove the camshaft thrust plate screws (Fig. 28). Remove the camshaft. **Avoid damaging the camshaft lobes during removal.** Press the camshaft out of the gear in an Arbor Press (Fig. 29). Remove the key, thrust plate and spacer.

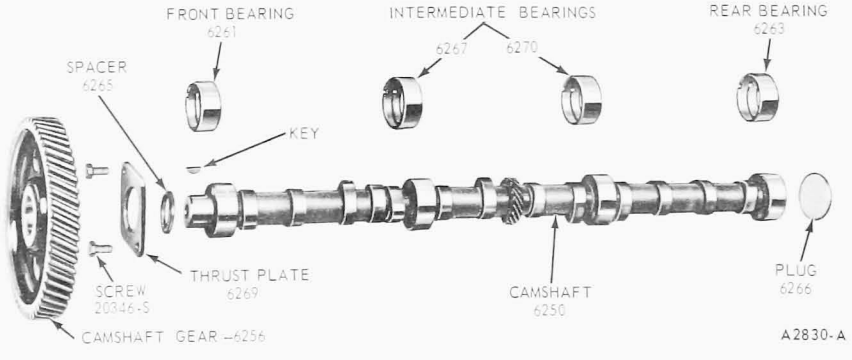

FIG. 26 Camshaft and Related Parts

FIG. 27 Aligning Timing Marks

Installation

If the camshaft end play, timing gear backlash and/or timing gear runout were excessive, make the necessary corrections before installing the camshaft.

1. Oil the camshaft bearing journals and apply Lubriplate or equivalent to all the lobes.
2. Install the camshaft, gear and thrust plate as an assembly, making sure that the timing marks are in alignment (Fig. 27).
3. Torque the thrust plate attaching screws to specifications.
4. Position the camshaft gear on the camshaft. Align the timing marks on the timing gears as shown in Fig. 27. Install the camshaft gear with the tool shown in Fig. 30. Be sure the gear and spacer are tight against the shoulder on the camshaft.
5. Crank the engine until the timing marks are aligned. **Do not turn the crankshaft again until the distributor is installed.**
6. Clean the cylinder front cover and cylinder block gasket surfaces. Install a new oil seal in the cylinder front cover. **Clean the crankshaft damper and inspect it, following the procedures in Part 21-01.** Install the cylinder front cover and damper, following the applicable procedure under Cylinder Front Cover Installation.
7. Clean the oil pump screen. Clean the oil pan and the gasket surfaces of the cylinder block. Install the oil pump screen and inlet tube and oil pan, following the procedures under Oil Pan Installation.
8. Lubricate the valve lifters with heavy engine oil and install the lifters (Fig. 20) in the same bores from which they were removed. Apply Lubriplate or equivalent to both ends of the push rods and install the push rods in the same sequence that they were removed. Be sure the push rods were seated in the valve lifter sockets.
9. Clean the valve push rod cover and cylinder block gasket surfaces. Apply oil-resistant sealer to one side of a new gasket and place the gasket on the push rod cover with the cemented side next to the cover. Install the cover and torque the bolts in sequence to specifications.
10. Apply Lubriplate or equivalent to the valve pad on the rocker arms. Oil the valve stems with heavy engine oil. Align the valve rocker arms with the valves and push rods. Tighten the rocker arm stud nuts sufficiently to hold the push rods in place. Adjust the valve clearance following instructions given in this Part under Valve Clearance Adjustment.
11. Clean the valve rocker arm cover and cylinder head gasket surface. Place the new gasket in the cover making sure that the tabs of the gasket engage the notches provided in the cover. Install the cover and torque the screws in sequence to specifications.
12. Set the distributor rotor so the points are about to open for No. 1 cylinder firing position. Install the distributor. Check the points. If the camshaft timing marks are still aligned (step 6 above), the points should be fully open in No. 1 cylinder firing position. If the points are not open, remove the dsitributor and rotate the shaft in the proper direction. Install the distributor and hold-down clamp.
13. Clean the fuel pump and cylinder block gasket surfaces. Install the fuel pump with a new gasket. Torque the mounting bolts to specifications. Connect the fuel outlet line to the fuel pump.
14. Install the distributor cap and spark plug wires as an assembly. Connect the spark plug wires to the plugs and the secondary high tension wire to the coil.
15. Install the crankcase ventilation regulator valve in the valve rocker arm cover. Connect the oil filler hose to the rocker cover on the C-Series. Install the accelerator cable housing bracket on the cylinder head. Connect the accelerator cable to the carburetor. Install the accelerator cable retracting spring. Connect the choke cable and, if so equipped, the hand throttle cable.
16. Install the water pump pulley, cooling fan and drive belt. Adjust the belt tension to specifications. Install the air compressor belt following procedures in Group 12. Install the power steering belt following procedures in Group 13.
17. Install the radiator. Connect the radiator upper hose to the thermostat housing cover. Connect the lower hose to the water pump. Install the hood latch support bracket. Install the radiator grille assembly.
18. Install the air cleaner.
19. Fill the crankcase and cooling system.
20. Start the engine and check for oil, coolant and fuel leaks. Adjust the ignition timing. Connect the distributor vacuum line to the distributor. Adjust the carburetor idle speed and fuel mixture.

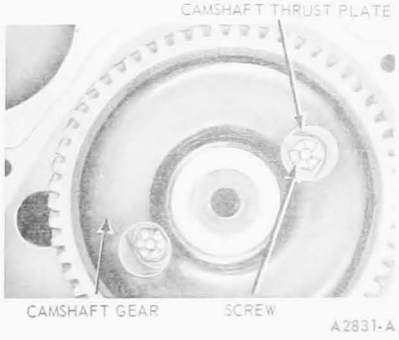

FIG. 28 Removing or Installing Camshaft

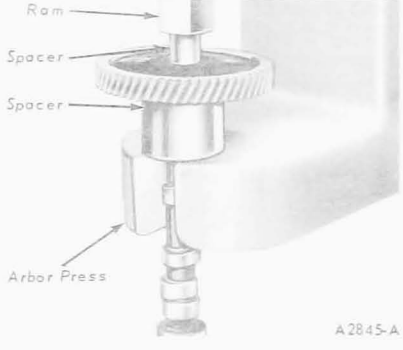

FIG. 29 Removing Fiber Camshaft Gear

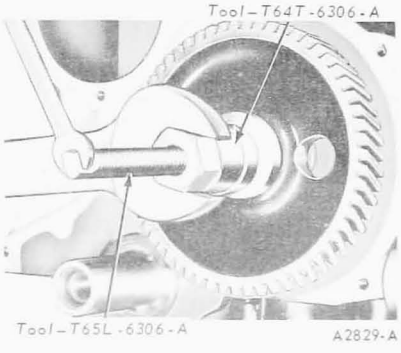

FIG. 30 Installing Camshaft Gear

TIMING GEARS

The engine has a gear driven camshaft. When the crankshaft and camshaft lose their timing relationship through the removal of the timing gears, interference may occur between the crankshaft and cam lobes. **Therefore, to prevent possible damage to the camshaft lobes, do not rotate the camshaft or crankshaft in the engine without the timing gears installed.**

CAMSHAFT GEAR—METAL GEAR

Removal

1. Drain the cooling system and crankcase.
2. Remove the cylinder front cover and oil pan, following the procedures under Cylinder Front Cover Removal.
3. Check the camshaft end play, the timing gear backlash and the timing gear runout (Part 21-01).
4. Crank the engine until the timing marks are aligned as shown in Fig. 27.
5. Install the gear puller as shown in Fig. 31 and remove the camshaft gear.

Installation

If the camshaft end play, timing gear backlash and/or timing gear runout were excessive, make the necessary corrections before installing the gear.

1. Be sure the key and spacer are properly installed. Align the gear keyway with the key and install the gear on the camshaft as shown in Fig. 30. Be sure that the timing marks line up on the camshaft and crankshaft gears.
2. Install the cylinder front cover and related parts, following the procedures under Cylinder Front Cover Installation.
3. Fill the crankcase and cooling system. Start the engine and adjust the ignition timing. Operate the engine at fast idle and check all hose connections and gaskets for leaks.

CAMSHAFT GEAR—FIBER GEAR

Removal

1. Drain the cooling system and crankcase.
2. Remove the radiator following procedures in Group 27.
3. Remove the cylinder front cover following the procedures under Camshaft Removal.
4. Check the camshaft end play, the timing gear backlash and the timing gear runout (Part 21-01).
5. Remove the camshaft, following the procedures under Camshaft Removal. Press the camshaft gear off the camshaft in an Arbor Press

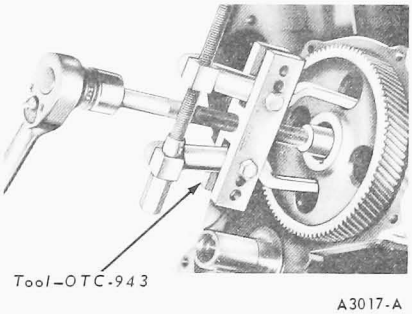

FIG. 31 Removing Metal Camshaft Gear

(Fig. 29). Remove the thrust plate, spacer and key.

Installation

If the camshaft end play, timing gear backlash and/or timing gear runout were excessive, make the necessary corrections before installing the gear.

1. Install the camshaft in the engine and install the spacer and thrust plate on the camshaft. Insert the key in the keyway. Position the camshaft gear on the camshaft with the timing marks aligned (Fig. 22) and install it as shown in Fig. 24. **Be sure the gear and spacer are tight against the shoulder on the camshaft and that the thrust plate can be moved freely.** Install the thrust plate screws and torque to specifications.
2. Install the cylinder front cover, oil pan and related parts, following the procedures under Camshaft Installation.
3. Install the radiator.
4. Fill the crankcase and the cooling systems. Start the engine and adjust the ignition timing. Operate the engine at fast idle and check all hose connections and gaskets for leaks.

CRANKSHAFT GEAR

Removal

1. Drain the cooling system and crankcase. Remove the radiator, following the procedure in Group 27.
2. Remove the cylinder front cover.
3. Remove the oil slinger from the crankshaft. Use the gear puller as shown in Fig. 32 and remove the crankshaft gear. Remove the key from the crankshaft.

Installation

1. Install the key in the crankshaft keyway. Install the crankshaft gear, using the tool shown in Fig. 33. Install the oil slinger.
2. Replace the crankshaft front oil seal and install the cylinder front cover, following the procedures under Cylinder Front Cover.
3. Install the radiator.
4. Fill the crankcase and the cooling systems. Start the engine and check all gaskets and hose connections for leaks. Adjust the ignition timing.

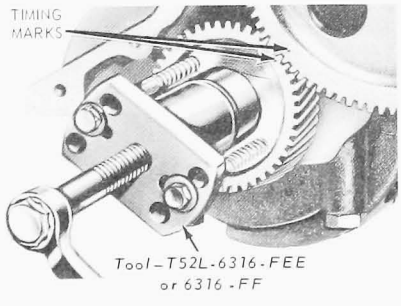

FIG. 32 Removing Crankshaft Gear

FLYWHEEL

Removal

1. Remove the transmission, following the procedure in Group 16 (Clutch and Manual Transmission) or Group 17 (Automatic Transmission).
2. On a manual-shift transmission, remove the clutch pressure plate and cover assembly and clutch disc, following the procedure in Group 16.
3. Remove the flywheel attaching bolts and remove the flywheel.

To check flywheel face runout or replace the flywheel ring gear, refer to Part 21-01.

Installation

1. Position the flywheel on the crankshaft flange. Coat the threads of the flywheel attaching bolts with oil-resistant sealer and install the bolts. Torque the bolts in sequence across from each other to specifications.
2. On a manual-shift transmission, install the clutch disc and the pressure plate and cover assembly following the procedure in Group 16.

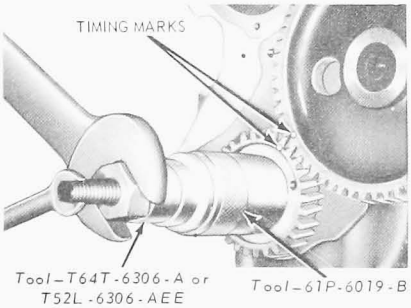

FIG. 33 Installing Crankshaft Gear

3. Install the transmission following the procedure in Group 16 or Group 17.

CLUTCH PILOT BUSHING

Inspection procedures are outlined under Crankshaft Cleaning and Inspection in Part 21-01.

Removal

1. Remove the transmission from the engine, following the procedure in Group 16.
2. Remove the pressure plate and cover assembly and clutch disc following the procedure in Group 16.
3. Remove the clutch pilot bushing (Fig. 34).
4. Wipe any lubricant from the pilot bushing bore. It is not necessary to lubricate the new bushing or transmission input shaft.

Installation

1. Install the clutch pilot service bushing (Fig. 35).
2. Install the clutch disc and the pressure plate assembly following the procedure in Group 16.
3. Install the transmission, following the procedure in Group 16.

CAMSHAFT REAR BEARING BORE PLUG

Removal

1. Remove the transmission and flywheel housing, following the procedures in Group 16 (Manual Transmission) or Group 17 (Automatic Transmission). On a manual-shift transmission, remove the clutch pressure plate and disc following the procedures in Group 16.
2. Remove the flywheel attaching bolts. Remove the flywheel and the engine rear cover plate.

Installation

1. Replace the core plug as detailed in Part 21-01.

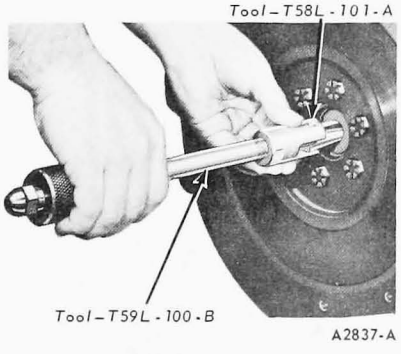

FIG. 34 Removing Clutch Pilot Bushing

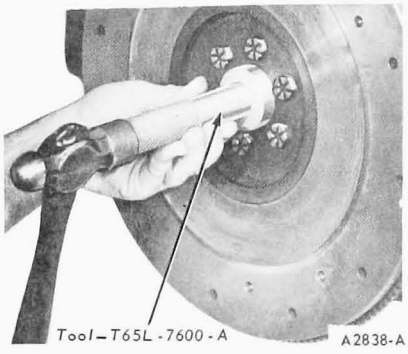

FIG. 35 Installing Clutch Pilot Bushing

2. Install the engine rear cover plate and flywheel. Coat the flywheel attaching bolts with oil-resistant sealer and install the bolts snug. Torque the flywheel bolts in sequence to specifications. On a vehicle with a manual-shift transmission, install the clutch pressure plate and disc and transmission, following the procedure in Group 16. On a vehicle with an automatic transmission, install the transmission and converter housing following the procedure in Group 17.

OIL PAN

Removal

1. Drain the crankcase.
   On the F-100-250, also drain the cooling system.
2. Remove the radiator from the F-100-250 following procedures in Group 27.
3. Raise the vehicle on a hoist.
   Disconnect the starter cable at the starter on the F-100-250 and remove the attaching bolts and starter.
4. On the F-100-250, remove the engine front support insulator to support bracket nuts and washers on both supports. Raise the front of the engine with a transmission jack and wood block and place 1-inch thick wood blocks between the front support insulators and support brackets. Lower the engine and remove the transmission jack.
5. Remove the oil pan attaching bolts. Remove the oil pump inlet tube attaching bolts. Remove the inlet tube and screen assembly from the oil pump and leave it in the bottom of the oil pan. Remove the oil pan and gaskets. Remove the inlet tube and screen from the oil pan.

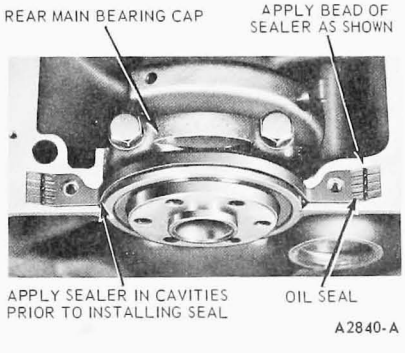

FIG. 36 Installing Oil Pan Rear Seal

Installation

1. Clean the gasket surfaces of the oil pump, oil pan and cylinder block. Remove the rear main bearing cap to oil pan seal and cylinder front cover to oil pan seal. Clean the seal grooves.
2. Apply oil-resistant sealer in the cavities between the bearing cap and cylinder block (Fig. 36). Install a new seal in the rear main bearing cap and apply a bead of oil-resistant sealer to the tapered ends of the seal.
3. Install new side gaskets on the oil pan with oil-resistant sealer (Fig. 25). Position a new oil pan to cylinder front cover seal on the oil pan.
4. Clean the inlet tube and screen assembly and place it in the oil pan.
5. Position the oil pan under the engine. Install the inlet tube and screen assembly on the oil pump with a new gasket. Torque the screws to specifications. Position the oil pan against the cylinder block and install the attaching bolts. Torque the bolts in sequence to specifications.
6. Raise the F-100-250 engine with a transmission jack and remove the wood blocks from the engine front supports. Lower the engine until the front support insulators are

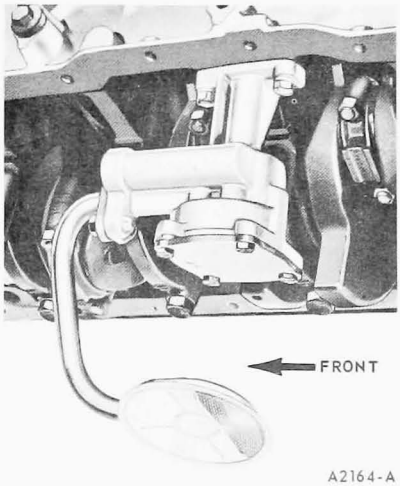

FIG. 37 Oil Pump Installed

positioned on the support brackets. Install the washers and nuts on the insulator studs and torque the nuts to specifications.
7. Install the starter on the F-100-250 and connect the starter cable.
8. Lower the vehicle. Install the radiator following procedures in Group 27.
9. Fill the crankcase and cooling system.
10. Start the engine and check for coolant and oil leaks.

OIL PUMP

Removal
1. Remove the oil pan following the procedures under Oil Pan Removal.
2. Remove the oil pump attaching bolts (Fig. 37). Discard the gasket.

Installation
1. Prime the oil pump by filling the inlet opening with oil and rotate the pump shaft until oil emerges from the outlet opening.
2. Coat a new oil pump gasket with oil-resistant sealer and position it on the oil pump.
3. Install the oil pump on the cylinder block. Torque the attaching bolts to specifications.

CRANKSHAFT REAR OIL SEAL

If the crankshaft rear oil seal replacement is the only operation being performed, it can be done in the vehicle as detailed in the following procedure. **If the oil seal is being replaced in conjunction with a rear main bearing replacement, the engine must be removed from the vehicle and installed on a work stand (Fig. 38).**

Removal
1. Remove the starter.
2. Remove the transmission from the vehicle, following the procedures in Group 16 (manual-shift transmission) or Group 17 (Automatic transmission).
3. On a manual-shift transmission remove the pressure plate and cover assembly and the clutch disc following the procedure in Group 16.
4. Remove the flywheel attaching bolts and remove the flywheel and engine rear cover plate.
5. Use an awl to punch two holes in the crankshaft rear oil seal. Punch the holes on opposite sides of the crankshaft and just above the bearing cap to cylinder block split line. Install a sheet metal screw in each hole. Use two large screwdrivers or small pry bars and pry against both screws at the same time to remove the crankshaft rear oil seal. It may be necessary to place small blocks of wood against the cylinder block to provide a fulcrum point for the pry bars. **Use caution throughout this procedure to avoid scratching or otherwise damaging the crankshaft oil seal surface.**
6. Clean the oil seal recess in the cylinder block and main bearing cap.

Installation
1. **Clean, inspect and polish the rear oil seal rubbing surface on the crankshaft, following the procedures in Part 21-01.** Coat a new oil seal and the crankshaft with a light film of engine oil. Start the seal in the recess and install it with the tool as shown in Fig. 39. Keep the tool straight with the centerline of the crankshaft and install the seal until the tool contacts the cylinder block surface. **Remove the tool and inspect the seal to be sure it was not damaged during installation.**
2. Install the engine rear cover plate. Position the flywheel on the crankshaft flange. **Coat the threads of the flywheel attaching bolts with oil-resistant sealer and install the bolts. Torque the bolts in sequence across from each other to specifications.**
3. On a manual-shift transmission, install the clutch disc and the pressure plate assembly following the procedure in Group 16.
4. Install the transmission, following the procedure in Group 16 (manual-shift transmission), or Group 17 (automatic transmission). **Do not adjust the transmission linkage.**

MAIN BEARING

Do not file or lap bearing caps or use shims to obtain the proper bearing clearance.

Bearings are available for service in standard sizes or 0.001 and 0.002 inch undersize. Refer to the Parts Catalog for the available sizes. Undersize bearings are available for use on journals that have been refinished.

If the rear main bearing is to be replaced, it will be necessary to remove the engine, install it on a work stand, replace the main bearing and replace the crankshaft rear oil seal.

Removal
1. Drain the crankcase. Remove the oil pan and oil pump, following the procedure under Oil Pan Removal.
2. **Replace one bearing at a time, leaving the other bearings securely fastened.** Remove the main bearing cap to which new bearings are to be installed.
3. Insert the upper bearing remover (tool 6331) in the oil hole in the crankshaft journal.

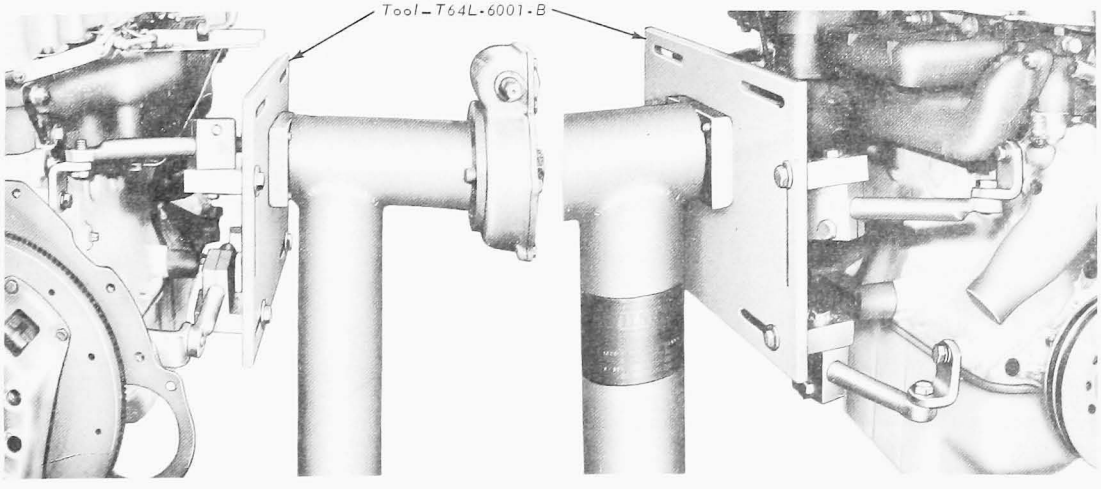

FIG. 38 Engine Mounted on Work Stand—Typical

4. Rotate the crankshaft in the direction of engine rotation to force the bearing out of the block.
5. Clean the crankshaft journal. When replacing standard bearings with new bearings, it is good practice to first try to obtain the proper clearance with standard bearings or a combination of a standard bearing and a 0.001 or 0.002 inch undersize bearing.

Installation

1. **The upper and lower bearing halves are not interchangeable. The upper half is drilled and grooved to provide entry of oil.** To install the upper main bearing, place the plain end of the bearing over the shaft on the locking tang side of the block and partially install the bearing so that tool 6331 can be inserted in the oil hole in the crankshaft journal. With tool 6331 positioned in the oil hole, rotate the crankshaft slowly in the opposite direction of engine rotation until the bearing is seated. Remove the tool.

   Select-fit the bearing for proper clearance following procedures given under Fitting Main and Connecting Rod Bearings in Part 21-01.
2. After the bearing has been fitted, apply a light coat of engine oil to the journal and bearings, then install the bearing cap. Torque the cap bolts to specifications.
3. Repeat the procedure for the remaining bearings that require replacement.
4. If the thrust bearing cap (No. 5 main bearing) has been removed, install it as follows:

   Install the thrust bearing cap with the bolts finger-tight. Pry the crankshaft forward against the thrust surface of the upper half of the bearing (Fig. 40). Hold the crankshaft forward and pry the thrust bearing cap to the rear. This will align the thrust surfaces of both halves of the bearing. Retain the forward pressure on the crankshaft. Torque the cap bolts to specifications.
5. **If the rear main bearing is replaced (on a work stand), apply a bead of oil-resistant sealer in each corner of the rear main bearing cap saddle the full length of the saddle. Be sure the main bearing is fitted and the cap bolts torqued to specifications before installing the new crankshaft rear oil seal.**
6. Clean the oil pump inlet tube screen. Prime the oil pump by filling the inlet opening with oil and rotate the pump shaft until the oil emerges from the outlet opening.
7. Install the oil pump and oil pan, following the procedure under Oil Pan Installation.
8. Fill the crankcase and cooling system. Start the engine and check for oil pressure. Operate the engine at fast idle and check for oil and coolant leaks.

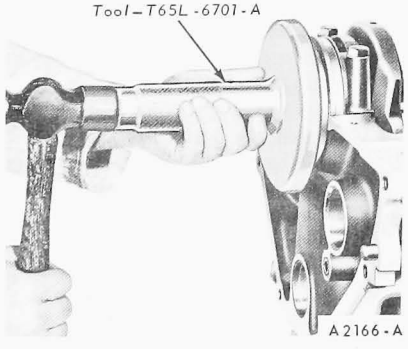

FIG. 39 Installing Crankshaft Rear Oil Seal

CONNECTING ROD BEARING

Removal

1. Drain the crankcase. Remove the oil pan and oil pump, following the procedure under Oil Pan Removal.
2. Turn the crankshaft until the connecting rod to which new bearings are to be fitted is down. Remove the connecting rod cap.

Installation

1. Install the bearing inserts in the connecting rod and cap with the tangs fitted in the slots.
2. Pull the connecting rod assembly down firmly on the crankshaft journal.

   Fit the bearing following procedures given in Part 21-01 under Fitting Main and Connecting Rod Bearings.
3. After the bearing has been fitted, clean and apply a light coat of engine oil to the journal and bearings. Install the connecting rod cap and torque the nuts to specifications.
4. Repeat the procedure for the remaining connecting rods that require new bearings.
5. Install the oil pan and oil pump, following the procedures under Oil Pan Installation in this section.
6. Fill the crankcase and cooling system. Start the engine and check for oil pressure. Operate the engine at fast idle and check for oil and coolant leaks.

   Remove the bearing inserts from the rod and cap.
3. Be sure the bearing inserts and the bearing bore in the connecting rod

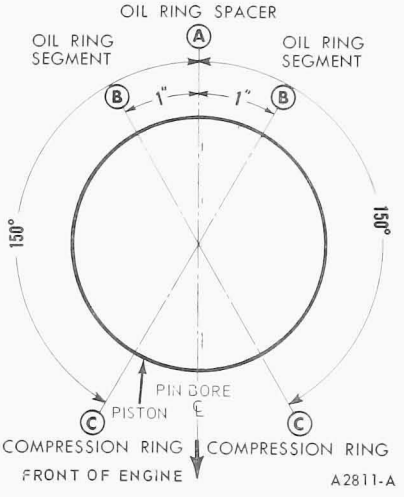

FIG. 41 Piston Ring Gap Spacing

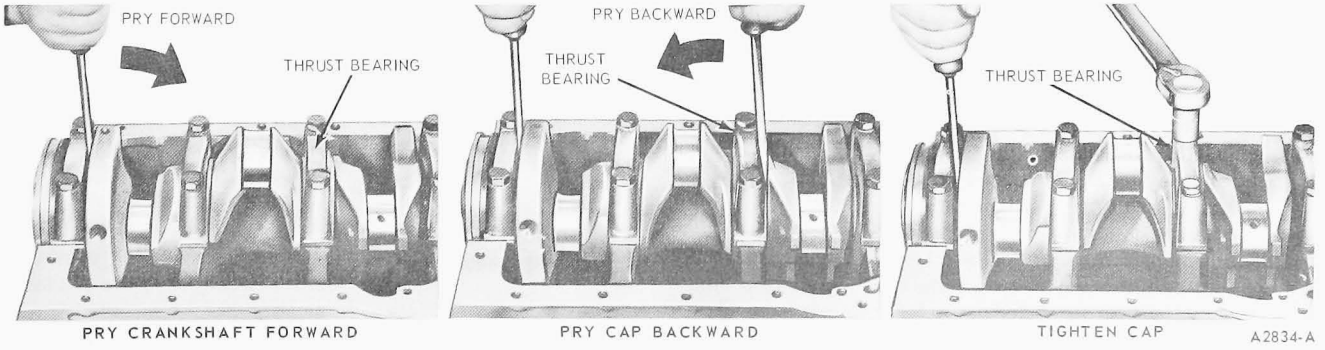

FIG. 40 Aligning Thrust Bearing

and cap are clean. Foreign material under the inserts will distort the bearing and cause a failure.

4. Clean the crankshaft journal. **When replacing standard bearings with new bearings, it is good practice to first try to obtain the proper clearance with standard bearings.**

Refer to Part 21-01 for the cleaning and inspection procedures.

PISTONS AND CONNECTING RODS

Removal

1. Drain the cooling system and the crankcase.
2. Refer to Cylinder Head Removal and remove the cylinder head and related parts.
3. Remove the oil pan following the procedure under Oil Pan Removal. Remove the oil pump inlet tube and the oil pump.
4. Turn the crankshaft until the piston to be removed is at the bottom of the stroke and place a cloth on the piston head to collect the cuttings. Remove any ridge and/or deposits from the upper end of the cylinder bore with a ridge cutter. Follow the instructions furnished by the tool manufacturer. **Never cut into the ring travel area in excess of 1/32 inch when removing ridges.**
5. Make sure all the connecting rod caps are marked so that they can be installed in their original positions. Remove the connecting rod cap.
6. Push the connecting rod and piston assembly out the top of the cylinder with the handle end of a hammer. Avoid damage to the crankshaft journal or the cylinder wall when removing the piston and rod.

Installation

1. Clean the oil pump inlet tube screen and the oil pan and block gasket surfaces.
2. Oil the piston rings, pistons and cylinder walls with light engine oil.
3. **Be sure to install the pistons in the same cylinders from which they were removed or to which they were fitted. The connecting rods and bearing caps are numbered from 1 to 6 beginning at the front of the engine. The number on the connecting rod and bearing cap must be on the same side of rod when installing in the cylinder bore. If a connecting rod is ever transferred from one cylinder block to another or from one cylinder to another, new bearings should be fitted and the connecting rod should be re-numbered to correspond with the new cylinder number.**

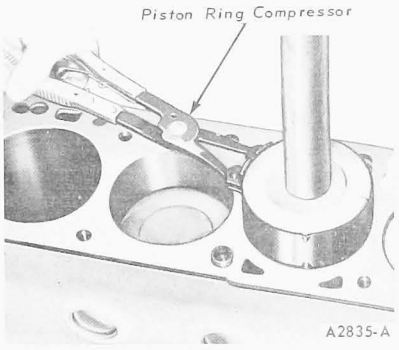

FIG. 42 Piston Installation

4. Make sure the ring gaps are properly spaced around the circumference of the piston (Fig. 41). Oil the rings, then install a piston ring compressor on the piston. Make sure that the indentation in the head of piston is toward the front, then push the piston into its bore with the handle end of a hammer until it is slightly below the top of the cylinder (Fig. 42). Be sure to guide the connecting rods to avoid damaging the crankshaft journals.
5. Check the clearance of each bearing following the procedure under Connecting Rod Bearing Replacement.
6. After the bearings have been fitted, apply a light coat of engine oil to the journals and bearings.
7. Turn the crankshaft throw to the bottom of its stroke, then push the piston all the way down until the connecting rod bearing seats on the crankshaft journal. Install the connecting rod cap. Torque the nuts to specifications.
8. After the piston and connecting rod assemblies have been installed, check the connecting rod side clearance on each crankshaft journal (Fig. 43).
9. Prime the oil pump by filling the inlet opening with oil and rotate the pump shaft until oil emerges from the outlet opening. Install the oil pump and the oil pump inlet tube. Install the oil pan and related parts.
10. Refer to Cylinder Head Installation and install the cylinder head and related parts. Adjust the valve clearance as described in this Part.
11. Fill and bleed the cooling system. Fill the crankcase.
12. Start the engine and check for oil pressure. Operate the engine at fast idle and check for oil and coolant leaks.

CRANKSHAFT

The crankshaft and related parts are shown in Fig. 44.

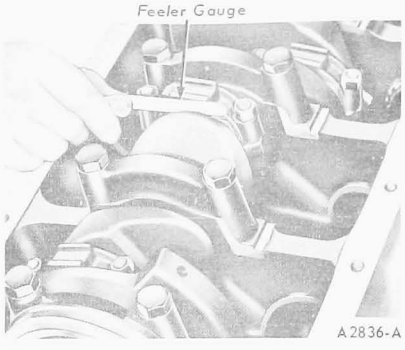

FIG. 43 Checking Connecting Rod Side Clearance

13. Operate the engine until engine temperatures have stabilized. Check and adjust the ignition timing. Adjust the engine idle speed and fuel mixture.

On a vehicle with an automatic transmission, adjust the transmission control linkage.

Removal

1. Install the engine on a work stand. Remove the spark plugs to allow easy rotation of the crankshaft.
2. Remove the oil level dipstick.
3. Remove the crankshaft damper attaching bolt and lock washer. Remove the crankshaft damper (Fig. 21).
4. Remove the cylinder front cover and gasket.
5. Remove the flywheel and engine rear cover plate.
6. Turn the engine on the work stand so that the bottom of the engine is up. Remove the oil pan, gaskets and seals. Remove the oil pump and inlet tube assembly. Discard the oil pump gasket.
7. Use an awl to punch two holes in the crankshaft rear oil seal. Punch the holes on opposite sides of the crankshaft and just above the bearing cap to cylinder block split line. Install a sheet metal screw in each hole. Use two large screwdrivers or small pry bars and pry against both screws at the same time to remove the crankshaft rear oil seal. It may be necessary to place small blocks of wood against the cylinder block to provide a fulcrum point for the pry bars. **Use caution throughout this procedure to avoid scratching or otherwise damaging the crankshaft oil seal surface.**
8. **Make sure all bearing caps (main and connecting rod) are marked so that they can be installed in their original locations.** Turn the crankshaft until the connecting rod from which the cap is being removed

is at the bottom of the stroke. Remove the connecting rod cap and bearings. Push the connecting rod and piston assembly up in the cylinder. **Do not turn the crankshaft completely around as the rod bolts may damage the crankpin journals.** Repeat this procedure and remove all connecting rod caps.

9. Remove the clutch pilot bushing if necessary (Fig. 34).
10. Align the timing marks (Fig. 27). Remove the crankshaft gear (Fig. 32).
11. Remove the main bearing caps and bearings.
12. Carefully lift the crankshaft out of the cylinder block so that the thrust bearing surfaces are not damaged. **Handle the crankshaft with care to avoid possible fracture or damage to the finished surfaces.**

Refer to Part 21-01 for the cleaning and inspection procedures. Be sure the oil seal surfaces on the crankshaft and crankshaft damper are properly cleaned.

To refinish journals, dress minor imperfections, etc., refer to Part 21-01.

Installation

1. Remove the main bearing inserts from the block and bearing caps.
2. Remove the bearing inserts from the connecting rod caps.
3. Clean the crankshaft rear oil seal recess in the cylinder block and rear main bearing cap.
4. If the crankshaft main bearing journals have been refinished to a definite undersize, install the correct undersize bearings. Be sure the bearing inserts and bearing bores are clean. Foreign material under the inserts will distort the bearing and cause a failure.
5. Place the upper main bearing inserts in position in the bore with the tang fitting in the slot provided. Be sure the oil holes in the bearing inserts are aligned with the oil holes in the cylinder block transverse webs.
6. Install the lower main bearing inserts in the bearing caps with the tang fitted in the slot.
7. Carefully lower the crankshaft into place. **Be careful not to damage the bearing surfaces.**
8. Check the clearance of each main bearing following procedures given in Part 21-01 under Fitting Main and Connecting Rod Bearings.
9. After the bearings have been installed, apply a light coat of heavy engine oil to the journals and bearings. Install all the bearing caps, except the thrust bearing cap (No. 5 bearing). **Be sure that the main bearing caps are installed in their original locations.** Torque the bearing cap bolts to specifications.
10. Install the thrust bearing cap with the bolts finger-tight.
11. Pry the crankshaft forward against the thrust surface of the upper half of the bearing (Fig. 40).
12. Hold the crankshaft forward and pry the thrust bearing cap to the rear. This will align the thrust surfaces of both halves of the bearing.
13. Retain the forward pressure on the crankshaft. Torque the cap bolts to specifications.
14. Check the crankshaft end play (refer to Part 21-01).
15. If the end play exceeds the wear limit, replace the thrust bearing. If the end play is less than the minimum limit, inspect the thrust bearing faces for scratches, burrs, nicks or foreign matter. If the thrust faces are not damaged or dirty, they probably need re-aligning. Install the thrust bearing and align the faces following the recommended procedure (Steps 8 thru 11). Then check the end play.
16. Coat a new crankshaft rear oil seal with oil and install it (Fig. 33). Inspect the seal to be sure it was not damaged during installation.
17. Install the bearing inserts in the connecting rods and caps. Check the clearance of each bearing following the procedure under Connecting Rod Bearing Replacement.
18. If the bearing clearances are to specifications, apply a light coat of engine oil to the journals and bearing.
19. Turn the crankshaft throw to the bottom of its stroke and pull the piston all the way down until the connecting rod bearing seats on the crankshaft journal.
20. Install the connecting rod cap and torque the nuts to specifications.
21. After the piston and connecting rod assemblies have been installed, check the connecting rod side

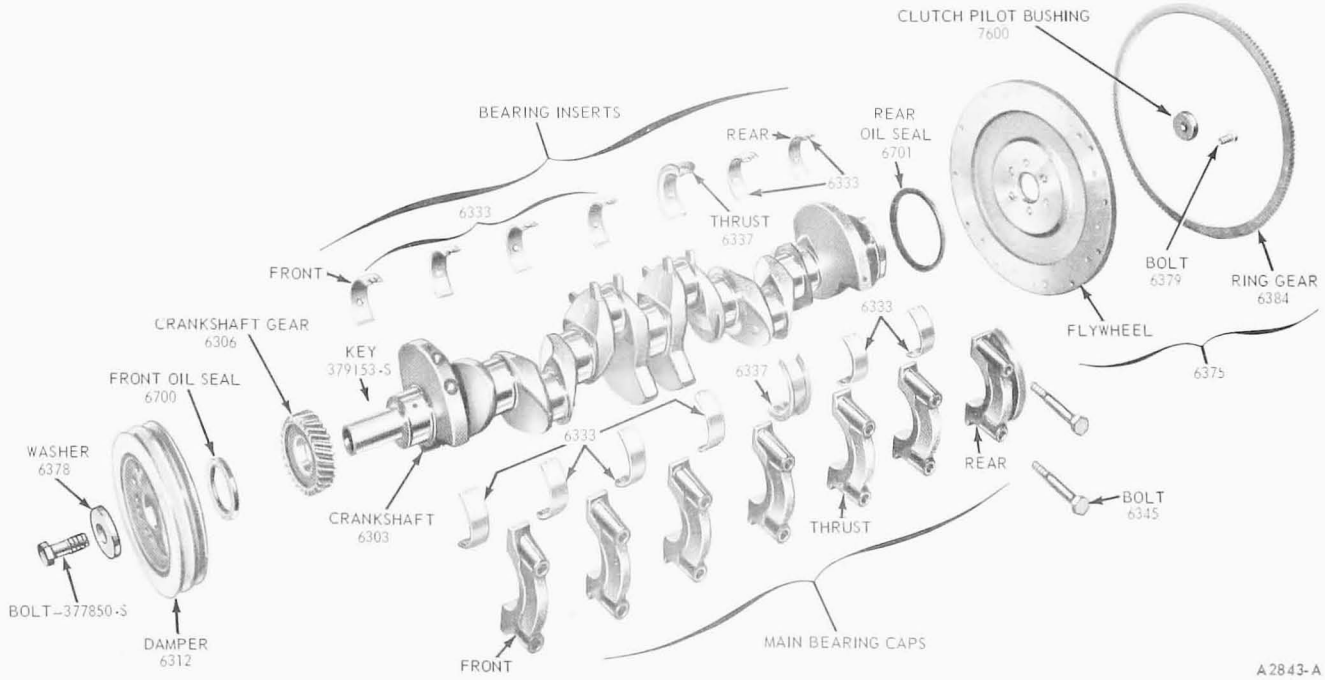

FIG. 44 Crankshaft and Related Parts

clearance on each crankshaft journal (Fig. 43).

22. Clean the oil pan, oil pump and oil pump screen.
23. Install the inlet tube and screen on the oil pump. Prime the oil pump by filling the inlet opening with oil and rotate the pump shaft until oil emerges from the outlet opening. Install it with a new gasket. Torque the attaching bolts to specifications.
24. On a crankshaft for a standard transmission, install the clutch pilot bushing (refer to Clutch Pilot Bushing Replacement).
25. Turn the engine on the work stand so that the rear of the engine is up. Position the engine rear cover plate on the cylinder block. Position the flywheel on the crankshaft. **Coat the threads of the attaching bolts with oil-resistant sealer and install the bolts.** Torque the bolts to specifications.

On a flywheel for a manual-shift transmission, locate the clutch disc following the procedure in Group 16. Install the pressure plate. Torque the attaching bolts to specifications.

26. Turn the engine on the work stand so that the front end is up.
27. Install the crankshaft gear following the procedure under Timing Gear Installation.
28. Install a new crankshaft front oil seal in the cylinder front cover (Fig. 22). Install the cylinder front cover and crankshaft damper by following the procedure outlined under Cylinder Front Cover Installation.
29. Apply oil-resistant sealer in the cavities between the bearing cap and cylinder block (Fig. 36). Install a new seal in the rear main bearing cap and apply a bead of oil-resistant sealer to the tapered ends of the seal. Install new side gaskets on the oil pan with oil-resistant sealer (Fig. 25). Position a new oil pan to cylinder front cover seal on the oil pan and install the oil pan.
30. Install the oil level dipstick.
31. Remove the engine from the work stand and install it in the vehicle.
32. Check the ignition timing and adjust if necessary.

CAMSHAFT BEARING

Camshaft bearings are available pre-finished to size for standard and 0.015-inch undersize journal diameters.

Removal

1. Remove the engine following the procedures in this Section and install it on a work stand (Fig. 38).
2. Remove the camshaft, flywheel and crankshaft, following the appropriate procedures. Push the pistons to the top of the cylinders.
3. Remove the camshaft rear bearing bore plug as detailed in Part 21-01. Remove the camshaft bearings with the tool shown in Fig. 45.
4. Select the proper size expanding collet and back-up nut and assemble on the expanding mandrel. With the expanding collet collapsed, install the collet assembly in the camshaft bearing and tighten the back-up nut on the expanding mandrel until the collet fits the camshaft bearing.
5. Assemble the puller screw and extension (if necessary) as shown and install on the expanding mandrel. Wrap a cloth around the threads of the puller screw to protect the front bearing or journal. Tighten the pulling nut against the thrust bearing and pulling plate to remove the camshaft bearing. Be sure to hold a wrench on the end of the puller screw to prevent it from turning.
6. To remove the front bearing, install the puller screw from the rear of the cylinder block.

Installation

1. Position the new bearings at the bearing bores, and press them in place with the tool shown in Fig. 45. Be sure to center the pulling plate and puller screw to avoid damage to the bearing. **Failure to use the correct expanding collet can cause severe bearing damage.** Align the oil holes in the bearings with the oil holes in the cylinder block before pressing bearings into place. **Be sure the front bearing is installed the specified distance below the front face of the cylinder block.**
2. Install the camshaft rear bearing bore plug as detailed in Part 21-01.
3. Install the camshaft, crankshaft, flywheel and related parts, following the appropriate procedures. Do not check connecting rod and main bearing clearances as a part of Camshaft Bearing Replacement.
4. Install the engine in the vehicle, following the procedures in this Section.

OIL FILTER

DISPOSABLE-TYPE

1. Place a drip pan under the oil filter. Unscrew the filter from the cylinder block with a filter wrench.
2. Coat the gasket on the filter with oil. Place the filter in position on the cylinder block (Fig. 46). Hand-tighten the filter until the gasket contacts the adapter face, then advance it 1/2 turn.
3. Operate the engine at fast idle and check for oil leaks. If oil leaks are evident, perform the necessary repairs to correct the leakage. Check the oil level and fill the crankcase if necessary.

REPLACEABLE ELEMENT-TYPE

The oil filter assembly is shown in Fig. 47.

1. Place a drip pan under the filter. Remove the filter center bolt, then remove the filter assembly and gasket. Discard the gasket.
2. Remove the filter element, neoprene gasket, spring and seat. Then remove the center bolt from the container and the fiber gasket from the bolt. Discard the element and gaskets.
3. Wash all parts in solvent. Make sure the openings in the bolt are clean.
4. Install the new filter element in the housing following the instructions furnished with the new element.
5. Clean the cylinder block filter recess. Install a new gasket.
6. Place the filter assembly in position and thread the center bolt into the adapter finger-tight.
7. Rotate the filter assembly slightly, in each direction, to make sure the gasket is seated evenly.
8. Torque the bolt to specifications. **Do not over-torque the bolt.**
9. Add oil to the crankcase if necessary. Operate the engine at fast idle and check for oil leaks.

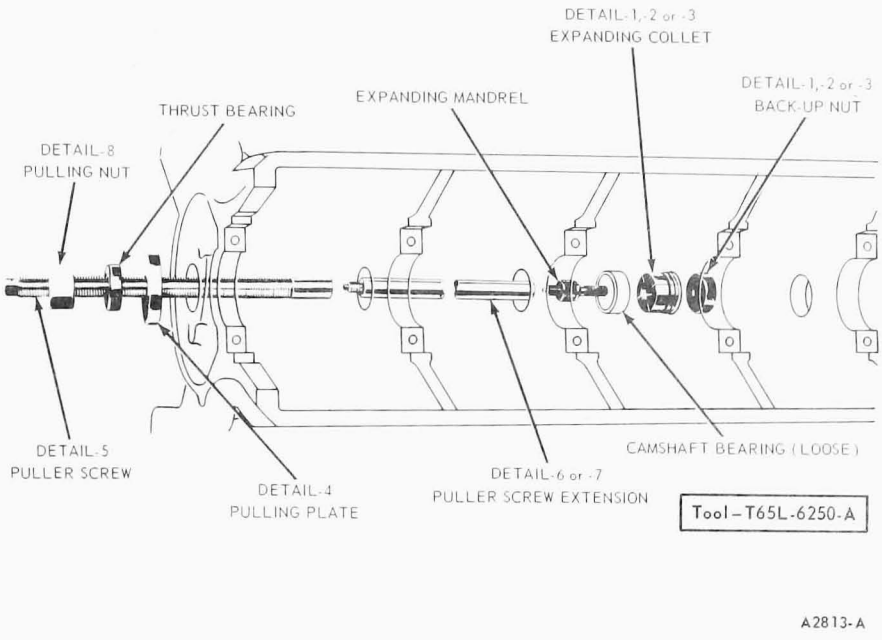

FIG. 45 Replacing Camshaft Bearing

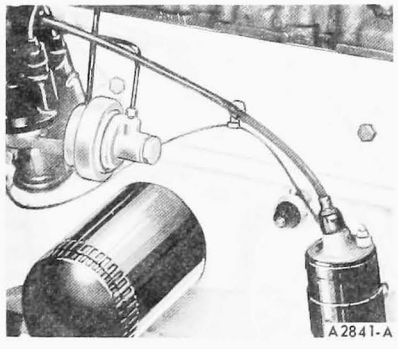

FIG. 46 Oil Filter Installed—Typical

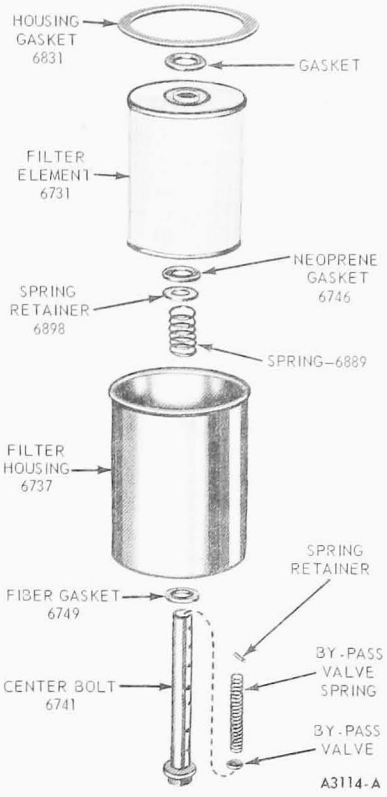

FIG. 47 Typical Replaceable Element Type Oil Filter Assembly

DISASSEMBLY AND ASSEMBLY

When installing nuts or bolts that must be torqued (refer to torque specifications), oil the threads with light weight engine oil. **Do not oil threads that require oil-resistant or water-resistant sealer.**

ENGINE ASSEMBLY

Disassembly

1. Remove the engine left front support insulator from the engine.
2. Install the engine on a work stand (Fig. 38).
3. Disconnect the spark plug wires at the spark plugs. Disconnect the distributor high tension lead at the coil. Remove the distributor cap and spark plug wires as an assembly.
4. Disconnect the fuel line at the carburetor and fuel pump. Disconnect the vacuum line at the distributor and carburetor. Remove the fuel and vacuum lines.
5. Remove the fuel pump and discard the gasket.
6. Remove the oil pressure sending unit and the oil level dipstick.
7. Disconnect the distributor primary wire at the coil, then remove the distributor. Remove the ignition coil and bracket assembly.
8. Remove the oil filter and oil filter mounting adapter. If equipped, remove the air compressor.
9. Remove the crankcase ventilation regulator valve from the valve rocker arm cover. Remove the rocker arm cover.
10. Loosen the rocker arm stud nuts, rotate the rocker arms to one side and remove the push rods in sequence. Place the push rods in a rack so they can be installed in the same location from which they were removed.
11. Remove the valve push rod cover. Remove the valve lifters and place

them in order so they may be installed in the same bores from which they were removed (Fig. 20).
12. Remove the water pump.
13. Remove the carburetor, intake and exhaust manifold and cylinder head as an assembly.
14. Remove the crankshaft damper (Fig. 21). Remove the cylinder front cover. Remove the crankshaft front oil seal from the cylinder front cover.
15. Remove the flywheel and engine rear cover plate.
16. Remove the oil pan and oil pump and pickup tube assembly. Discard the gaskets and seals.
17. Check the camshaft end play, the timing gear backlash and the timing gear runout (Part 21-01). Position the camshaft gear as shown in Fig. 28 and remove the camshaft thrust plate screws. Remove the camshaft, thrust plate and gear as an assembly.
18. Remove the crankshaft gear as shown in Fig. 32.
19. Remove any ridge and/or deposits from the upper end of the cylinder bores. Remove the cylinder ridge with a ridge cutter. Follow the instructions furnished by the tool manufacturer. **Never cut into the ring travel area in excess of 1/32 inch when removing ridges.**
20. **Make sure all bearing caps (main and connecting rod) are marked so that they can be installed in their original locations.** Turn the crankshaft until the connecting rod being removed is down. Remove the connecting rod cap.
21. Push each connecting rod and piston assembly out the top of the cylinder with the handle end of a hammer. **Avoid damage to the crankshaft journal or the cylinder wall when removing the piston and rod.**
22. Remove the bearing inserts from the connecting rods and caps. Install the rod caps on the connecting rods from which they were removed.
23. Remove the main bearing caps. Carefully lift the crankshaft out of the cylinder block so that the thrust bearing surfaces are not damaged. Remove the crankshaft rear oil seal. **Handle the crankshaft with care to avoid possible fracture or damage to the finished surfaces.**
24. Remove the main bearing inserts from the cylinder block and main bearing caps.
25. Remove oil dipstick tube from the cylinder head dowel pins and cylinder block drain plugs.
26. Disassemble the pistons, piston rings and connecting rods, following the procedures under Pistons and Connecting Rods Disassembly.
27. If the camshaft gear is to be removed from the camshaft, press the camshaft out of the gear in an Arbor Press. Remove the thrust plate and spacer.
28. Remove the camshaft rear bearing bore plug as detailed in Part 21-01. Remove the camshaft bearings. Refer to Camshaft Bearing Replacement.
29. Remove the carburetor, EGR valve and spacer from the intake manifold and discard the gaskets. Remove the intake and exhaust manifolds from the cylinder head and separate the manifolds. Disassemble the cylinder head, removing the rocker arms, valves, valve springs, coolant outlet elbow, etc. Place all parts in a rack or identify them so they can be installed in the same location from which they were removed.

Assembly

Many of the procedures given here are condensed from other sections of this Group.

1. Clean and inspect all parts per the appropriate procedures in Part 21-01, except do not disassemble the oil pump and hydraulic lifters for cleaning.
2. Remove the glaze from the cylinder bores by following the procedures in Part 21-01, Refinishing Cylinder Walls.
3. Invert the engine on the work stand. Position new camshaft bearings in the cylinder block, making sure that the oil holes in the bearing are aligned with those in the block. Press them in place (Fig. 45). **Be sure the camshaft front bearing is installed the specified distance below the front face of the cylinder block.**
4. Install a new camshaft rear bearing bore plug as detailed in Part 21-01.
5. Oil the camshaft bearing journals and apply Lubriplate or equivalent to all the lobes. Then carefully slide the camshaft through the bearings.
6. If the camshaft gear was removed, install the spacer, thrust plate and gear, using the tool shown in Fig. 30. Install the thrust plate screws and torque to specifications.
7. If the crankshaft main bearing journals have been refinished to a definite undersize, install the correct undersize bearings. Be sure the bearing inserts and bearing bores are clean.
8. Place the upper main bearing inserts in position in the bore with the tang fitting in the slot provided.
9. Install the lower main bearing inserts in the bearing caps.
10. Carefully lower the crankshaft into place. **Be careful not to damage the bearing surfaces.**
11. Check the clearance of each main bearing following the procedure given in this Section.
12. After the bearings have been fitted, apply a light coat of engine oil to the journals and bearings. Install all the bearing caps, except the thrust bearing cap (No. 5 bearing). **Be sure that the main bearing caps are installed in their original locations. Torque the bearing cap bolts to specifications.**
13. Install the thrust bearing cap and check the crankshaft end play by following steps 11 thru 16 under Crankshaft Installation in this Section.
14. Check the camshaft end play, camshaft gear backlash following the procedures in Part 21-01. If the end play exceeds specifications, replace the thrust plate. If the gear backlash exceeds specifications, replace the camshaft gear (and crankshaft gear as necessary).
15. Check the camshaft gear runout with a dial indicator (Part 21-01). If the gear runout is excessive, replace the gear.
16. Check the piston to cylinder bore fit of each piston following the procedure in Part 21-01.
17. Check the end gap of all piston rings (Part 21-01). Assemble the pistons piston rings and connecting rods, following the procedure under Pistons and Connecting Rods Assembly. Check the piston ring side clearance (Part 21-01).
18. Install the piston and connecting rod assemblies and check the clearance of the connecting rod bearings. Refer to Piston and Connecting Rod Installation and Connecting Rod Bearing Replacement.
19. Coat a new crankshaft front oil seal with grease and install it in the cylinder front cover (Fig. 22).
20. Coat the gasket surfaces of the cylinder front cover and cylinder block with oil-resistant sealer. Position the gasket on the block and install the cover (Fig. 23). Torque the bolts to specifications.
21. Lubricate the damper end of the crankshaft with a white lead and oil mixture. Apply Lubriplate or equivalent to the seal surface of the front oil seal. Apply Lubriplate or equivalent to the seal surface of the crankshaft damper and install the crankshaft damper (Fig. 24).

22. Apply a light film of engine oil on a new crankshaft rear oil seal. Apply Lubriplate or equivalent to the seal contact surface of the crankshaft and install the seal (Fig. 39) the specified distance below the face of the cylinder block. Be sure the seal was not damaged during installation.
23. Position the engine rear cover plate on the rear of the cylinder block and install the flywheel on the crankshaft. **Apply oil-resistant sealer to the threads of the flywheel attaching bolts. Install the bolts and torque them to specifications.**
24. Prime the oil pump by filling the inlet opening with oil and rotate the pump shaft until oil emerges from the outlet opening. Use a new gasket and install the inlet tube and screen on the oil pump. Position a new gasket on the oil pump body and install the oil pump and inlet tube assembly. Torque the attaching bolts to specifications.
25. Apply oil-resistant sealer in the cavities between the bearing cap and cylinder block (Fig. 36). Install a new seal in the rear main bearing cap and apply a bead of oil-resistant sealer to the tapered ends of the seal.
26. Install new side gaskets on the oil pan with oil-resistant sealer (Fig. 25). Position a new cylinder front cover seal on the oil pan and install the oil pan.
27. Coat both sides of a new water pump gasket with water-resistant sealer and position the gasket on the cylinder block. Coat the threads of the water pump bolts with water-resistant sealer. Install the water pump. Torque the bolts to specifications.
28. Assemble the valves, springs, rocker arms, coolant outlet elbow, etc., following the procedures under Cylinder Head.
29. Place a new cylinder head gasket on the block. Carefully position the cylinder head on the block and install the bolts. Torque the bolts in sequence (Fig. 17) to specifications. When cylinder head bolts have been tightened it is not necessary to re-torque the bolts after extended operation. However, the bolts may be checked and re-torqued, if desired.
30. Clean the exterior surface of the valve lifters with a clean, lint-free cloth and oil the surface with engine oil. Install the valve lifters (Fig. 20) in the same sequence that they were removed.
31. Apply Lubriplate or equivalent to both ends of the push rods and to the push rod bores in the cylinder head. Install the push rods in the same sequence that they were removed. Be sure the push rods are properly seated in the valve lifters. Engage the rocker arms with the push rods and tighten the stud nuts sufficiently to hold the push rods in place.
32. Adjust the valve clearance as described in this Part.
33. Coat the gasket surface of the push rod cover with oil-resistant sealer and position a new gasket on the cover. Install the cover and gasket on the cylinder block. Torque the cover bolts in sequence to specifications.
34. Install the carburetor, EGR valve, spacer, intake and exhaust manifold, following the procedure under Intake and Exhaust Manifolds Installation.
35. Clean the valve rocker arm cover. Place the new gaskets in the covers making sure that the tabs of the gasket engage the notches provided in the cover. Install the cover on the cylinder head and torque the cover screws in sequence to specifications. Install the crankcase ventilation regulator valve in the rocker arm cover. Attach the vent hose to the intake manifold inlet tube.
36. Install the cylinder block drain plugs and oil pressure sending unit. Install the oil level dipstick tube and dipstick.
37. Install the oil filter mounting adapter. Coat the seal surface of a new oil filter with grease (or engine oil). Install the oil filter until the seal surface contacts the cylinder block, then tighten the filter an additional 1/2 turn.
38. Install the ignition coil and bracket.
39. Position No. 1 cylinder on TDC after the compression stroke. Set the distributor points to No. 1 cylinder firing position and install the distributor. With the distributor ignition points open position (No. 1 cylinder) install the hold-down clamp and screw. Tighten the screw snug, but not tight.
40. Use a new gasket and install the fuel pump. Torque the bolts to specifications. Install the carburetor fuel inlet line and distributor vacuum line. Install the air compressor, if so equipped.
41. Install the distributor cap and spark plug wires. Connect the spark plug wires. Connect the distributor primary and secondary high tension wires to the ignition coil.
42. Remove the engine from the work stand. Install the engine left front support insulator on the engine.

CYLINDER HEAD

Disassembly

1. Remove the coolant outlet housing and thermostat. Discard the gasket.
2. Remove the intake manifold, exhaust manifold and carburetor as an assembly from the cylinder head. Discard the gasket.
3. Remove the spark plugs.
4. Remove the deposits from the combustion chambers and valve heads with a scraper and a wire brush before removing the valves. **Be careful not to scratch the cylinder head gasket surface.**
5. Compress the valve springs (Fig. 48), then remove the valve spring retainer locks and release the spring.
6. Remove the spring retainer, spring, stem seal and valve (Fig. 49). Discard the valve stem seals. Identify all valve parts.

Assembly

1. Lubricate the valve guides and valve stems with heavy engine oil. Apply Lubriplate or equivalent to the tip of the valve stems.
2. Install each valve in the valve guide from which it was removed or to which it was fitted.
3. Oil and install a new intake valve oil seal (Fig. 49). Do not install the O-ring type seal on the exhaust valves at this time.
4. Install the valve spring over the valve. **Be sure the closed coil end is placed against the cylinder head.**
5. Position the spring retainer on all valve springs. Make sure that a positive rotating retainer is used on all of the exhaust valves (Fig. 49).
6. Compress the spring (Fig. 48). Apply engine oil to the O-ring type seal, then install it on the exhaust valve. Install the retainer locks.

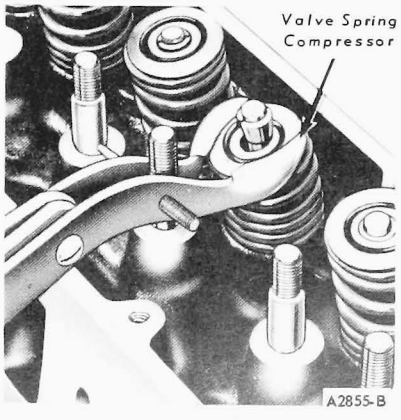

FIG. 48 Compressing Valve Spring on Bench

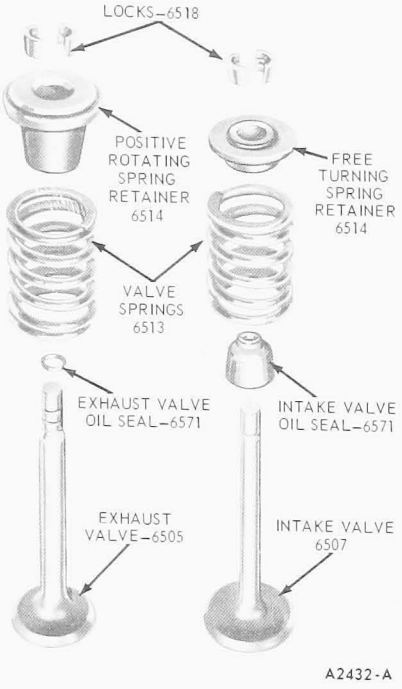

FIG. 49 Valve Assembly

7. Measure the assembled height of the valve spring from the surface of the cylinder head spring pad to the underside of the spring retainer with dividers (Fig. 50).

Check the dividers against a scale. If the assembled height is greater than the specified limit, install the necessary 0.030 inch thick spacer(s) between the cylinder head spring pad and the valve spring to bring the assembled height to the recommended dimension. **Do not install spacers unless necessary. Use of spacers in excess of recommendations will result in overstressing the valve springs and overloading the camshaft lobes which could lead to spring breakage and worn camshaft lobes.**

8. Position a new intake manifold gasket on the cylinder head. Install the intake manifold, exhaust manifold and carburetor as an assembly. Torque the manifold bolts and nuts in sequence (Fig. 16) to specifications.
9. Using a new gasket coated with water-resistant sealer, install the thermostat and coolant outlet elbow. Torque the attaching bolts to specifications.

VALVE LIFTER

The disassembly and assembly procedures for Types I and II valve lifters are different. Valve lifters should always be tested after assembly. Refer to the test procedures covered in Part 21-01.

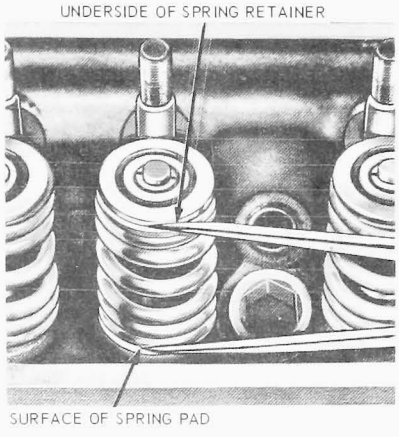

FIG. 50 Checking Valve Spring Assembled Height—Typical

TYPE I

Disassembly

Each valve lifter is a matched assembly. If the parts of one lifter are intermixed with those of another, improper valve operation may result. Disassemble and assemble each lifter separately. Keep the lifter assemblies in proper sequence so that they can be installed in their original bores.

1. Grasp the lock ring with needle nose pliers to release it from the groove. It may be necessary to depress the plunger to fully release the lock ring.
2. Remove the push rod cup, metering valve (disc), plunger and spring.
3. Invert the plunger assembly and remove the check valve retainer by carefully prying up on it with a screwdriver. Remove the check valve (disc or ball check) and spring.

For the cleaning and inspection procedures, refer to Part 21-01.

Assembly

Type I hydraulic valve lifter assembly is shown in Fig. 51.

1. Place the plunger upside down on a clean work bench.
2. Place the check valve (disc or ball check) in position over the oil hole on the bottom of the plunger. Set the check valve spring on top of the check valve (disc or ball check).
3. Position the check valve retainer over the check valve and spring and push the retainer down into place on the plunger.
4. Place the plunger spring and then the plunger (open end up) into the lifter body.
5. Position the metering valve (disc) in the plunger and then place the push rod seat in the plunger.
6. Depress the plunger and position the closed end of the lock ring in the groove of the lifter body. With the plunger still depressed, position the open ends of the lock ring in the groove. Release the plunger and then depress it again to fully seat the lock ring.
7. Use the hydraulic valve lifter leakdown tester (Part 21-01) to fill the lifters with test fluid.

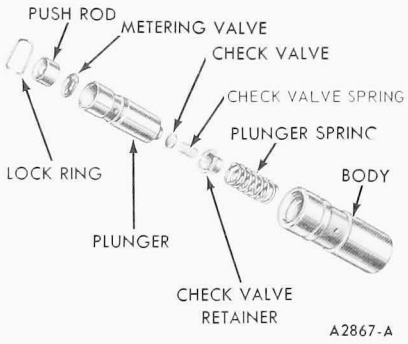

FIG. 51 Type I Hydraulic Valve Lifter Assembly

TYPE II

Disassembly

Each valve lifter is a matched assembly. If parts of one lifter are intermixed with those of another, improper valve operation may result. Disassemble and assemble each lifter separately. Keep the lifter assemblies in proper sequence so they can be installed in their original bores.

1. Grasp the lock ring with needle nose pliers to release it from the groove. It may be necessary to depress the plunger to fully release lock ring.
2. Remove the push rod cup.
3. Remove the plunger assembly, the check valve and the check valve retainer and plunger spring. Carefully remove the plunger spring, the check valve retainer and the check valve ball and spring from the plunger.

Assembly

Type II hydraulic lifter assembly is shown in Fig. 52.

1. Place the plunger on a clean work surface (table or bench) in an inverted position and center the check valve ball and spring on it. Carefully slide the check valve retainer over the ball and spring and down until it bottoms. **Use every precaution not to distort it in any way.** Place the plunger spring over the metering valve.
2. Leaving the assembly in the inverted position, slide the lifter body down over the spring until it slightly compresses the spring.
3. Position the combined assembly right side up on the work surface

(table or bench).
4. Install the push rod cup. Depress the cup and install the lock ring.
5. Use the hydraulic valve lifter leakdown tester (Part 21-01) to fill the lifters with test fluid.

OIL PUMP

Disassembly

1. Remove the cover attaching screws and remove the cover (Fig. 53).
2. Remove the inner rotor and shaft assembly, then remove the outer race.
3. Scrape away the staking marks on the body around the oil pressure relief valve cap. Drill a 1/8-inch hole in the relief valve cap and insert a self-threading sheet metal screw of proper diameter into the cap. Pull the cap out of the chamber. Remove the spring and plunger.

Refer to Part 21-01 for the cleaning and inspection and repair procedures.

Assembly

1. Clean all parts thoroughly. Install the oil pressure relief valve plunger, spring and new cap. Stake the cap into position.
2. Install the outer race (recessed dot facing out on same side as dot on rotor) and the inner rotor and shaft assembly.

The inner rotor and shaft and the outer race are serviced as an assembly. One part should not be replaced without replacing the other.

3. Install the cover and torque the attaching screws to specifications.

PISTON AND CONNECTING ROD

Disassembly

1. Remove the bearing inserts from the connecting rod and cap.
2. Mark the pistons and pins to assure assembly with the same rod and installation in the same cylinder from which they were removed.
3. Remove the piston rings. Using an Arbor Press and the tool shown in Fig. 54, press the piston pin from the piston and connecting rod.

Refer to Part 21-01 for the Cleaning, Inspection and Repair procedures.

Assembly

The piston, connecting rod and related parts are shown in Fig. 55. **Check the fit of a new piston in the cylinder bore before assembling the piston and piston pin to the connecting rod following the procedures in Part 21-01.**

The piston pin bore of a connecting rod and the diameter of the piston pin must be within specifications.

1. Apply a light coat of engine oil to all parts. **Assemble the piston to the connecting rod with the bearing tang side of the connecting rod and the indentation notch in the piston positioned as shown in Fig. 56.**
2. Start the piston pin in the piston and connecting rod. Using an Arbor Press, press the piston pin through the piston and connecting rod until the pin is centered in the connecting rod (Fig. 57).
3. Check the end gap of all piston rings (Part 21-01). It must be within specifications. Follow the instructions contained on the piston ring package and install the piston rings.
4. Check the ring side clearance of the compression rings with a feeler gauge inserted between the ring and its lower land (Part 21-01). The gauge should slide freely around the entire ring circumference without binding. Any wear that occurs will form a step at the inner portion of the lower land. **If the lower lands have steps, the piston should be replaced.**
5. Be sure the bearing inserts and the bearing bore in the connecting rod and cap are clean. Foreign material under the inserts will distort the bearing and cause a failure. Install the bearing inserts in the connecting rod and cap with the tangs fitting in the slots provided.

CYLINDER ASSEMBLY

Disassembly

Follow steps 1 thru 17 under Engine Disassembly in this section. Remove the cylinder head dowels from the cylinder block. Remove the cylinder block drain plugs and remove the cylinder assembly from the work stand.

Clean the gasket and seal surfaces of all parts and assemblies (refer to Part 21-01).

Assembly

Install the replacement cylinder assembly on a work stand. Install the cylinder block drain plugs and cylinder head dowels. Transfer all parts removed from the old cylinder assembly to the

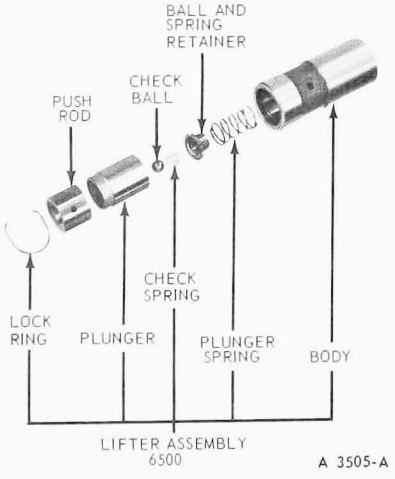

FIG. 52 Type II Hydraulic Valve Lifter Assembly

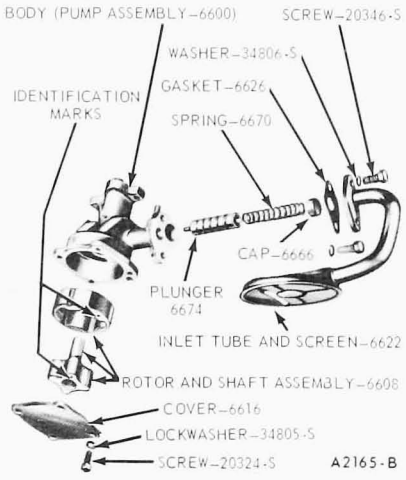

FIG. 53 Oil Pump Assembly

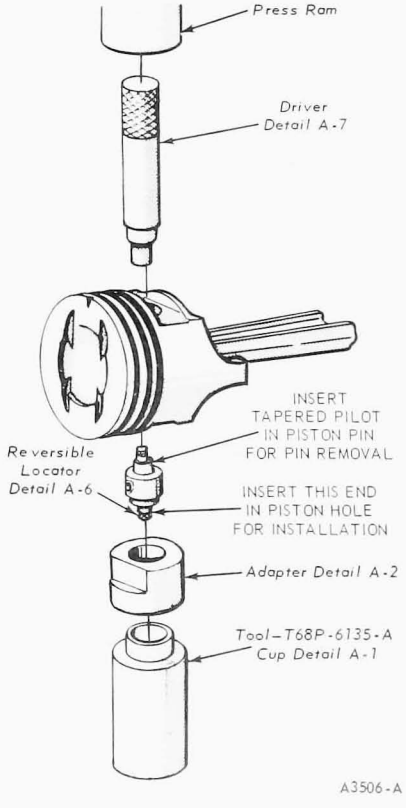

FIG. 54 Removing Piston Pin

new cylinder assembly, following the procedures in steps 19 thru 21, 23 thru 27, 29 thru 33 and 36 thru 44 under Engine Assembly in this section. When transferring parts to the new cylinder assembly, be sure all assembly clearances are within specified limits.

CYLINDER BLOCK

Disassembly

Follow steps 1 thru 27 under Engine Disassembly in this section. Remove the cylinder head dowels and cylinder block drain plugs. Remove the intake and exhaust manifolds and cylinder head as an assembly. Remove the cylinder block from the work stand. Clean the gasket and seal surfaces of all parts and assemblies (Part 21-01).

Assembly

Install the replacement cylinder block on a work stand. Install the cylinder block drain plugs and cylinder head dowels. Transfer all parts removed from the old cylinder block to the new cylinder block, following steps 5 thru 27, 29 thru 33, and 36 thru 44 under Engine Assembly in this section. Install the manifolds and cylinder head as an assembly. **Check all assembly clearances and correct as necessary.**

DESCRIPTION

ENGINE

The 302 V-8 engine is shown in Fig. 1 and is available in the Bronco, Econoline and F-100. This 8-cylinder engine has a piston displacement of 302 cubic inches and a compression ratio of 8.2:1.

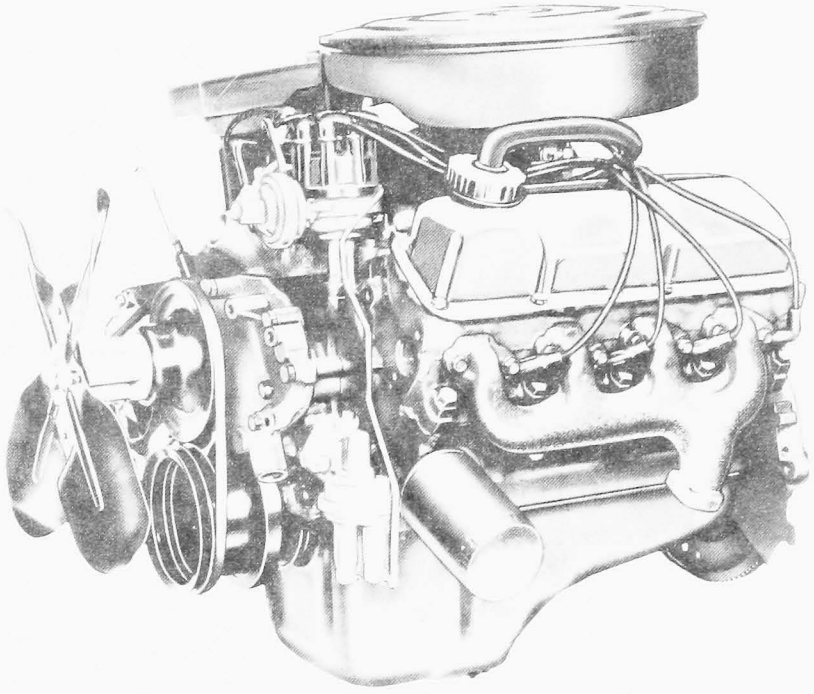
An engine identification tag is located behind or under the ignition coil bracket. Refer to Part 21-01 for the engine tag code.

EXHAUST EMISSION CONTROL SYSTEM

The Imco exhaust emission control system along with the EGR System (Exhaust Gas Recirculation) controls engine combustion at a level designed to reduce contaminants normally emitted through the exhaust system. This is accomplished by using a specially-calibrated carburetor and distributor. The EGR System is covered in Volume VI of this manual.

CRANKCASE VENTILATION SYSTEM

The engine is equipped with a positive closed-type crankcase ventilation system directing the crankcase vapors to the intake manifold.



A2715-D

FIG. 1 Left 3/4 Front View of Engine—Typical

ADJUSTMENTS

VALVE CLEARANCE

The valve arrangement of the left bank is E-I-E-I-E-I-E-I and on the right bank is I-E-I-E-I-E-I-E.

A 0.060 inch shorter push rod or a 0.060 inch longer push rod are available for service to provide a means of compensating for dimensional changes in the valve mechanism. Refer to the Master Parts List or the specifications for the pertinent color code.

Valve stem to valve rocker arm clearance should be within specifications with the hydraulic lifter completely collapsed. Repeated valve reconditioning operations (valve and/or valve seat refacing) will decrease the clearance to the point that if it is not compensated for, the hydraulic valve lifter will cease to function and the valve will be held open.

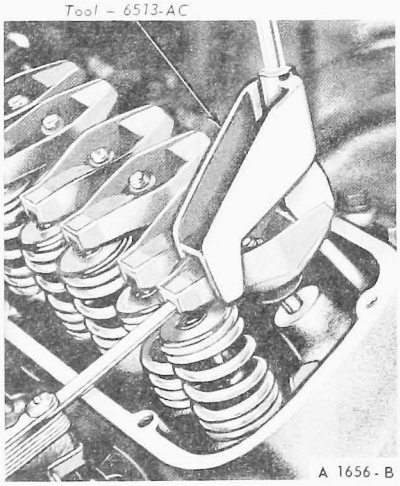


FIG. 2 Checking Valve Clearance—Hydraulic Valve Lifters

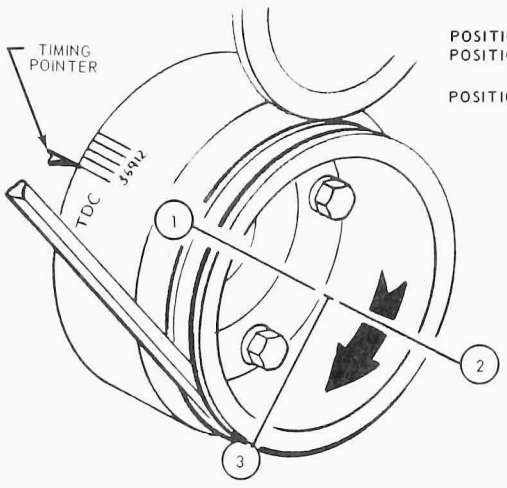
To determine whether a shorter or a longer push rod is necessary, make the following check:

1. Install an auxiliary starter switch. Crank the engine with the ignition switch OFF until the No. 1 piston is on TDC after the compression stroke.
2. With the crankshaft in the positions designated in Steps 3, 4 and 5, position the hydraulic lifter compressor tool on the rocker arm. Slowly apply pressure to bleed down the hydraulic lifter until the plunger is completely bottomed (Fig. 2). Hold the lifter in this position and check the available clearance between the rocker arm and the valve stem tip with a feeler gauge. The feeler gauge width must not exceed 3/8 inch.

If the clearance is less than

With No. 1 at TDC at end of compression stroke make a chalk mark at points 2 and 3 approximately 90 degrees apart.



POSITION 1 – No. 1 at TDC at end of compression stroke.
POSITION 2 – Rotate the crankshaft 180 degrees (one half revolution) clockwise from POSITION A.
POSITION 3 – Rotate the crankshaft 270 degrees (three quarter revolution) clockwise from POSITION 2.

A3234-B

FIG. 3 Position of Crankshaft for Checking and Adjusting Valve Clearance

specifications, install an undersize push rod.

If the clearance is greater than specifications, install an oversize push rod.

3. With the No. 1 piston on TDC at the end of the compression stroke, POSITION A in Fig. 3, check the following valves:
   No. 1 Intake No. 1 Exhaust
   No. 7 Intake No. 5 Exhaust
   No. 8 Intake No. 4 Exhaust
4. Rotate the crankshaft to POSITION B in Fig. 3 and check the following valves:
   No. 5 Intake No. 2 Exhaust
   No. 4 Intake No. 6 Exhaust
5. Rotate the crankshaft to POSITION C in Fig. 3 and check the following valves:
   No. 2 Intake No. 7 Exhaust
   No. 3 Intake No. 3 Exhaust
   No. 6 Intake No. 8 Exhaust

The positive stop rocker arm stud eliminates the necessity of adjusting the valve clearance. However, to obtain the specified valve clearance, it is important that all valve components be in a serviceable condition and installed and torqued properly. **Each stud nut should be removed and inspected for conditions shown in Fig. 4 when adjusting valve clearance.**

With the crankshaft in the positions designated in Steps 1, 2 and 3, **remove and inspect the stud nut for conditions shown in Fig. 4. Install and turn the stud nut clockwise until it contacts the stop. Tighten the nut to specifications.**

6. With the No. 1 piston on TDC at the end of the compression stroke, POSITION A in Fig. 3, set the valve clearance on the following valves:
   No. 1 Intake No. 1 Exhaust
   No. 7 Intake No. 5 Exhaust
   No. 8 Intake No. 4 Exhaust
7. Rotate the crankshaft to POSITION B in Fig. 3 and set the valve clearance on the following valves:
   No. 5 Intake No. 2 Exhaust
   No. 4 Intake No. 6 Exhaust
8. Rotate the crankshaft to POSITION C in Fig. 3 and set the valve clearance on the following valves:
   No. 2 Intake No. 7 Exhaust
   No. 3 Intake No. 3 Exhaust
   No. 6 Intake No. 8 Exhaust

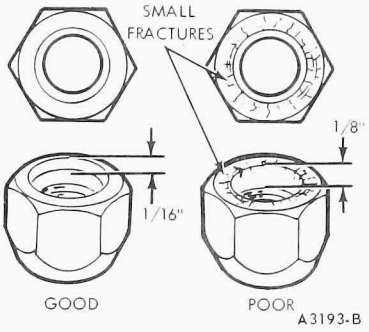


FIG. 4 Inspection of Rocker Arm Stud Nut

REMOVAL AND INSTALLATION

Most of the procedures in this section will require the removal of the engine cover on Econoline vehicles.

When installing nuts or bolts that must be tightened (Refer to torque specifications), oil the threads with light weight engine oil. **Do not oil threads that require oil-resistant or water-resistant sealer.**

Refer to Part 21-01 for Cleaning, Inspection and Test procedures.

ENGINE ASSEMBLY

The engine removal and installation procedures are for the engine only without the transmission attached.

F-100 AND BRONCO

Removal

1. Drain the cooling system and the crankcase.
2. Disconnect the battery and alternator ground cables from the cylinder block.
3. Remove the air cleaner and intake duct assembly, including the crankcase ventilation hose.
4. Disconnect the radiator lower and upper hose at the radiator. If equipped with an automatic transmission, disconnect the transmission oil cooler lines.
5. Remove the fan shroud and position

it over the fan. Remove the radiator. Remove the fan shroud, fan spacer, belts and pulley.

6. Disconnect the wires at the alternator adjusting bolts and allow the alternator to swing down and out of the way.
7. Disconnect the oil pressure sending unit wire from the sending unit, and the flexible fuel line at the fuel tank line. Plug the fuel tank line. Disconnect the windshield wiper vacuum line at the fuel pump.
8. Disconnect the accelerator rod from the carburetor.

Disconnect the transmission shift rod and remove the retracting spring if so equipped.

9. Disconnect the heater hoses from the water pump and intake manifold. Disconnect the water temperature sending unit wire from the sending unit.
10. Remove the flywheel housing-to-engine upper bolts.
11. Disconnect the primary wire from the ignition coil. Remove the wire harness from the left rocker arm cover and position the wires out of the way. Disconnect the ground strap from the cylinder block.
12. Raise the front of the vehicle. Disconnect the starter cable from the starter. Remove the starter.
13. Disconnect the muffler inlet pipes from the exhaust manifolds. Disconnect the engine support insulators from the brackets on the frame underbody.

On a vehicle with automatic transmission, remove the converter inspection plate. Remove the torque converter-to-flywheel attaching bolts.

Remove the remaining flywheel housing-to-engine bolts.

14. Lower the vehicle, and then support the transmission. Install the engine left lifting bracket on the front of the left cylinder head, and install the engine right lifting bracket at the rear of the right cylinder head. Then attach the engine lifting sling (Fig. 5).
15. Raise the engine slightly and carefully pull it from the transmission. Carefully lift the engine out of the engine compartment so that the rear cover plate is not bent or other components damaged. Install the engine on a workstand.

Installation

1. Attach the engine lifting brackets and sling (Fig. 5). Remove the engine from the workstand.
2. Lower the engine carefully into the engine compartment. Make sure the dowels in the block are through the rear cover plate, then engage the holes in the flywheel housing.

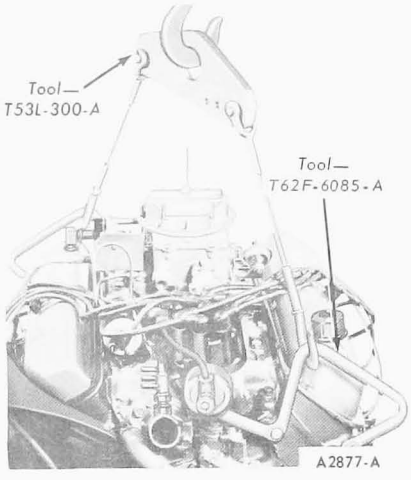

FIG. 5 Typical Engine Lifting Brackets and Sling

On a vehicle with manual transmission, start the transmission main drive shaft into the clutch disc. It may be necessary to adjust the position of the transmission in relation to the engine if the input shaft will not enter the clutch disc. **If the engine hangs up after the shaft enters, turn the crankshaft slowly (transmission in gear) until the shaft splines mesh with the clutch disc splines.**

3. Install the flywheel housing upper bolts.
4. Install the engine support insulator-to-bracket attaching nuts. Disconnect the engine lifting sling and remove the lifting brackets.
5. Raise the front of the vehicle. Connect both exhaust manifolds to the muffler inlet pipes. Tighten the nuts to specifications.
6. Position and install the starter and the starter cable.

Install the remaining flywheel housing-to-engine bolts.

On a vehicle with automatic transmission, install the converter-to-flywheel attaching bolts. Install the converter inspection plate.

7. Remove the support from the transmission and lower the vehicle.
8. Connect the wiring harness to the left valve rocker arm cover and connect the coil wire.
9. Connect the water temperature sending unit wire.
10. Connect the bellcrank to the intake manifold. Connect the transmission shift rod and install the retracting spring. Connect the accelerator rod.
11. Remove the plug from the fuel tank line and connect the fuel line and the oil pressure sending unit wire.
12. Install the pulley, belt, spacer and fan. Position the fan shroud over the fan.
13. Position the alternator and install the alternator bolts. Connect the alternator and the battery ground cables. Adjust the belt tension to specifications.
14. Install the radiator. Connect the radiator upper and lower hoses. Connect the transmission oil cooler lines if so equipped. Install the fan shroud.
15. Connect the heater hose at the water pump. Fill and bleed the cooling system. Fill the crankcase with the proper grade and quantity of oil.
16. Operate the engine at fast idle and check all gaskets and hose connections for leaks.
17. Install the air cleaner and intake duct assembly including the crankcase ventilation hose.

ECONOLINE

Removal

1. Remove engine cover.
2. Remove right front seat bolts and nuts and position the seat out of the way.
3. Drain the cooling system.
4. Remove air cleaner and intake duct assembly, including the crankcase ventilation hose.
5. Disconnect battery and alternator ground cables at the cylinder block.
6. Remove oil filler tube at dash panel and disconnect at the rocker arm cover.
7. Disconnect the radiator upper and lower hoses at the radiator and automatic transmission cooler lines (if so equipped).
8. Disconnect radiator attaching bolts and remove radiator.
9. Disconnect heater hoses at engine and position out of way.
10. Remove fan, spacer, pulley and drive belt.
11. Disconnect accelerator linkage at accelerator shaft on left cylinder head. Disconnect automatic transmission kickdown rod at the carburetor and vacuum line at the intake manifold (if so equipped).
12. Disconnect engine wire harness from left rocker arm cover and position out of way.
13. Remove upper nut attaching right exhaust manifolds to muffler inlet pipe.
14. Raise vehicle on hoist.
15. Drain crankcase and remove oil filter.

16. Disconnect fuel line, tank to pump, at the fuel pump.
17. Disconnect oil dipstick tube bracket from exhaust manifold and oil pan.
18. On manual-shift transmissions, remove bolts attaching equalizer arm bracket to cylinder block and clutch housing (this includes clutch linkage disconnection and retracting spring). Remove bracket.
19. Disconnect starter cable at starter and remove starter.
20. On a vehicle with manual-shift transmission, disconnect drive shaft at rear axle and remove drive shaft. Install plug in transmission end.

On vehicle with automatic transmission, disconnect drive shaft at companion flange.

21. Disconnect speedometer cable and transmission linkage at transmission.
22. Position a transmission jack under transmission. Raise transmission and remove bolts attaching crossmember to chassis. Lower transmission slightly and remove bolt and nut attaching engine rear support to crossmember. Remove crossmember.
23. On a vehicle with manual-shift transmission, remove bolts attaching transmission to clutch housing. Remove transmission.
24. On a vehicle with automatic transmission, remove lower front cover from converter housing. Remove transmission dipstick tube and drain transmission. Install plastic plug in transmission oil pan.

Remove nuts attaching transmission converter to flywheel. Disconnect oil cooler lines and vacuum lines at transmission. Remove remaining bolts fastening transmission to engine. Remove transmission.

25. Position engine support bar tool (T65E-6000-J) to engine and chassis.
26. Disconnect muffler inlet pipes at exhaust manifolds.
27. Remove engine front support attaching nuts and washers.
28. Remove bellcrank bolt from side of cylinder block and position bellcrank assembly to the side.
29. Lower the vehicle.
30. Remove bolts fastening alternator and adjusting arm to the cylinder block and water pump and position out of the way.
31. Remove carburetor air horn stud. Disconnect fuel line, pump to carburetor, at fuel pump.
32. Install engine lifting hooks and chain and remove through side door.
33. On manual-shift transmission, remove bolts fastening adapter plate to clutch housing. remove clutch housing from cylinder block.

Installation

1. On manual-shift transmission, position clutch housing to cylinder block and install attaching bolts. Install adapter plate to clutch housing.
2. Connect fuel line, pump to carburetor, at fuel pump.
3. Position alternator and adjusting arm to cylinder block and water pump. Install and tighten bolts to specification.
4. Lift engine and position to chassis and supporting tool.
5. Raise vehicle on hoist.
6. Install engine front support attaching nuts and washers. Tighten to specifications.
7. On a vehicle with automatic transmission, position bellcrank assembly to cylinder block and install attaching bolt. Tighten to specifications.

Position transmission to engine and install attaching bolts. Tighten to specification.

8. On a vehicle with manual-shift transmission, position transmission to clutch housing and install the attaching bolt. Tighten to specifications.
9. Remove engine support bar (Tool T65E-6000-J).
10. Position engine rear support crossmember to chassis and install attaching bolts. Position transmission with engine rear support attached to crossmember. Install bolt and nut. Tighten all bolts and nuts to specifications. Remove the jack.
11. On a vehicle with automatic transmission, install and tighten converter-to-flywheel attaching nuts. Connect oil cooler and vacuum lines at transmission. Install transmission dipstick tube in pan. Install dipstick tube and vacuum line retaining bracket bolt to cylinder block.
12. Connect transmission shift linkages and speedometer cable.
13. On a vehicle with automatic transmission, connect drive shaft to transmission companion flange.

On a vehicle with manual-shift transmission, remove plug from transmission and install drive shaft yoke into transmission. Connect rear end of drive shaft at rear axle.

14. Install starter and connect cable to starter.
15. Install the muffler inlet pipe attaching bolts and nuts (except upper nut on right exhaust manifold).
16. On a manual-shift transmission, install the bolts connecting equalizer arm bracket to cylinder block and clutch housing (this includes clutch linkage connection and retracting spring).
17. Install the oil filter.
18. Install oil dipstick tube bracket to oil pan and exhaust manifold.
19. Connect fuel line, tank to pump, at pump.
20. Lower the vehicle.
21. Install the upper nut attaching right exhaust manifold to muffler inlet pipe.
22. Connect engine wire harness at left rocker arm cover. Connect battery and alternator ground cables at cylinder block.
23. Connect automatic transmission vacuum line at intake manifold and transmission kickdown rod at carburetor (if so equipped). Connect accelerator linkage to accelerator shaft on left cylinder head.
24. Install drive belt, pulley, spacer and fan, then tighten belt to specification.
25. Connect heater hoses at engine.
26. Position radiator and install attaching bolts. Connect radiator upper and lower hoses and automatic transmission cooler lines (if so equipped).
27. Install oil filler tube by connecting to left rocker arm cover and dash panel.
28. Install air cleaner and intake duct assembly, including the crankcase ventilation hose.
29. Fill and bleed cooling system.
30. Fill crankcase and automatic transmission (if so equipped).
31. Install engine cover and right front seat.
32. Operate the engine at fast idle and check all hose and gasket connections for leaks.

ENGINE FRONT SUPPORTS

The front supports are located on each side of the cylinder block (Figs. 6 and 7). The procedures given apply to either a right or left installation.

F-100

Removal

1. Remove the bolts attaching the fan shroud to the radiator and position the shroud over the fan.
2. Remove the nut and washer attaching the support insulator to the chassis bracket.
3. Raise the engine.

4. Remove the bolts and lock washers attaching the support insulator to the cylinder block and remove the insulator.

Installation

1. Position the support insulator to the cylinder block and install the attaching bolts and lock washers loosely.
2. Carefully lower the engine, guiding the support insulator stud into the support bracket. Tighten the insulator-to-engine bolts to specifications.
3. Install the insulator-to-chassis bracket nut and washer. Tighten the nut to specifications.
4. Install the fan shroud attaching bolts.

BRONCO AND ECONOLINE

Removal

1. Raise the vehicle on a hoist.
2. Remove one nut attaching the engine support insulator to the support bracket.
3. Position transmission jack beneath the front of the oil pan. Raise the engine only enough to clear the support insulator bolt at the support bracket.
4. Remove the bolts holding the support insulator to the block, and remove the support insulator.

Installation

1. Position the support insulator on the block and install the attaching bolts. Tighten the bolts to specification.
2. Carefully lower the engine, guiding the support insulator bolt into the support bracket.
3. Install the nut attaching the engine support insulator to the support bracket. Tighten the nut to specifications.
4. Lower the vehicle.

ENGINE REAR SUPPORTS

The procedures given apply to either a right or left support Bronco only and F-100 and Econoline center mount (Figs. 8 and 9).

F-100

Removal

1. Remove the support insulator-to-crossmember attaching bolt and lock nut.
2. Remove the support insulator-to-transmission extension housing bolts and lock washers.
3. Raise the transmission with a floor jack. Remove the support insulator and retainer.

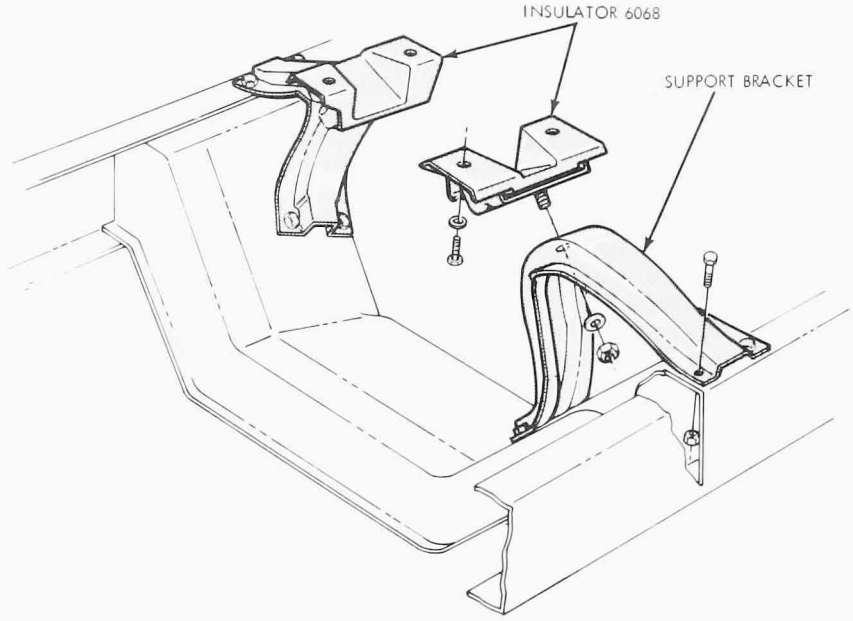

FIG. 6 Engine Front Supports—F-100

Installation

1. Position the support insulator and retainer on the transmission extension housing.
2. Install the support insulator-to-transmission extension housing bolts and lock washers. Torque the bolts to specifications. Lower the transmission.
3. Install the support insulator-to-crossmember attaching bolt and lock nut. Tighten the nut to specifications.

Check to see that the retainer does not contact the portion of the insulator which is attached to the crossmember.

BRONCO

Removal

1. Raise the vehicle on a hoist.
2. Remove the skid plate, if so equipped. Remove the cotter pins, the attaching nuts and the attaching bolts of both support insulators, even though only one is to be replaced. Remove the washers, the retaining plates and the lower support insulators.
3. Position a transmission jack beneath the transmission. Raise the transmission, remove the spacer and the upper support insulator of the assembly to be replaced.

Installation

1. Position the upper support insulator and the spacer on the assembly to be replaced and lower the transmission.
2. Position the lower support insulators, retaining plates and washers, then install the attaching bolts and nuts. Tighten the nuts to specifications and install the cotter keys.
3. Install the skid plate, if so equipped.
4. Lower the vehicle.

ECONOLINE

Removal

1. Raise the vehicle on a hoist.
2. Remove the insulator support bolt and nut securing the rear insulator support to the frame.
3. Raise the transmission with a jack so that the insulator support clears the frame.
4. Remove the insulator support bolt and nut securing the rear insulator support to the transmission, then remove the insulator and retainer.

Installation

1. Position the insulator support and retainer, then install the bolts securing the insulator support to the transmission. Tighten the bolts to specifications.
2. Lower the jack supporting the transmission and align the insulator support bolt hole with the hole in the frame assembly.
3. Install the bolt and nut securing the insulator support to the frame. Tighten to specification.
4. Lower the vehicle.

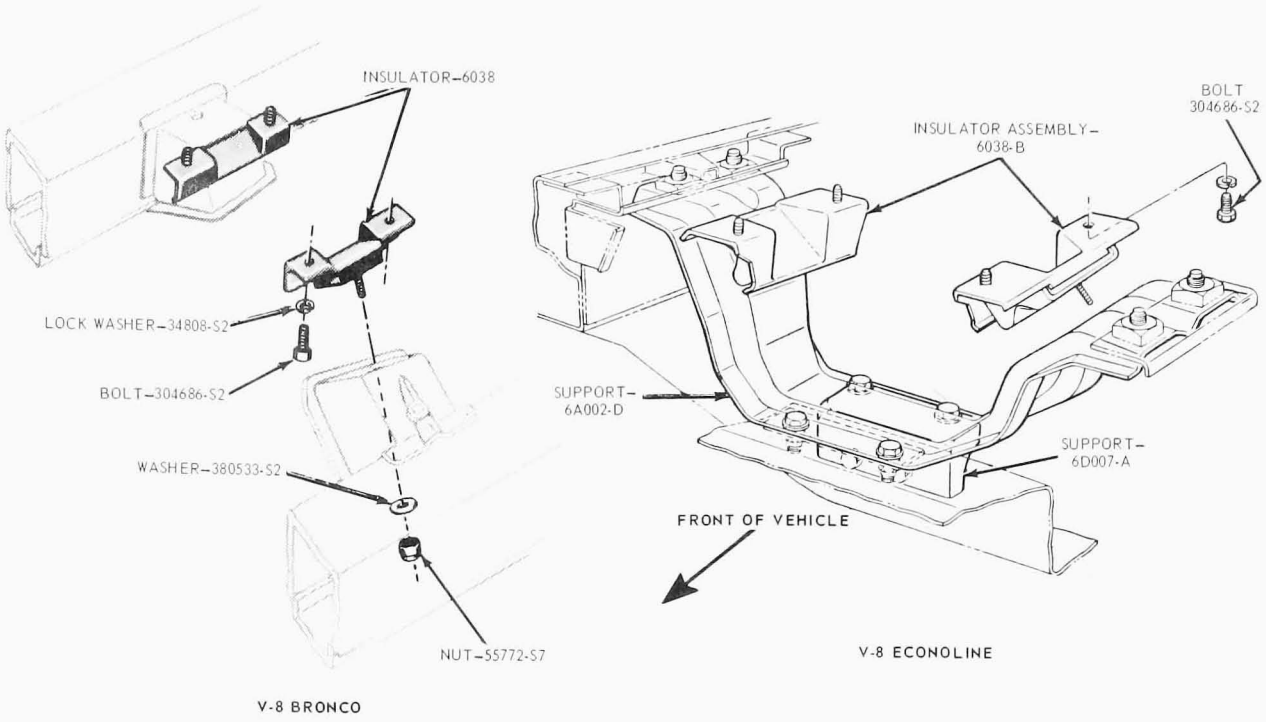

FIG. 7 Engine Front Supports—Bronco and Econoline

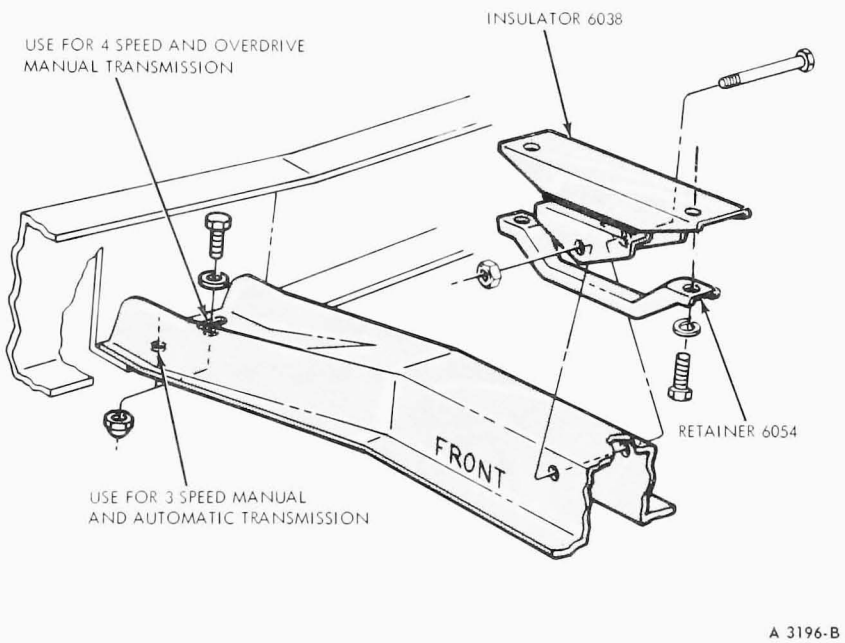

FIG. 8 Engine Rear Support—F-100

CRANKCASE VENTILATION SYSTEM

The crankcase ventilation system components for the various applications are shown in Fig. 10. **Any modification of the system prior to the first sale and registration of the vehicle is subject to Federal (U.S.A.) law and to the penalties under the laws of some states thereafter.**

F-100 AND BRONCO

Removal

1. Disconnect the crankcase vent rear hose from the air cleaner. Pull the hose and elbow out of the grommet in the valve rocker arm cover. Remove the elbow from the vent hose.
2. Remove the air cleaner and intake duct assembly.
3. Disconnect the crankcase vent front hose from the carburetor spacer and the regulator valve in the oil filler cap.
4. Remove the cam-lock oil filler cap

from the valve rocker arm cover. Pull the regulator valve out of the grommet in the oil filler cap.

Installation

1. Insert the regulator valve into the grommet in the oil filler cap. Install the oil filler cap in the valve rocker arm cover and turn the cap to lock it into position.
2. Connect the crankcase vent front hose to the regulator valve and the carburetor spacer.
3. Install the air cleaner and intake duct assembly.
4. Insert the elbow into the grommet in the valve rocker arm cover. Connect the crankcase vent rear hose to the elbow and the air cleaner.
5. Start the engine and check for leaks.

ECONOLINE

Removal

1. Disconnect the crankcase vent front hose from the air cleaner and the oil filler tube.
2. Remove the air cleaner and intake duct assembly.
3. Disconnect the crankcase vent rear hose from the carburetor spacer. Pull the hose and regulator valve out of the grommet in the valve rocker arm cover. Remove the regulator valve from the vent hose.

Installation

1. Insert the regulator valve into the grommet in the valve rocker arm cover. Connect the crankcase vent rear hose to the regulator valve and the carburetor spacer.
2. Install the air cleaner and intake duct assembly.
3. Connect the crankcase vent front hose to the air cleaner and the oil filler tube.
4. Start the engine and check for leaks.

VALVE ROCKER ARM COVER AND ROCKER ARM

F-100 AND BRONCO

Removal

1. Remove air cleaner and intake duct assembly, including the closed crankcase ventilation hoses.
2. Remove the crankcase ventilation regulator valve from the oil filler cap in the left rocker arm cover.
3. Disconnect the spark plug wires from the spark plug by grasping, twisting and pulling the moulded cap by hand only. Remove the wires from the bracket on the valve rocker arm cover(s) and position out of the way.
4. Remove rocker arm cover(s).
5. Remove the valve rocker arm stud nut, fulcrum seat and rocker arm. If removal of the rocker arm stud is necessary, refer to the procedure under Cylinder Head Repairs in Part 21-01.

Installation

The valve rocker arm assembly sequence is shown in Fig. 11.

1. Inspect the rocker arm stud nut for the conditions shown in Fig. 4. If there are small fractures in the chamfered area or the chamfer is more than 1/16 inch wide, replace the stud nut.
2. Apply Lubriplate or equivalent to the top of the valve stem, the fulcrum seat and socket.
3. Install the valve rocker arm, fulcrum seat and stud nut. Adjust the valve clearance following the procedure under Valve Clearance Adjustment.
4. Clean and inspect gasket surfaces. Inspect the gasket sealing surface for damages and distortion due to overtightening of the bolt. Repair and straighten as required.
5. Place the new gaskets in the covers making sure that the tabs of the gasket engage the notches provided in the cover. Position the cover(s) on

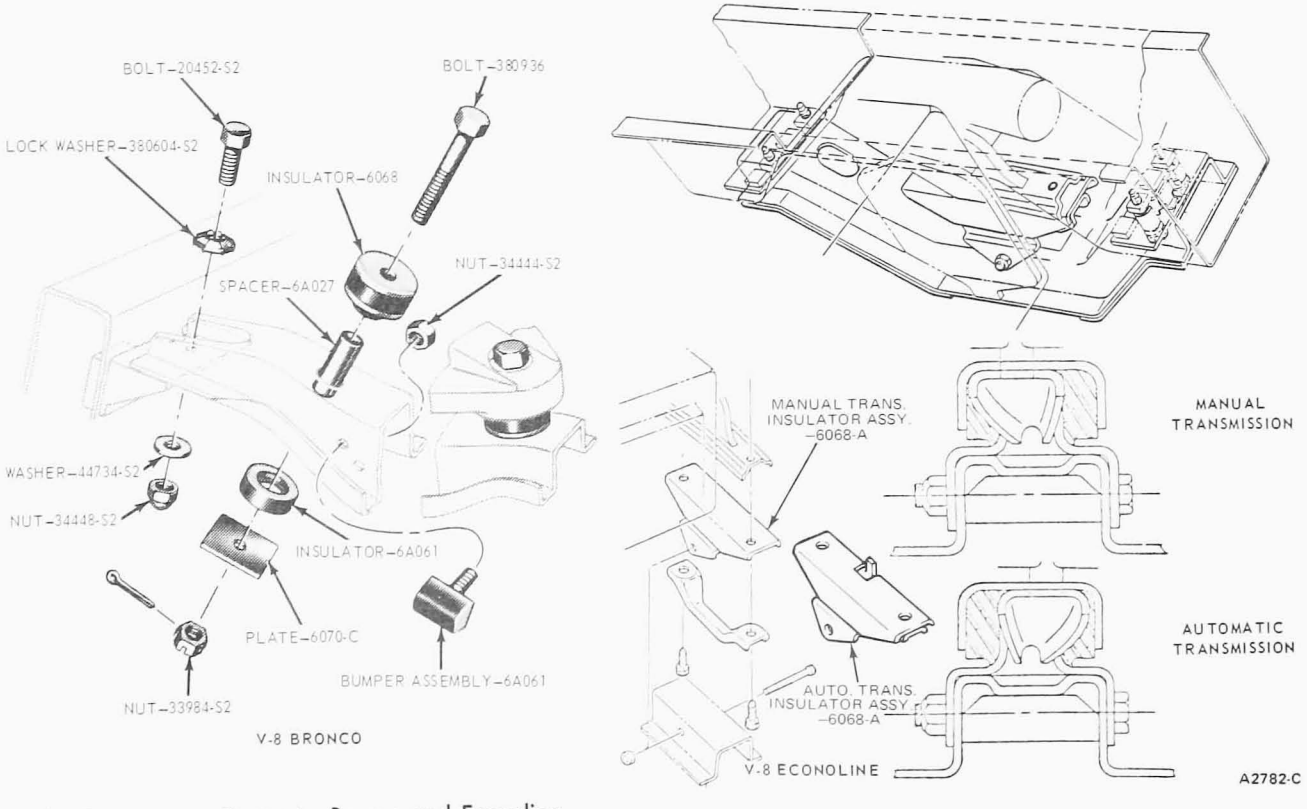

FIG. 9 Engine Rear Support—Bronco and Econoline

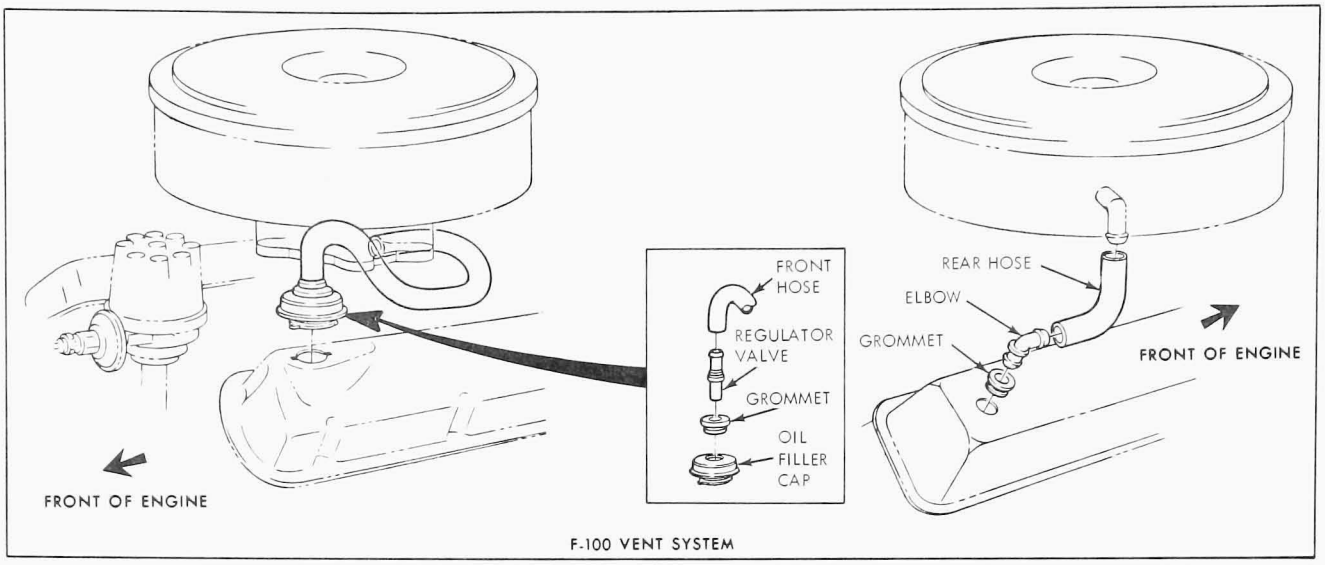
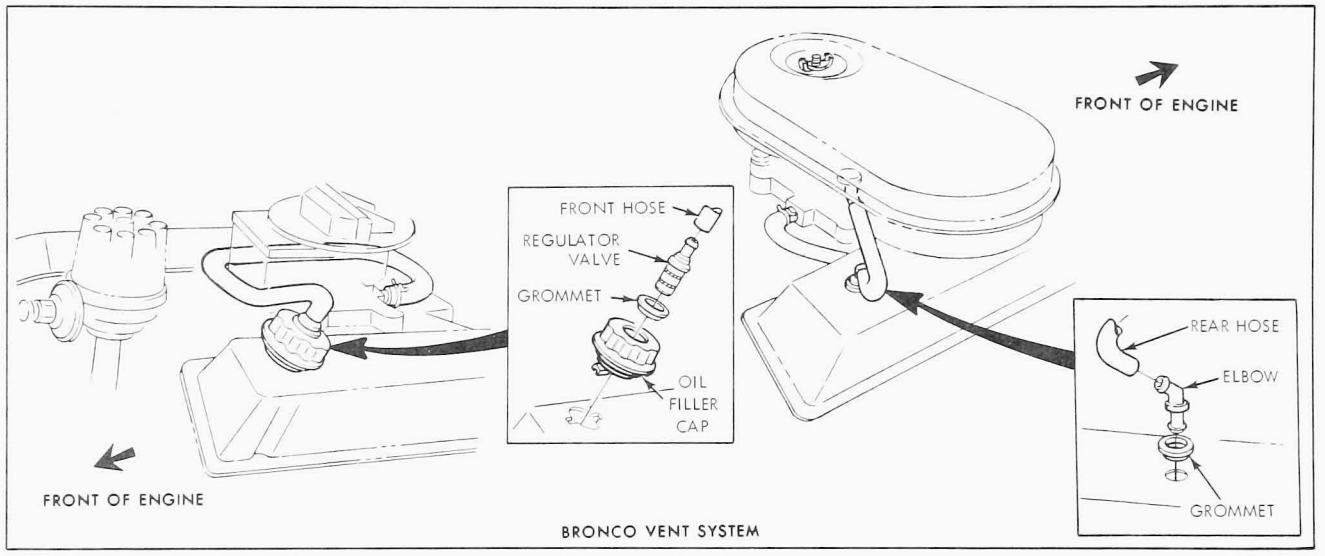
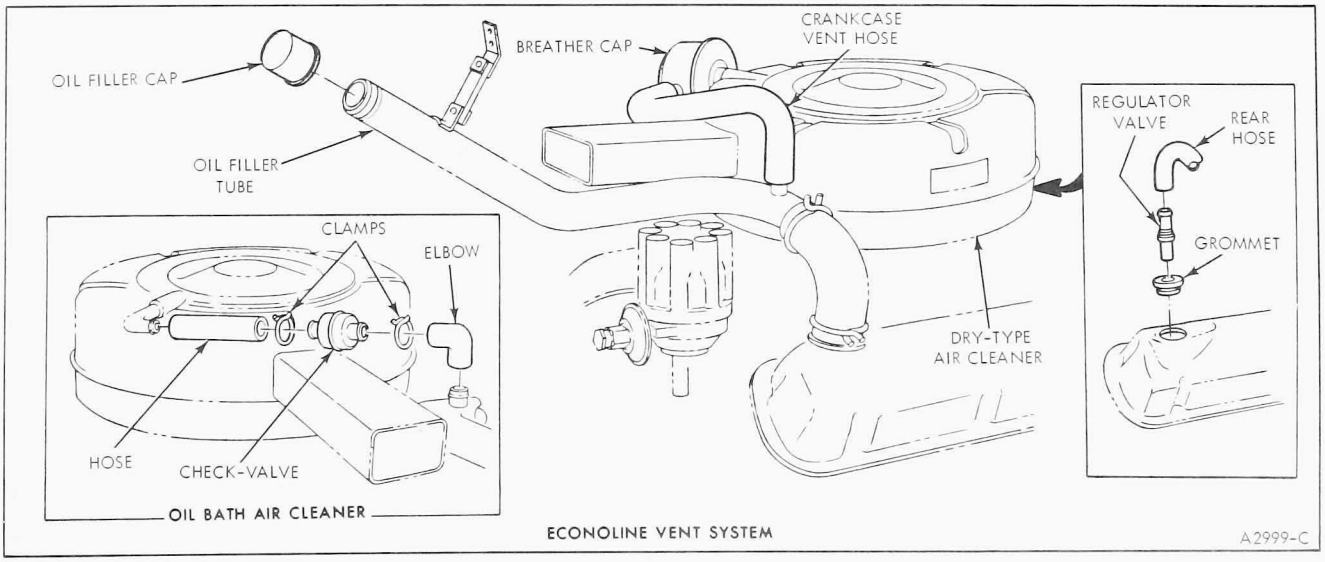


F-100 VENT SYSTEM



BRONCO VENT SYSTEM



ECONOLINE VENT SYSTEM

A2999-C

FIG. 10 302 CID Crankcase Ventilation Systems

the cylinder head(s). Make sure the gasket seats evenly all around the head. Install the bolts and tighten to specifications. Two minutes later, tighten the bolts to the same specifications.

6. Insert the spark plug wires in the bracket on the rocker arm cover(s) and connect the wires to the spark plugs.
7. Install the crankcase ventilation regulator valve into the oil filler cap in the rocker arm cover.
8. Install air cleaner and intake duct assembly, including the crankcase ventilation hoses.

ECONOLINE

Removal

1. Remove air cleaner and intake duct assembly, including the crankcase ventilation hoses.
2. Disconnect oil filler pipe hose from left rocker arm cover.
3. Remove the crankcase ventilation regulator valve from the right rocker arm cover.
4. Disconnect the spark plug wires from the spark plugs by grasping, twisting and pulling the moulded cap by hand only. Remove the wires from the bracket on the valve rocker arm cover(s) and position out of the way.
5. Remove rocker arm cover(s).
6. Remove the valve rocker arm stud nut, fulcrum seat and rocker arm. If removal of the rocker arm stud is necessary, refer to the procedure under Cylinder Head Repairs in Part 21-01.

Installation

1. Inspect the rocker arm stud nut for the conditions shown in Fig. 4. If there are small fractures in the chamfered area or the chamfer is more than 1/16 inch wide, replace the stud nut.
2. Apply Lubriplate or equivalent to the top of the valve stem, the fulcrum seat and socket.
3. Install the valve rocker arm, fulcrum seat and stud nut. Adjust the valve clearance following the procedure under Valve Clearance Adjustment.
4. Clean and inspect gasket surfaces. Inspect the gasket sealing surface for damages and distortion due to overtightening of the bolt. Repair and straighten as required. Place the new gaskets in the covers making sure that the tabs of the gasket engage the notches provided in the cover.
5. Position the cover(s) on the cylinder head(s). Make sure the gasket seats evenly all around the head. Install the bolts and tighten to specifications. Two minutes later, tighten the bolts to the same specifications.
6. Insert the spark plug wires in the bracket on the rocker arm cover(s) and connect the wires at the spark plugs.
7. Install the crankcase ventilation regulator valve into the right rocker arm cover.
8. Connect the oil filler pipe hose to the left rocker arm cover.
9. Install the air cleaner and intake duct assembly, including the crankcase ventilation hoses.

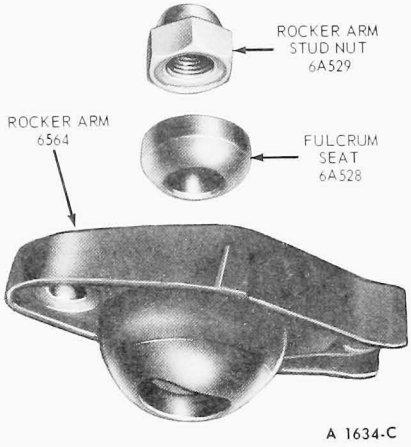


FIG. 11 Valve Rocker Arm Assembly

INTAKE MANIFOLD

The intake manifold assembly is shown in Fig. 12.

Removal

1. Drain the cooling system. Remove the air cleaner and intake duct assembly, including the crankcase ventilation hose.
2. Disconnect the accelerator rod and choke cable from the carburetor. Remove the accelerator retracting spring. Disconnect the automatic transmission kickdown rod at the carburetor (if so equipped).
3. Disconnect the high-tension lead and wires from the coil.
4. Disconnect the spark plug wires from the spark plugs by grasping, twisting and pulling the moulded cap by hand only. Remove the wires from the harness brackets on the valve rocker arm covers. Remove the distributor cap and spark plug wires as an assembly.

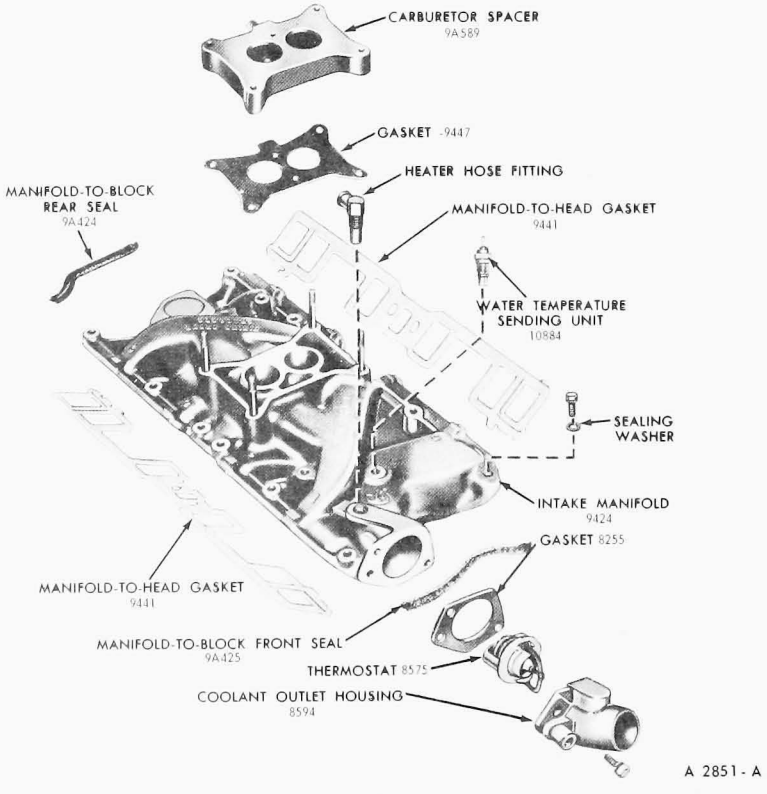

FIG. 12 Intake Manifold Assembly

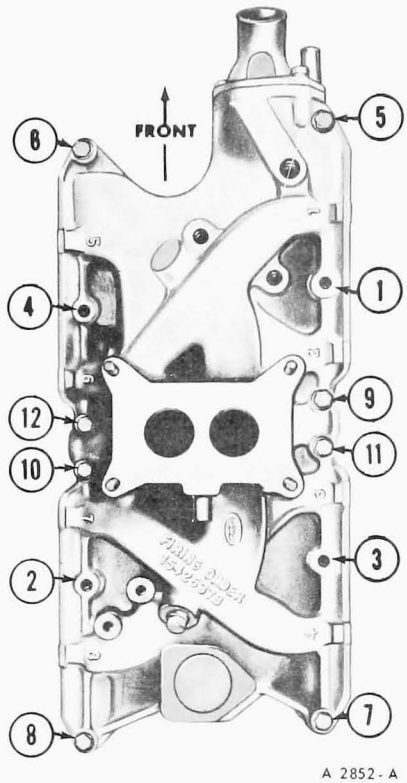
5. Remove the carburetor fuel inlet line.
6. Disconnect the distributor vacuum hoses from the distributor. Remove the distributor hold down bolt and remove the distributor.
7. Disconnect the radiator upper hose from the coolant outlet housing, and the water temperature sending unit wire at the sending unit. Remove the heater hose from the intake manifold.
8. Loosen the clamp on the water pump by-pass hose at the coolant outlet housing and slide the hose off the outlet housing.
9. Disconnect the crankcase vent hose at the valve rocker arm cover.
10. Remove the intake manifold and carburetor as an assembly. **It may be necessary to pry the intake manifold away from the cylinder heads. Remove the intake manifold gaskets and seals. Discard the intake manifold attaching bolt sealing washers.**
11. If the manifold assembly is to be disassembled, identify all vacuum hoses before disconnecting them. Remove the coolant outlet housing gasket and thermostat. Remove the ignition coil and engine identification tag, temperature sending unit, carburetor, spacer, gasket, vacuum fitting, accelerator retracting spring bracket and choke cable bracket.

Installation

1. If the intake manifold assembly was disassembled, install the temperature sending unit (threads coated with electrical conductive sealer), ignition coil and engine identification tag, carburetor, spacer, gaskets, vacuum fitting, accelerator retracting spring bracket and choke cable bracket. Position the thermostat in the coolant outlet housing. Coat the thermostat gasket with water-resistant sealer and position it on the coolant outlet housing. Install the coolant outlet housing. Connect all vacuum hoses, following the instructions given in Part 23-01.
2. Clean the mating surfaces of the intake manifold, cylinder heads and cylinder block. Use a suitable solvent to remove all traces of oil. Coat the cylinder block seal surfaces with contact adhesive sealer.
3. Position new seals on the cylinder block and new gaskets on the cylinder heads with the gaskets interlocked with the seal tabs. Be sure the holes in the gaskets are aligned with the holes in the cylinder heads.



A 2852-A

FIG. 13 Intake Manifold Bolts Tightening Sequence

Apply non-hardening sealer at the four junction points of the seals and gaskets.

4. Carefully lower the intake manifold into position on the cylinder block and cylinder heads. **After the intake manifold is in place, run a finger around the seal area to make sure the seals are in place. If the seals are not in place, remove the intake manifold and position the seals.**
5. Be sure the holes in the manifold gaskets and manifold are in alignment. Install the intake manifold attaching nuts and bolts. Tighten the nuts and bolts in two steps (Fig. 13). Tighten all nuts and bolts in sequence to specifications.

After completing the remaining assembly steps, operate the engine until it reaches normal operating temperature, then retighten the manifold nuts and bolts in sequence to specifications.

6. Install the water pump by-pass hose on the coolant outlet housing. Slide the clamp into position and tighten the clamp.
7. Connect the radiator upper hose. Install the heater hose and connect the hose to the intake manifold.
8. Install the carburetor fuel inlet line.
9. Rotate the crankshaft damper until the No. 1 piston is on TDC at the end of the compression stroke. Position the distributor in the block with the rotor at the No. 1 firing position and the points just open. Install the hold-down clamp.
10. Install the distributor cap. Position the spark plug wires in the harness brackets on the valve rocker arm covers and connect the wires to the plugs.
11. Connect crankcase vent hose. Connect the high-tension lead and coil wires.
12. Connect the accelerator rod and retracting spring. Connect the choke cable. Connect the automatic transmission kickdown rod at the carburetor (if so equipped).
13. Fill and bleed the cooling system.
14. Start the engine and check and adjust the ignition timing. Connect the distributor vacuum hoses to the distributor.
15. Operate the engine at fast idle and check all hose connections and gaskets for leaks. Operate the engine until engine temperatures have stabilized and adjust the engine idle speed and idle fuel mixture. Retighten the intake manifold bolts to specifications.
16. Adjust the transmission throttle linkage. Install the air cleaner and intake duct assembly, including the closed crankcase ventilation hose.

EXHAUST MANIFOLDS

Removal

1. Remove air cleaner and intake duct assembly, including the crankcase ventilation hose.
2. Remove bolts attaching the air cleaner inlet duct (Bronco and F-100 vehicles only) and oil dipstick tube bracket on right exhaust manifold.
3. Disconnect exhaust manifold(s) from inlet pipe(s).
4. Remove the attaching bolts and flat washers, then remove the exhaust manifold.

Installation

1. Clean the mating surfaces of the exhaust manifold(s) and cylinder head(s). Clean the mounting flange of the exhaust manifold(s) and muffler inlet pipe(s).
2. Apply graphite grease to the mating surface of the exhaust manifold(s).
3. Position the exhaust manifold(s) on the cylinder head(s) and install the attaching bolts and flat washers. Working from the center to the ends, tighten the bolts to specifications.
4. Place a new gasket(s) on the muffler inlet pipe(s). Position the muffler

inlet pipe(s) into the manifold(s). Install and tighten the attaching nuts to specifications.
5. Position the air cleaner inlet duct (Bronco and F-100 vehicles only) and the oil dipstick tube bracket on the right exhaust manifold. Install and tighten attaching bolts to specifications.
6. Install air cleaner and intake duct assembly, including the crankcase ventilation hose.

CYLINDER HEADS

If a cylinder head is to be replaced, follow the procedures under Cylinder Head Disassembly and Assembly in this Part, and transfer all valves, springs, spark plugs, etc., to the new cylinder head. Clean and inspect all parts, reface the valves (refer to Part 21-01) and check all assembly clearances before assembling the new or used parts to the new cylinder head.

Removal

1. Remove the intake manifold and carburetor as an assembly, following the procedure under Intake Manifold Removal.
2. Remove the rocker arm cover(s).
3. If the right cylinder head is to be removed, loosen the alternator adjusting arm bolt and remove the alternator mounting bracket bolt and spacer. Swing the alternator down and out of the way. Remove the ignition coil (Bronco and Econoline) and air cleaner inlet duct from the right cylinder head assembly.

If the left cylinder head is being removed, remove the bolts fastening the accelerator shaft assembly at the front of the cylinder head.

4. Disconnect the exhaust manifold(s) from the muffler inlet pipe(s).
5. Loosen the rocker arm stud nuts so that the rocker arms can be rotated to the side. Remove the push rods in sequence (Fig. 14) so that they may be installed in their original positions.
6. Remove the exhaust valve stem caps.
7. Install the cylinder head holding fixtures (Fig. 15). Remove the cylinder head attaching bolts and lift the cylinder head off the block. Remove and discard the cylinder head gasket.

Installation

1. Clean the cylinder head, intake manifold, valve rocker arm cover and cylinder head gasket surfaces. If the cylinder head was removed for a cylinder head gasket replacement, check the flatness of the cylinder head and block gasket surfaces.
2. On the 302 V-8 engine, a specially treated composition gasket is used. **Do not apply sealer to a composition gasket. Position the new cylinder head gasket over the cylinder dowels on the block. Position the cylinder head on the block and install the attaching bolts. Remove the holding fixtures.**
3. The cylinder head bolts are tightened in three progressive steps. Tighten all the bolts in sequence (Fig. 16) to specifications. When cylinder head bolts have been tightened following this procedure, it is not necessary to retighten the bolts after extended operation. However, the bolts may be checked and retightened if desired.
4. Clean the push rods in a suitable solvent. Blow out the oil passage in the push rod with compressed air. Check the ends of the push rods for nicks, grooves, roughness or excessive wear. Visually check the push rods for straightness or check push rod runout with a dial indicator. If runout exceeds the maximum limit at any point, discard the rod. **Do not attempt to straighten push rods.**
5. Lubricate the end of the push rods with Lubriplate or equivalent and install them in their original positions. Apply Lubriplate or equivalent to the valve stem tips. Install the exhaust valve stem cap.
6. Lubricate the rocker arms and fulcrum seats with Lubriplate or equialent, then install the rocker arms. Perform a valve clearance adjustment as outlined under Valve Clearance Adjustment.
7. Position a new gasket(s) on the muffler inlet pipe(s). Connect the exhaust manifold(s) at the muffler inlet pipe(s). Tighten the nuts to specifications.
8. If the right cylinder head was removed, swing the alternator into position and install the alternator attaching bolt and spacer, ignition coil (Bronco and Econoline) and air cleaner inlet duct on the right cylinder head. Adjust the drive belt tension to specifications.

If the left cylinder head was removed, install the accelerator shaft assembly at the front of the cylinder head.

9. Clean the valve rocker arm cover and cylinder head gasket surfaces. Place the new gaskets in the covers making sure that the tabs of the gasket engage the notches provided in the cover. Install the valve rocker arm cover(s).
10. Install the intake manifold and related parts, following the procedure under Intake Manifold Installation.

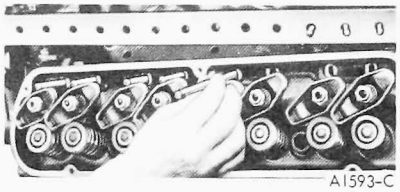


FIG. 14 Removing Valve Push Rods

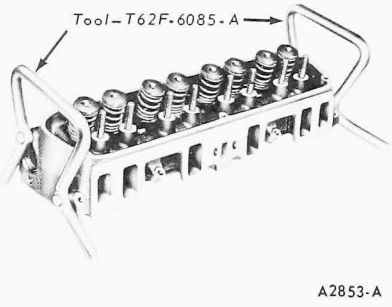

FIG. 15 Cylinder Head Holding Fixtures

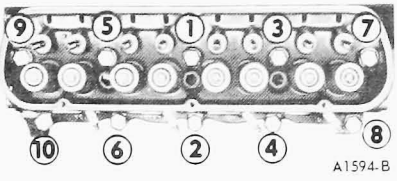

FIG. 16 Cylinder Head Bolt Tightening Sequence

VALVE SPRING, RETAINER AND STEM SEAL

Removal

Broken valve springs or damaged valve stem seals and retainers may be replaced without removing the cylinder head, provided damage to the valve or valve seat has not occured.

1. Refer to Valve Rocker Arm Cover in this section for the cover removal and installation.
2. Remove the applicable spark plug and bring the piston to the top of the bore to prevent accidental loss of the valve into the cylinder.
3. Remove the valve rocker arm stud

nuts, fulcrum seats, valve rocker arms and push rods from the applicable cylinder. Remove the exhaust valve stem cap.

4. Install an air line with an adapter in the spark plug hole and apply air pressure to the cylinder. Failure of the air pressure to hold the valve(s) in the closed position is an indication of valve seat damage and requires removal of the cylinder head.
5. Install the stud nut and position the compressor tool as shown in Fig. 17. Compress the valve spring and remove the retainer locks, spring retainer, sleeve and valve spring.
6. Remove and discard the valve stem seal (Fig. 18).
7. **If air pressure has forced the piston to the bottom of the cylinder, any removal of air pressure will allow the valve(s) to fall into the cylinder. A rubber band, tape or string wrapped around the end of the valve stem will prevent this condition and will still allow enough travel to check the valve for binds.**
8. Inspect the valve stem for damage. Rotate the valve and check the valve stem tip for eccentric movement during rotation. Move the valve up and down through normal travel in the valve guide and check the stem for binds. **If the valve has been damaged, it will be necessary to remove the cylinder head for repairs as outlined in Part 21-01.**

Installation

1. If the condition of the valve proved satisfactory, lubricate the valve stem with heavy engine oil SE. Hold the valve in the closed position and apply air pressure within the cylinder.
2. Install a new valve stem seal (Fig. 18). Place the spring in position over the valve and install the valve spring retainer and sleeve. Compress the valve spring and install the valve spring retainer locks. Remove the compressor tool and stud nut.
3. Lubricate the push rod ends with Lubriplate or equivalent and install the push rod. Apply Lubriplate or equivalent to the tip of the valve stem. Install the exhaust valve stem cap.
4. Apply lubriplate or equivalent to the rocker arms and fulcrum seats. Inspect the stud nuts for conditions shown in Fig. 4. Install the valve rocker arms, fulcrum seats and stud nuts. Adjust the valve clearance following the procedure under Valve Clearance Adjustment.
5. Turn off the air and remove the air line and adapter. Install the spark plug and connect the spark plug wire.
6. Clean and install the rocker arm cover.

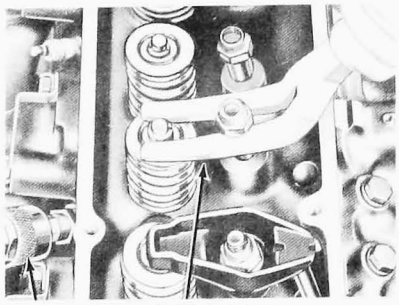

FIG. 17 Compressing Valve Spring—In Chassis

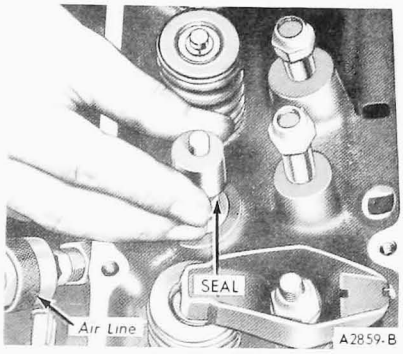

FIG. 18 Removing or Installing Valve Stem Seal

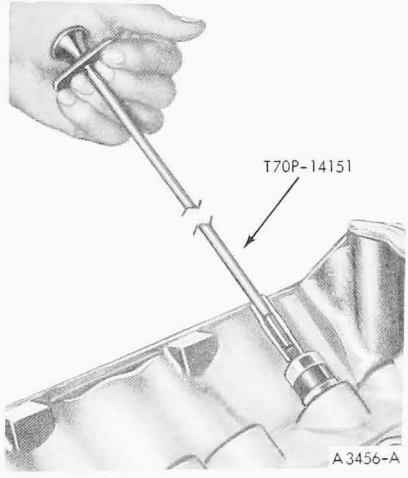

FIG. 19 Removing Valve Lifter

VALVE LIFTER

Before replacing a hydraulic valve lifter for noisy operation, be sure the noise is not caused by improperly adjusted valve to rocker arm clearance or by worn rocker arms or push rods.

Removal

1. Remove the valve rocker arm cover, then loosen the valve rocker arm stud nut and rotate the rocker arms to the side.
2. Remove the valve push rods in sequence so that they can be installed in their original positions.
3. Using Tool T70P-14151 shown in Fig. 19, remove the valve lifters and place them in a rack so that they can be installed in their original bores.

Installation

Valve lifters and bores are to be lubricated with heavy engine oil SE before installation.

1. Clean and install the valve lifters in the bores from which they were removed, using Tool T70P-14151. If a new lifter(s) is being installed, check the new lifter(s) for a free fit in the bore in which it is to be installed. Lubricate the lifter(s) and bore(s) with heavy engine oil before inserting the lifter.
2. Lubricate the ends of the push rods with Lubriplate or equivalent and install the push rods in their original positions. Apply Lubriplate or equivalent to the valve stem tip.
3. Lubricate the rocker arms and fulcrum seats with Lubriplate or equivalent and position the rocker arms over the push rods. Perform a valve clearance adjustment as outlined in this part.
4. Install the valve rocker arm covers.

WATER PUMP

F-100 AND BRONCO

Removal

1. Drain the cooling system.
2. Remove the bolts securing the fan shroud to the radiator, if so equipped. Position the shroud over the fan.
3. Disconnect the radiator lower hose, heater hose and by-pass hose at the water pump. Remove the drive belts, fan, fan spacer and pulley.

   Remove the fan shroud, if so equipped.
4. Loosen the alternator pivot bolt and bolt attaching the alternator adjusting arm to water pump.
5. Remove the bolts securing the water pump to cylinder front cover. Remove the water pump.

Installation

Before a water pump is reinstalled, check it for damage. If it is damaged, replace it.

1. Remove all gasket material from the mounting surfaces of the cylinder front cover and water pump.
2. Position a new gasket, coated on both sides with sealer, on the cylinder front cover; then, install the pump.
3. Install the attaching bolts and tighten them to specifications.
4. Install the alternator pivot bolt and bolt attaching the alternator adjusting arm to the water pump.
5. Position the fan shroud over the water pump, if so equipped. Install the pulley, spacer and fan. Install and adjust the drive belts to the specified belt tension. Connect the radiator hose, heater hose and by-pass hose.

   Install the fan shroud bolts, if so equipped.
6. Fill and bleed the cooling system. Operate the engine until normal operating temperatures have been reached and check for leaks.

ECONOLINE

Removal

1. Remove the air cleaner and intake duct assembly, including the crankcase ventilation hose.
2. Drain the cooling system.
3. Disconnect the radiator upper hose at the engine and lower hose at the radiator. Remove the radiator attaching bolts and nuts. Remove the radiator.
4. Remove drive belts, fan, spacer and water pump pulley.
5. Loosen the alternator pivot bolt and bolt attaching the alternator adjusting arm to the water pump.
6. Disconnect heater hose and by-pass hose at water pump.
7. Remove the bolts securing the water pump to the cylinder front cover. Remove the water pump.

Installation

Before a water pump is reinstalled, check it for damage. If it is damaged, replace it.

1. Remove all gasket material from the mounting surfaces of the cylinder front cover and water pump.
2. Position a new gasket, coated on both sides with sealer, on the cylinder front cover; then, install the pump.
3. Install the attaching bolts and tighten them to specifications.
4. Connect the heater hose and by-pass hose at the water pump.
5. Tighten the alternator pivot bolt and bolt attaching alternator adjusting arm to the water pump.
6. Install the water pump pulley, spacer and fan drive belts.
7. Install the radiator, connecting lower hose at the radiator and upper hose at the engine.
8. Fill and bleed the cooling system. Operate the engine until normal operating temperatures have been reached and check for leaks.
9. Install the air cleaner and intake duct assembly, including the crankcase ventilation hose.

CYLINDER FRONT COVER AND TIMING CHAIN

Removal

1. On Econoline vehicles, remove the air cleaner and intake duct assembly, including the crankcase ventilation hose.
2. Drain the cooling system and the crankcase.
3. Disconnect the radiator lower hose from the water pump. On Econoline vehicles, remove the radiator upper hose at the engine. Remove the radiator attaching bolts and remove the radiator attaching bolts and remove the radiator.
4. Disconnect the heater hose from the water pump. Slide the water pump by-pass hose clamp toward the water pump.
5. Loosen the alternator pivot bolt and bolt retaining the alternator adjusting arm to the water pump.
6. Remove the bolts securing the fan shroud to the radiator, if so equipped. Position the shroud over the fan, if so equipped. Remove the fan, spacer, pulley and drive belts.

   Remove the fan shroud, if so equipped.
7. Remove the crankshaft pulley from the crankshaft vibration damper.

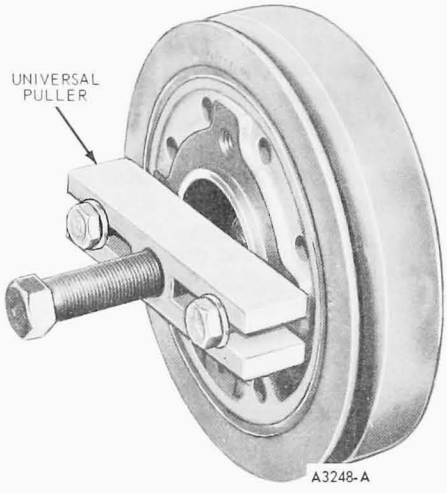

FIG. 20 Crankshaft Vibration Damper Removal—F-100

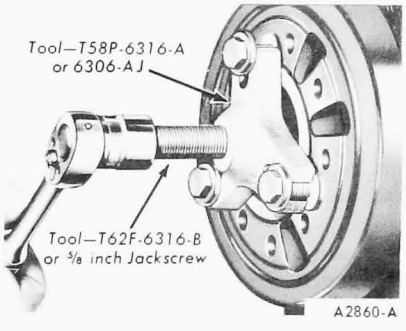

FIG. 21 Crankshaft Vibration Damper Removal—Bronco and Econoline

   Remove the damper attaching bolt and washer. Install the puller on the crankshaft vibration damper (Figs. 20 and 21) and remove the vibration damper.
8. Disconnect the fuel pump outlet line from the fuel pump. Disconnect the vacuum inlet and outlet lines from the vacuum section of the fuel pump (Bronco only). Remove the fuel pump attaching bolts and lay the pump to one side with the flexible fuel lines still attached.
9. Remove the oil level dipstick and bolt fastening the dipstick tube to the exhaust manifold.
10. Remove the oil pan-to-cylinder front cover attaching bolts. Use a thin bladed knife to cut the oil pan gasket flush with the cylinder block face prior to separating the cover from the cylinder block. Remove the cylinder front cover and water pump as an assembly.
11. Discard the cylinder front cover

gasket. Remove the crankshaft front oil slinger.

12. Rotate the crankshaft in a counterclockwise direction (as viewed from the front) to take up the slack on the left side of the chain.
13. Establish a reference point on the block and measure from this point to the chain.
14. Rotate the crankshaft in the opposite direction to take up the slack on the right side of the chain. Force the left side of the chain out with the fingers and measure the distance between the reference point and the chain. The deflection is the difference between the two measurements.

If the deflection exceeds 1/2 inch, replace the timing chain and/or sprockets.

15. Crank the engine until the timing marks on the sprockets are positioned as shown in Fig. 22.
16. Remove the camshaft sprocket capscrew, washers and fuel pump eccentric. Slide both sprockets and the timing chain forward, and remove them as an assembly (Fig. 23).

Installation

1. Position the sprockets and timing chain on the camshaft (Fig. 23). Be sure the timing marks on the sprockets are positioned as shown in Fig. 22.
2. Install the fuel pump eccentric, washers and camshaft sprocket capscrew. Tighten the sprocket capscrew to specifications. Install the crankshaft front oil slinger (Fig. 24).
3. Clean the cylinder front cover, oil pan and the block gasket surfaces. Clean the oil pan gasket surface where the oil pan and front cover fasten.

Install a new oil seal, following procedures under Front Oil Seal Removal and Installation.

4. Lubricate the timing chain and sprockets with heavy engine oil. Apply heavy engine oil SE to the fuel pump eccentric.
5. Coat the gasket surface of the oil pan with sealer, then cut and position the required sections of a new gasket on the oil pan and apply sealer at the corners. Install the pan seal as required.

Coat the gasket surfaces of the block and cover with sealer, and position a new gasket on the block.

6. Position the cylinder front cover on the cylinder block. Use care when installing the cover to avoid seal damage or possible gasket mislocation.

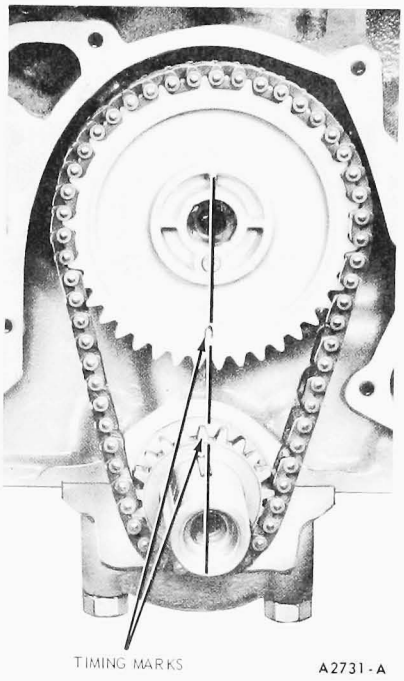

FIG. 22 Aligning Timing Marks

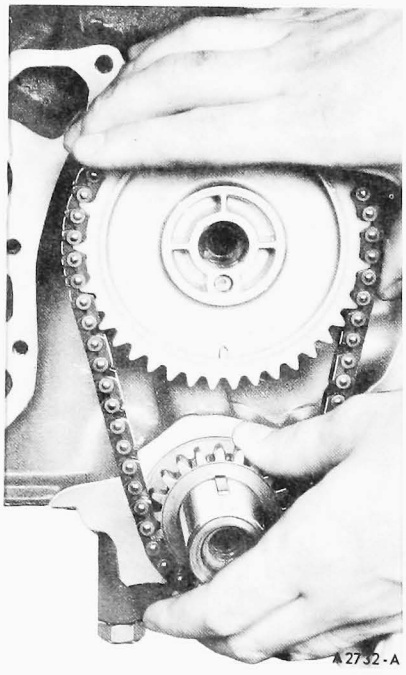

FIG. 23 Removing or Installing Timing Chain

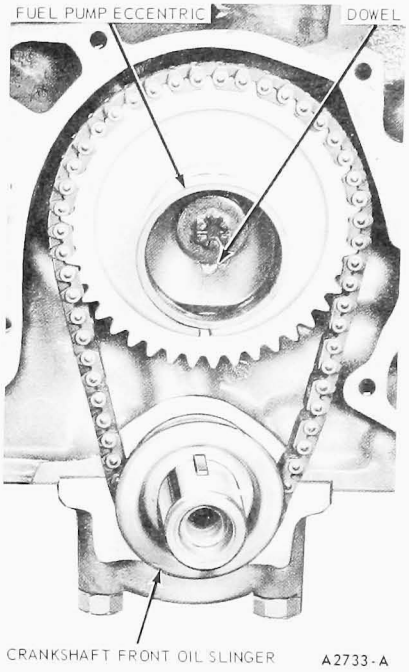

FIG. 24 Fuel Pump Eccentric and Front Oil Slinger—Installed

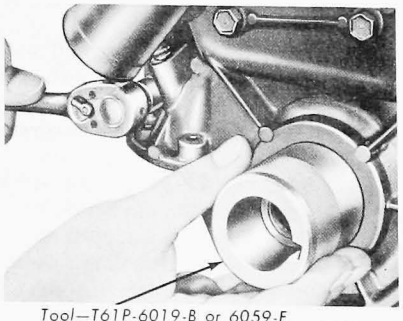

FIG. 25 Aligning Cylinder Front Cover

7. Install the cylinder front cover-to-seal alignment tool into proper position (Fig. 25).
8. It may be necessary to force the cover downward to slightly compress the pan gasket. This operation can be facilitated by using a suitable tool at the front cover attaching hole locations.
9. Coat the threads of the attaching screws with oil-resistant sealer and install the screws. While pushing in on the alignment tool, tighten the oil pan to cover attaching screws to specifications. Tighten the cover to block attaching screws to specifications. Remove the pilot.
10. Apply Lubriplate or equivalent to the oil seal rubbing surface of the vibration damper inner hub to prevent damage to the seal. Apply a white lead and oil mixture to the front of the crankshaft for damper installation.
11. Line up the crankshaft vibration damper keyway with the key on the crankshaft. Install the vibration damper on the crankshaft (Fig. 26). Install the capscrew and washer. Tighten the screw to specifications. Install the crankshaft pulley.
12. Lubricate the fuel pump lever with heavy engine oil and install the fuel pump using a new gasket. Connect the fuel pump outlet pipe. Connect the vacuum inlet and outlet lines (Bronco only).
13. Tighten the alternator pivot bolt and bolt attaching the alternator adjusting arm to the water pump.
14. Position the fan shroud over the water pump, if so equipped. Install the water pump pulley, spacer, fan and drive belts.
15. Connect the heater hose and water pump by-pass hose. Slide the by-pass hose clamp into position.
16. On Econoline vehicles only, install the radiator.
17. Connect the radiator hose(s). Install the bolts securing the fan shroud to the radiator, if so equipped.
18. Fill and bleed the cooling system.
19. Operate the engine at fast idle and check the coolant level and check for oil leaks. Check and adjust the ignition timing.
20. Install the air cleaner and intake duct assembly, including the crankcase ventilation hose.

FRONT OIL SEAL

Removal

1. Remove the cylinder front cover.
2. Drive out the old seal with a pin punch.

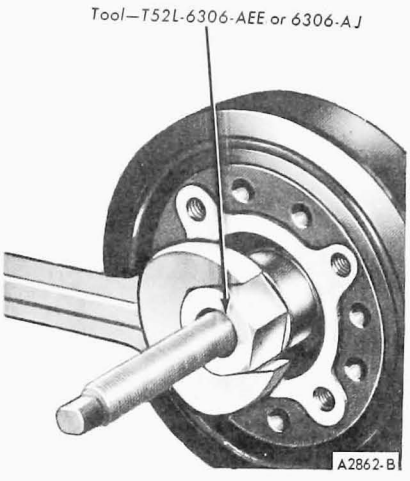

FIG. 26 Installing Crankshaft Vibration Damper

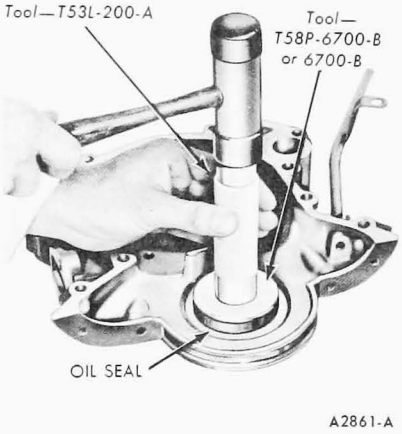

FIG. 27 Installing Crankshaft Front Oil Seal

Installation

1. Coat a new seal with grease, then install the seal in the cover (Fig. 27). Drive the seal in until it is fully seated in the recess.
2. Check the seal after installation to be sure the spring is properly positioned in the seal.
3. Install the cylinder front cover.

CAMSHAFT

The camshaft and related parts are shown in Fig. 28.

Removal

1. On Econoline vehicles, remove the grille.
2. Drain the cooling system. Disconnect the radiator upper and lower hoses. Disconnect the transmission oil cooler lines, if so equipped. Remove the radiator.
3. Remove the cylinder front cover and the timing chain, following the procedure under Cylinder Front Cover and Timing Chain Removal.
4. Disconnect the spark plug wires by hand only from the spark plugs and remove the wires from the ignition harness brackets on the valve rocker arm covers. Disconnect the coil high tension lead from the coil. Remove the distributor cap and spark plug wire assembly.
5. Disconnect the ignition coil wires from the coil.
6. Disconnect the distributor vacuum hoses from the carburetor and intake manifold. Remove the distributor hold-down bolt and clamp, then remove the distributor.
7. Disconnect the heater hose from the intake manifold.

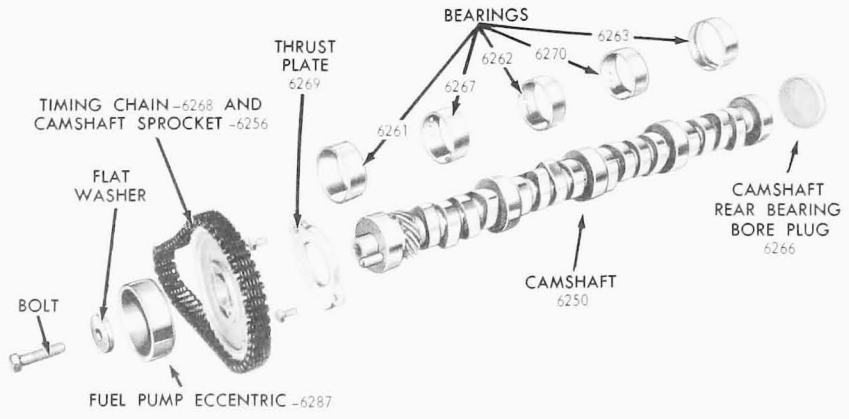

FIG. 28 Camshaft and Related Parts

8. Disconnect the accelerator rod and choke cable from the carburetor. Remove the accelerator retracting spring. Disconnect the automatic transmission kickdown rod at the carburetor and transmission vacuum line at the intake manifold (if so equipped).
9. Disconnect the water temperature sending unit wire from the sending unit and the engine ground strap at the engine.
10. Remove the crankcase ventilation regulator valve from the valve rocker arm cover. Remove the valve rocker arm covers. Loosen the valve rocker arm stud nuts and rotate the rocker arms to the side.
11. Remove the intake manifold and carburetor as an assembly. Remove the intake manifold gaskets and seals.
12. Remove the valve push rods in sequence so that they can be installed in their original positions.
13. Using Tool T70P-14151 shown in Fig. 19, remove the valve lifters and place them in a rack so that they can be installed in their original bores.
14. Remove the camshaft thrust plate. Carefully remove the camshaft by pulling toward the front of the engine. **Use caution to avoid damaging the camshaft bearings.**

Installation

1. Oil the camshaft journals and apply Lubriplate or equivalent to the lobes. Carefully slide the camshaft through the bearings. Lubricate the camshaft thrust plate with heavy engine oil SE and install the camshaft thrust plate with the groove toward the cylinder block.
2. Lubricate the lifters and lifter bore with heavy engine oil. Install the valve lifters in the bores from which they were removed, using Tool T70P-14151.
3. Lubricate the ends of the push rods with Lubriplate or equivalent and install the push rods in their original positions. Apply Lubriplate or equivalent to the valve stem tips. Lubricate the rocker arms and fulcrum seats with Lubriplate or equivalent and position the rocker arms over the push rods.
4. Install the intake manifold and related parts by following the steps under Intake Manifold Installation.
5. Connect the water temperature sending unit and the engine ground strap.
6. Connect the accelerator rod, choke cable and retracting spring. Connect the automatic transmission kickdown rod at the carburetor and transmission vacuum line at the intake manifold (if so equipped).
7. Connect the heater hose at the intake manifold. Position and connect the fuel line.
8. Replace the crankshaft front oil seal. Install the timing chain, cylinder front cover and related parts, following the steps under Cylinder Front Cover and Timing Chain Installation.
9. With No. 1 piston on TDC at the end of the compression stroke, position the distributor in the block with the rotor at the No. 1 firing position and the points just starting to open. Install the hold-down clamp.
10. Perform a valve clearance adjustment as outlined in this Part.
11. Clean the valve rocker arm covers and the cylinder head gasket surface. Place the new gaskets in the covers making sure that the tabs of the gasket engage the notches provided in the cover.
12. Position the covers on the cylinder heads. **Make sure the gasket seats evenly all around the cylinder head. Tighten the bolts to specifications in two steps. Two minutes later, tighten the bolts to the same specifications.**
13. Clean and install the crankcase ventilation system.
14. Connect the ignition coil wires.
15. Install the distributor cap. Position the spark plug wires in the harness brackets on the valve rocker arm covers and connect the wires to the plugs. Connect the high-tension lead at the coil.
16. Install the radiator and connect the hoses. Connect the oil cooler lines, if so equipped.
17. Fill and bleed the cooling system. Fill the crankcase with the proper grade and quantity of engine oil.
18. Start the engine, then check and adjust the ignition timing. Connect the distributor and intake manifold vacuum hoses.
19. Operate the engine at fast idle and check all hose connections and gaskets for leaks. Operate the engine until engine temperatures have stabilized, then adjust the engine idle speed and idle fuel mixture. Re-torque intake manifold bolts and nuts.
20. Install the air cleaner and intake duct assembly, including the crankcase ventilation hose.
21. On Econoline vehicles, install the grille.

FLYWHEEL

Removal

1. On a vehicle with a manual-shift transmission, remove the clutch pressure plate and disc following the procedures in Group 16.

On a vehicle with an automatic transmission, remove the transmission and converter housing following the procedure in Group 17.

2. To check flywheel face runout or to replace a flywheel ring gear for a manual-shift transmission, refer to Part 21-01.
3. Remove the flywheel attaching bolts and remove the flywheel.

Installation

1. Coat the threads of the flywheel attaching bolts with oil-resistant sealer. Position the flywheel on the crankshaft flange. Install and tighten the bolts in sequence across from each other to specifications.
2. On a vehicle with a manual-shift transmission, check the flywheel runout, following the procedure in Part 21-01. Install the clutch pressure plate, disc and the transmission, following the procedures in Group 16.

On a vehicle with an automatic transmission, check the flywheel runout, following the procedure in Part 21-01. Install the transmission and converter housing, following the procedure in Group 17.

CLUTCH PILOT BUSHING

Removal

1. Remove the clutch pressure plate and disc, following the procedures in Group 16.
2. Remove the pilot bushing as shown in Fig. 29.

Installation

1. Coat the pilot bushing bore in the crankshaft with a small quantity of wheel bearing lubricant. **Avoid using too much lubricant as it may be thrown onto the clutch disc when the clutch rotates.**
2. Install the pilot service bearing as shown in Fig. 30.
3. Install the clutch pressure plate, disc and the transmission, following the procedures in Group 16.

CAMSHAFT REAR BEARING BORE PLUG

Removal

1. Remove the transmission, clutch pressure plate and disc, following the procedures in Group 16.

On a vehicle with an automatic transmission, remove the transmission and converter housing following the procedure in Group 17.

2. Remove the flywheel attaching bolts and remove the flywheel. Remove the engine rear cover plate.
3. Replace the rear bearing bore plug as detailed in Part 21-01.

Installation

1. Coat the flywheel attaching bolts with oil-resistant sealer. Position the engine rear cover plate on the cylinder block dowels. Position the flywheel on the crankshaft flange. Install and tighten the attaching bolts in sequence, across from each other, to specifications.
2. On a vehicle with a manual-shift transmission, install the clutch pressure plate, disc and the transmission following the procedures in Group 16.
3. On a vehicle with an automatic transmission, install the transmission and converter housing, following the procedure in Group 17.

OIL PAN

F-100

Removal

1. Remove the oil dipstick.
2. Remove the bolts attaching the fan shroud to the radiator and position the shroud over the fan.
3. Remove the nuts and lock washers attaching the engine support insulators to the chassis bracket.
4. If equipped with an automatic transmission, disconnect the oil cooler line at the left side of the radiator.
5. Raise the engine and place wood blocks under the engine supports.
6. Drain the crankcase.
7. Remove the oil pan attaching bolts and lower the oil pan onto the crossmember.
8. Remove the two bolts attaching the oil pump pick-up tube to the oil pump. Lower the pick-up tube and screen into the oil pan.
9. Remove the oil pan from the vehicle.

Installation

1. Clean oil pan, inlet tube and gasket surfaces. Inspect the gasket sealing surface for damages and distortion due to overtightening of the bolts. Repair and straighten as required.
2. Position a new oil pan gasket and end seals to the cylinder block (Fig. 31).

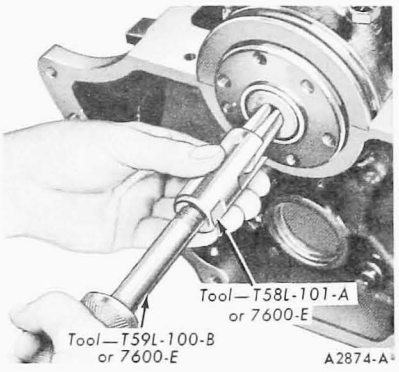

FIG. 29 Removing Clutch Pilot Bushing

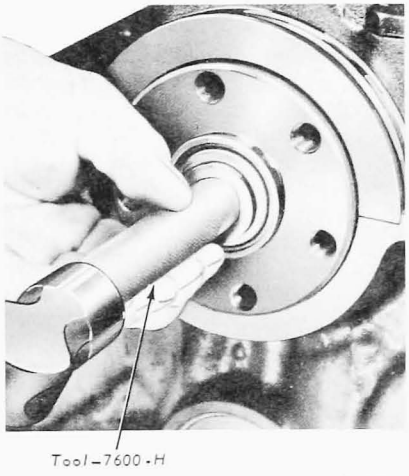

FIG. 30 Installing Clutch Pilot Bearing

3. Position the oil pick-up tube and screen to the oil pump, and install the lower attaching bolt and gasket loosely.
4. Place the oil pan on the crossmember. Install the upper pick-up tube bolt. Tighten the pick-up tube bolts to specifications.
5. Position the oil pan to the cylinder block and install the attaching bolts. Tighten to specifications.
6. Raise the engine and remove the wood blocks. Lower the engine and install the insulator-to-chassis bracket nuts and washers. Tighten the nuts to specifications.
7. If equipped with an automatic transmission, connect the oil cooler line at the radiator.
8. Install the fan shroud attaching bolts.
9. Fill the crankcase with the proper grade and quantity of engine oil. Install the oil dipstick. Start the engine and operate it until it reaches normal operating temperature, then check for leaks.

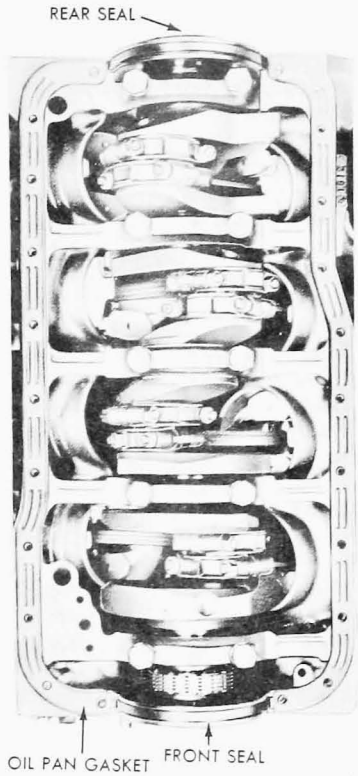

FIG. 31 Oil Pan Gaskets and Seals Installed

BRONCO

Removal

1. Remove the air cleaner, then remove the air cleaner duct. Remove the oil dipstick tube fastened to the exhaust manifold.
2. Drain crankcase and remove the oil pan attaching bolts. Remove the oil pan, seals and gasket.
3. Remove the oil pump pick-up tube and screen assembly.

Installation

1. Clean the oil pump pick-up tube and screen assembly. Inspect the gasket sealing surface for damages and distortion due to overtightening of the bolts. Repair and straighten as required.
2. Position new oil pan gasket and end seals to cylinder block (Fig. 31), then install the oil pump pick-up tube and screen assembly with the attaching bolts and nut.
3. Position the oil pan on the cylinder block, then install the attaching bolts.
4. Install the oil dipstick tube.
5. Install the air cleaner duct and air

cleaner. Start the engine and check for leaks.

ECONOLINE

Removal

1. Raise the vehicle on a hoist.
2. Remove the bolts fastening the oil dipstick tube to the exhaust manifold and oil pan. Position aside.
3. Drain the crankcase and remove the oil filter.
4. Disconnect steering rod end at idler arm.
5. Remove nuts and washers attaching engine front supports to engine support crossmember (Fig. 32).
6. Position a support jack under the damper and raise engine as required.
7. Remove nuts attaching engine support crossmember to side rails and frame. Remove engine support crossmember.
8. Position engine support tools (T68E-6038-A) to side rails and front engine supports. Install washers and nuts fastening support tools to side rails (Fig. 33). Lower support jack.
9. Remove oil pan bolts. Remove oil pan and inlet tube.

Installation

1. Clean oil pan, inlet tube and gasket surfaces. Inspect the gasket sealing surface for damages and distortion due to overtightening of the bolts. Repair and straighten as required.
2. Position a new oil pan gasket and end seals to cylinder block (Fig. 31), then install the oil pump inlet tube.
3. Position the oil pan to the cylinder block and install the attaching bolts and tighten to specifications.
4. Position a support jack under the damper and raise the engine as required.
5. Remove the engine support tools.
6. Position the engine support crossmember to side rails and frame. Install attaching bolts and nuts and tighten to specifications.
7. Lower engine and remove jack.
8. Install washers and nuts attaching engine supports to specifications.
9. Connect steering rod end at idler arm.
10. Connect the oil dipstick tube to the oil pan and exhaust manifold.
11. Install oil filter.
12. Lower vehicle and fill crankcase. Start the engine and check for leaks.

OIL PUMP

Removal

1. Remove the oil pan and related parts as outlined under Oil Pan Removal.
2. Remove the oil pump inlet tube and screen assembly.

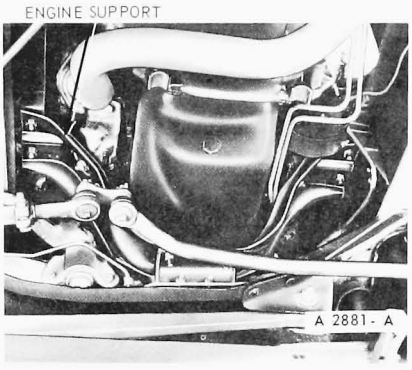

FIG. 32 Engine Support Crossmember—Econoline

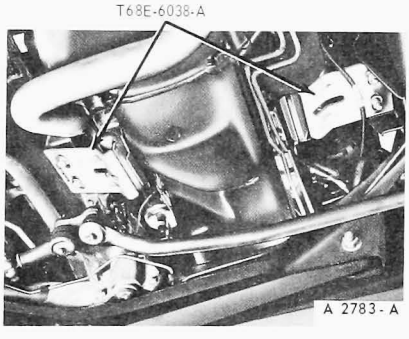

FIG. 33 Engine Support Tools Installed—Econoline

3. Remove the oil pump attaching bolts and remove the oil pump gasket and intermediate drive shaft.

Installation

1. Prime the oil pump by the inlet port with engine oil. Rotate the pump shaft to distribute the oil within the pump body.
2. Position the intermediate drive shaft into the distributor socket. With the shaft firmly seated in the distributor socket, the stop on the shaft should touch the roof of the crankcase. Remove the shaft and position the stop as necessary.
3. Position a new gasket on the pump housing. With the stop properly positioned, insert the intermediate drive shaft into the oil pump. Install the pump and shaft as an assembly. **Do not attempt to force the pump into position if it will not seat readily. The drive shaft hex may be misaligned with the distributor shaft. To align, rotate the intermediate drive shaft into a new position.** Tighten the oil pump attaching screws to specifications.
4. Clean and install the oil pump inlet tube and screen assembly.
5. Install the oil pan and related parts as outlined under Oil Pan Installation.

CRANKSHAFT REAR OIL SEAL

A split, lip-type crankshaft rear oil seal is used for replacement on 302 CID engines. **If replacement is necessary, this type of seal must be used. The complete seal can be replaced without removing the crankshaft.**

Removal

1. Remove the oil pan and the oil pump (if required).
2. Loosen all the main bearing cap bolts, thereby lowering the crankshaft slightly but not to exceed 1/32 inch.
3. Remove the rear main bearing cap, and remove the oil seal from the bearing cap and cylinder block. On the block half of the seal, use a seal removal tool or install a small metal screw in one end of the seal, and pull on the screw to remove the seal. **Exercise caution to prevent scratching or damaging the crankshaft seal surfaces.**
4. Remove the oil seal retaining pin from the bearing cap. **The pin is not used with the split, lip-type seal.**

Installation

1. Carefully clean the seal grooves in the cap and block with a brush and solvent.
2. Dip the split, lip-type seal halves in clean engine oil.
3. Carefully install the upper seal (cylinder block) into its groove with the undercut side of the seal toward the FRONT of the engine (Fig. 34), by rotating it on the seal journal of the crankshaft until approximately 3/8 inch protrudes below the parting surface.

Be sure no rubber has been shaved from the outside diameter of the seal by the bottom edge of the groove.

4. Tighten the remaining bearing cap bolts and torque to specifications.
5. Install the lower seal in the rear main bearing cap with the undercut side of the seal toward the FRONT of the engine (Fig. 34). Allow the seal to protrude approximately 3/8 inch above the parting surface to mate with the upper seal when the cap is installed.
6. Apply a thin coating of oil-resistant sealer to the rear main bearing cap at the rear of the top mating surface (Fig. 35). **Do not apply sealer to the area forward of the side seal groove.** Install the rear main bearing cap. Tighten the cap bolts to specifications.
7. Install the oil pump and oil pan. Fill

the crankcase with the proper amount and viscosity oil.
8. Operate the engine and check for oil leaks.

MAIN BEARING

The main bearing inserts are selective fit. Refer to the procedures under Fitting Main and Connecting Rod Bearings in Part 21-01.

Removal

1. Drain the crankcase. Remove the oil level dipstick. Remove the oil pan and related parts, following the procedure under Oil Pan Removal in this section.
2. Remove the oil pump inlet tube assembly and the oil pump.
3. **Replace one bearing at a time, leaving the other bearings securely fastened.** Remove the main bearing cap to which new bearings are to be installed.
4. Insert the upper bearing removal tool (tool 6331) in the oil hole in the crankshaft.
5. Rotate the crankshaft in the direction of engine rotation to force the bearing out of the block.
6. If the rear main bearing is being replaced, remove and discard the rear oil seal from the bearing cap.

Loosen all main bearing bolts, thereby lowering the crankshaft slightly but not to exceed 1/32 inch. Remove the block half of the rear oil seal. Use a seal removal tool or install a small metal screw in one end of the seal and pull on the screw to remove the seal. **Be careful not to burr the crankshaft seal rubbing surface.**

7. Clean the crankshaft journals. Inspect the journals and thrust faces (thrust bearing) for nicks, burrs or bearing pick-up that would cause premature bearing wear.

Installation

1. If the rear main bearing is being replaced, clean the rear oil seal groove in the block with a brush and solvent.

Carefully install the upper seal (split lip-type) into its groove with the undercut side of the seal toward the FRONT of the engine (Fig. 34) by rotating it on the seal journal of the crankshaft until approximately 3/8 inch protrudes below the parting surface.

Be sure no rubber has been shaved from the outside diameter of the seal by the bottom edge of the groove.

Tighten the bolts on main bearings 1, 2, 3 and 4, thereby raising the crankshaft to its original position. Tighten the bolts to specifications.

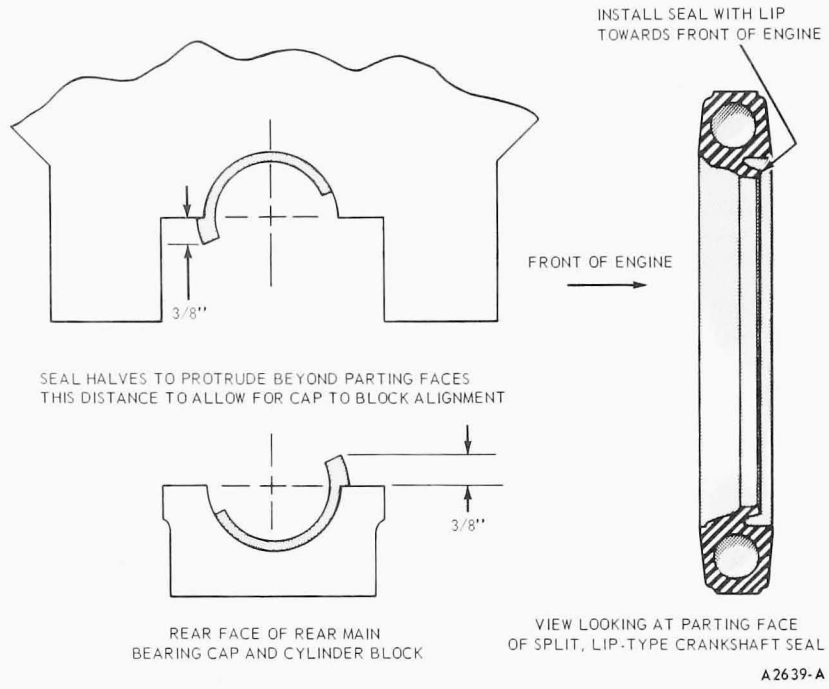

FIG. 34 Crankshaft Rear Oil Seal Installation

2. To install the upper main bearing, place the plain end of the bearing over the shaft on the locking tang side of the block and partially install the bearing so that tool 6331 can be inserted in the oil hole in the crankshaft. With tool 6331 positioned in the oil hole in the crankshaft, rotate the crankshaft in the opposite direction of engine rotation until the bearing seats itself. Remove the tool.
3. Install the bearing cap.
4. Select fit the bearing for proper clearance, following the procedures under Fitting Main and Connecting Rod Bearings in Part 21-01.
5. If the bearing is being replaced on journal number 1, 2 or 4, apply a coat of heavy engine oil SE to the journal and bearings and install the bearing cap. Tighten the cap bolts to specifications.
6. If the rear main bearing is to be replaced, remove the rear main oil seal retaining pin from the bearing cap seal groove. The pin is not used with the split, lip-type seal.

Clean the oil seal groove with a brush and solvent.

7. Install the lower seal in the rear main bearing cap with the undercut side of the seal toward the FRONT of the engine (Fig. 34). Allow the seal to protrude approximately 3/8 inch above the parting surface to mate with the upper seal when the cap is installed.

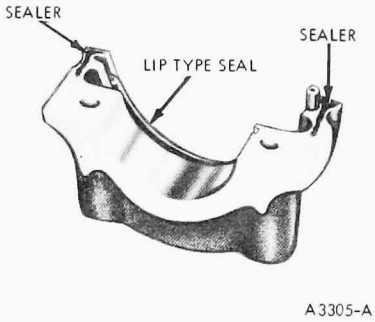

FIG. 35 Sealer on Rear Main Bearing Cap

8. Apply a thin coating of oil-resistant sealer to the rear main bearing cap at the rear of the top mating surface (Fig. 35). **Do not apply sealer to the area forward of the oil slinger groove.** Lubricate the journal with heavy engine oil SE and install the rear main bearing cap. Tighten the cap bolts to specifications.
9. If the thrust bearing cap (No. 3 main bearing) has been removed, install it as follows:

Lubricate the journal with heavy engine oil SE and install the thrust bearing cap with the bolts finger tight. Pry the crankshaft forward against the thrust surface of the upper half of the bearing. Hold the crankshaft cap to the rear. This will align the thrust surfaces

of both halves of the bearing. Retain the forward pressure on the crankshaft. Tighten the cap bolts to specifications (Fig. 36).

10. Clean the oil pump inlet tube screen. Prime the oil pump by filling the inlet opening with oil and rotating the pump shaft until oil emerges from the outlet opening. Install the oil pump and inlet tube assembly.
11. Position the oil pan gaskets on the oil pan. Position the oil pan front seal on the cylinder front cover. Position the oil pan rear seal on the rear main bearing cap. Install the oil pan and related parts, following the procedure under Oil Pan Installation in this section. Install the oil level dipstick.
12. Fill the crankcase. Start the engine and check for oil pressure. Operate the engine at fast idle and check for oil leaks.

CONNECTING ROD BEARINGS

The connecting rod bearings are selective fit. Refer to the procedures under Fitting Main and Connecting Rod Bearings in Part 21-01.

Removal

1. Drain the crankcase. Remove the oil level dipstick. Remove the oil pan and related parts, following the procedure under Oil Pan Removal.
2. Remove the oil pump inlet tube assembly and the oil pump.
3. Turn the crankshaft until the connecting rod to which new bearings are to be fitted is down. Remove the connecting rod cap. Remove the bearing inserts from the rod and cap.

Installation

1. Be sure the bearing inserts and the bearing bore in the connecting rod and cap are clean. Foreign material under the inserts will distort the bearing and cause a failure.
2. Clean the crankshaft journal.
3. Install the bearing inserts in the connecting rod and cap with the tangs fitting in the slots provided.
4. Pull the connecting rod assembly down firmly on the crankshaft journal.
5. Select fit the bearing, following procedures under Fitting Main and Connecting Rod Bearings in Part 21-01.
6. After the bearing has been fitted, clean and apply a coat of heavy engine oil SE to the journal and bearings. Install the connecting rod cap. Tighten the nuts to specifications.
7. Repeat the procedure for the remaining connecting rods that require new bearings.
8. Clean the oil pump inlet tube screen. Prime the oil pump by filling the inlet opening with oil and rotating the pump shaft until oil emerges from the outlet opening. Install the oil pump and inlet tube assembly.
9. Position the oil pan gaskets on the oil pan. Position the oil pan front seal on the cylinder front cover. Position the oil pan rear seal on the rear main bearing cap. Install the oil pan and related parts, following the procedure under Oil Pan Installation in this section. Install the oil level dipstick.
10. Fill the crankcase. Start the engine and check for oil pressure. Operate the engine at fast idle and check for oil leaks.

PISTONS AND CONNECTING RODS

Removal

1. Drain the cooling system and the crankcase. Remove the intake manifold, cylinder heads, oil pan and oil pump, following the procedures in this section.
2. Remove any ridges and/or deposits from the upper end of the cylinder bores as follows:

Turn the crankshaft until the piston to be removed is at the bottom of its travel, then place a cloth on the piston head to collect the cuttings. Remove the cylinder ridge with a ridge cutter. Follow the instructions furnished by the tool manufacturers. **Never cut into the ring travel area in excess of 1/32 inch when removing ridges.**

3. Make sure all connecting rod caps are marked so that they can be installed in their original positions.
4. Turn the crankshaft until the connecting rod being removed is down.
5. Remove the connecting rod nuts and cap.
6. Push the connecting rod and piston assembly out the top of the cylinder with the handle end of a hammer. **Avoid damage to the crankshaft journal or the cylinder wall when removing the piston and rod.**
7. Remove the bearing inserts from the connecting rod and cap.
8. Install the cap on the connecting rod from which it was removed.

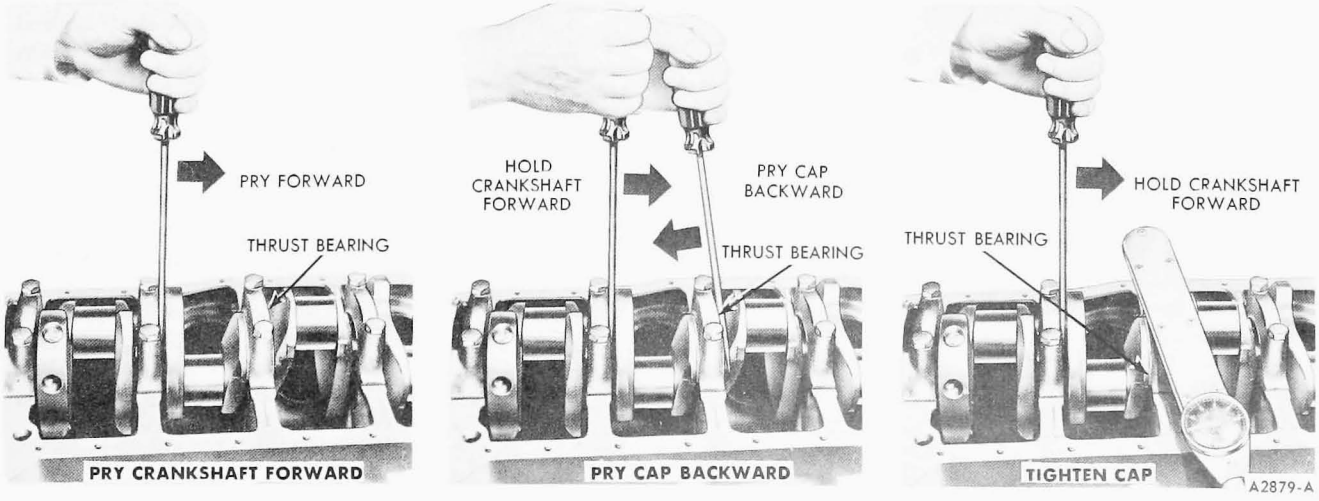

FIG. 36 Aligning Thrust Bearing

Installation

1. If new piston rings are to be installed, remove the cylinder wall glaze. Follow the instructions of the tool manufacturer.
2. Oil the piston rings, pistons and cylinder walls with heavy engine oil. **Be sure to install the pistons in the same cylinders from which they were removed or to which they were fitted. The connecting rod and bearing caps are numbered from 1 to 4 in the right bank and from 5 to 8 in the left bank, beginning at the front of the engine. The numbers on the connecting rod and bearing cap must be on the same side when installed in the cylinder bore. If a connecting rod is ever transferred from one block or cylinder to another, new bearings should be fitted and the connecting rod should be numbered to correspond with the new cylinder number.**

When installing the piston and connecting rod assembly, the largest chamfer at the bearing end of the rod should be positioned towards the crank pin thrust face of the crankshaft.

3. Make sure the ring gaps are properly spaced around the circumference of the piston (Fig. 37).
4. Install a piston ring compressor on the piston and push the piston in with a hammer handle until it is slightly below the top of the cylinder (Fig. 38). Be sure to guide the connecting rods to avoid damaging the crankshaft journals. **Install the piston with the indentation notch in the piston head toward the front of the engine.**
5. Check the clearance of each bearing, following the procedure under Fitting Main and Connecting Rod Bearings in Part 21-01.
6. After the bearings have been fitted, apply a light coat of engine oil to the journals and bearings.
7. Turn the crankshaft throw to the bottom of its stroke. Push the piston all the way down until the connecting rod bearing seats on the crankshaft journal.
8. Install the connecting rod cap. Tighten the nuts to specifications.
9. After the piston and connecting rod assemblies have been installed, check the side clearance between the connecting rods on each shaft journal (Fig. 39).

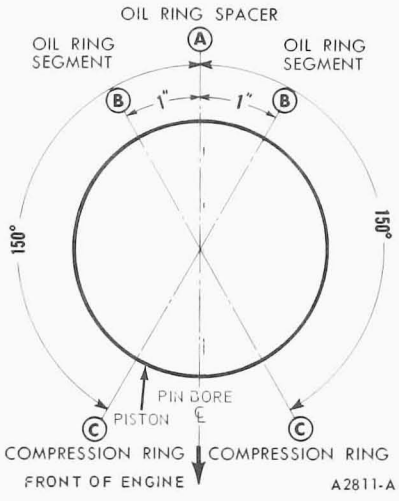

FIG. 37 Piston Ring Spacing

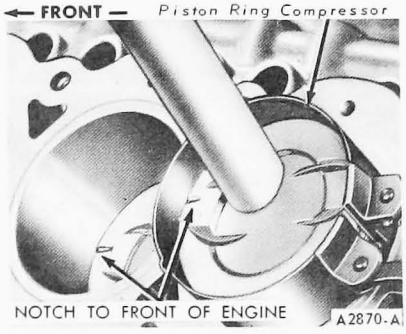

FIG. 38 Installing Piston

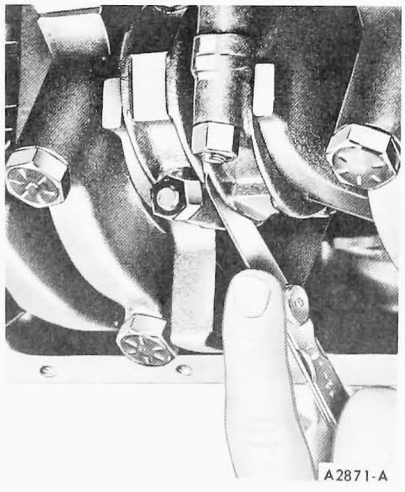

FIG. 39 Checking Connecting Rod Side Clearance

10. Disassemble, clean, and assemble the oil pump. Clean the oil pump inlet tube screen and the oil pan and block gasket surfaces.
11. Prime the oil pump by filling the inlet port with engine oil and rotating the pump shaft to distribute the oil within the housing. Install the oil pump and the oil pan, following the procedures under Oil Pan Installation in this section.
12. Install the cylinder heads, following the steps under Cylinder Head Installation.
13. Install the intake manifold, following the steps under Intake Manifold Installation.
14. Fill and bleed the cooling system. Fill the crankcase with the proper grade and quantity of engine oil.
15. Start the engine, then check and adjust the ignition timing. Connect the distributor vacuum hoses to the distributor.
16. Operate the engine at fast idle and check for oil and coolant leaks. Operate the engine until engine temperatures have stabilized, then adjust the engine idle speed and idle fuel mixture.
17. Install the air cleaner and intake duct assembly, including the crankcase ventilation hose.

CRANKSHAFT

The crankshaft and related parts are shown in Fig. 40.

Removal

1. Disconnect the spark plug wires at the spark plugs by hand only and remove the wires from the ignition harness brackets on the valve rocker arm covers. Disconnect the coil to distributor high-tension lead at the coil. Remove the distributor cap and spark plug wires as an assembly. Remove the spark plugs to allow easy rotation of the crankshaft.
2. Remove the fuel pump and oil filter. Slide the water pump by-pass hose clamp toward the water pump. Remove the alternator and mounting brackets.
3. Remove the crankshaft pulley from the crankshaft vibration damper. Remove the capscrew and washer from the end of the crankshaft. Install the puller on the crankshaft vibration damper (Figs. 20 and 21) and remove the damper.

4. Remove the cylinder front cover and water pump as an assembly.
5. Remove the crankshaft front oil slinger. Check the timing chain deflection, then remove the timing chain and sprockets by following steps under Cylinder Front Cover and Timing Chain Removal.
6. Invert the engine on the work stand. Remove the clutch pressure plate and disc (manual-shift transmission). Remove the flywheel and engine rear cover plate. Remove the oil pan and gasket. Remove the oil pump.
7. **Make sure all bearing caps (main and connecting rod) are marked so that they can be installed in their original locations.** Turn the crankshaft until the connecting rod from which the cap is being removed is down, and remove the bearing cap. Push the connecting rod and piston assembly up into the cylinder. Repeat this procedure until all the connecting rod bearing caps are removed.
8. Remove the main bearing caps.
9. Carefully lift the crankshaft out of the block so that the thrust bearing surfaces are not damaged. **Handle the crankshaft with care to avoid possible fracture or damage to the finished surfaces.**

To refinish journals, dress minor imperfections, etc., refer to Part 21-01.

Installation

1. Remove rear journal oil seal from the block and rear main bearing cap.
2. Remove the main bearing inserts from the block and bearing caps.
3. Remove the connecting rod bearing inserts from the connecting rods and caps.
4. If the crankshaft main bearing journals have been refinished to a definite undersize, install the correct undersize bearings. Be sure the bearing inserts and bearing bores are clean. Foreign material under the inserts will distort the bearing and cause a failure.
5. Place the upper main bearing inserts in position in bores with the tang fitting in the slot provided.
6. Install the lower main bearing inserts in the bearing caps.
7. Clean the rear journal oil seal groove and the mating surfaces of the block and rear main bearing cap. Remove the rear oil seal retainer pin from the rear main bearing cap seal groove. The pin is not used with the split, lip-type seal.
8. Dip the lip-type seal halves in clean engine oil. Install the seals in the bearing cap and block with the undercut side of the seal toward the FRONT of the engine as shown in Fig. 34.
9. Carefully lower the crankshaft into place. **Be careful not to damage the bearing surfaces.**
10. Check the clearance of each main bearing by following the procedure under Fitting Main and Connecting Rod Bearings in Part 21-01.
11. After the bearings have been fitted, apply a thin coating of oil-resistant sealer to the rear main bearing cap at the rear of the top mating surface (Fig. 35). **Do not apply sealer to the area forward of the oil slinger groove.**
12. Apply heavy engine oil SE to the journals and bearings.
13. Install all the bearing caps, except the thrust bearing cap (No. 3 bearing). **Be sure that the main bearing caps are installed in their original locations.** Tighten the bearing cap bolts to specifications.
14. Install the thrust bearing cap with the bolts finger-tight.
15. Pry the crankshaft forward against the thrust surface of the upper half of the bearing (Fig. 36).
16. Hold the crankshaft forward and pry the thrust bearing cap to the rear (Fig. 36). This will align the thrust surfaces of both halves of the bearing.
17. Retain the forward pressure on the crankshaft. Tighten the cap bolts to specification (Fig. 36).
18. Force the crankshaft toward the rear of the engine.
19. Check the crankshaft end play (Refer to Part 21-01).
20. Install new bearing inserts in the connecting rods and caps. Check the clearance of each bearing, following the procedure under Fitting Main and Connecting Rod Bearings in Part 21-01.
21. After the connecting rod bearings have been fitted, apply a light coat of engine oil SE to the journals and bearings.
22. Turn the crankshaft throw to the bottom of its stroke. Push the piston all the way down until the rod bearing seats on the crankshaft journal.
23. Install the connecting rod cap. Tighten the nuts to specifications.
24. After the piston and connecting rod assemblies have been installed, check the side clearance between the connecting rods on each connecting rod crankshaft journal (Fig. 39).
25. Install the timing chain and sprockets, cylinder front cover and crankshaft pulley and adapter, following steps under Cylinder Front Cover and Timing Chain Installation.
26. Coat the threads of the flywheel

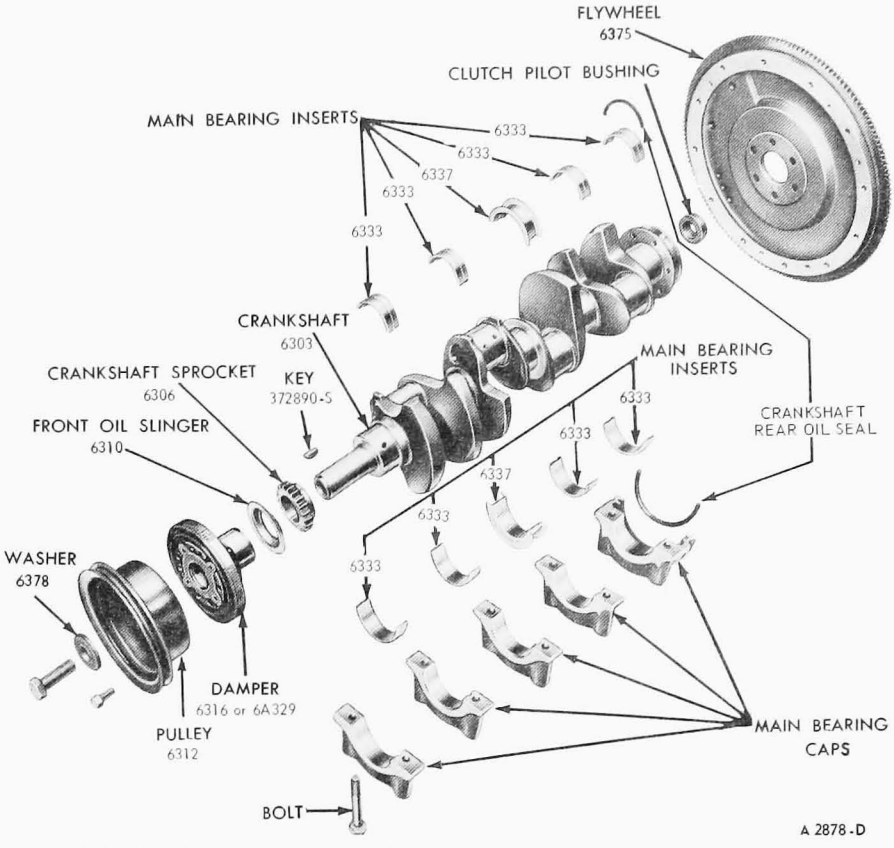

FIG. 40 Crankshaft and Related Parts

attaching bolts with oil-resistant sealer. Position the flywheel on the crankshaft flange. Install and tighten the bolts to specifications.

On a flywheel for manual-shift transmission, use Tool 6392-N to locate the clutch disc. Install the pressure plate. Tighten the attaching bolts.

27. Clean the oil pan, oil pump and oil pump screen. Prime the oil pump by filling the inlet port with engine oil and rotating the pump shaft to distribute oil within the housing. Install the oil pump and oil pan by following the procedures under Oil Pan and Oil Pump Installation.
28. Install the oil filter, fuel pump and connect the fuel lines. Install the alternator, shield and mounting bracket.
29. Install the spark plugs, distributor cap and spark plug wires. Connect the spark plug wires and high-tension lead.
30. Install the engine in the vehicle.

CAMSHAFT BEARINGS

Camshaft bearings are available pre-finished to size for standard and 0.015 inch undersize journal diameters. The bearings are not interchangeable from one bore to another.

Removal

1. Remove the camshaft, flywheel and crankshaft, following the appropriate procedures. Push the pistons to the top of the cylinders.
2. Remove the camshaft rear bearing bore plug as detailed in Part 21-01. Remove the camshaft bearings (Fig. 41).
3. Select the proper size expanding collet and back-up nut and assemble on the expanding mandrel. With the expanding collet collapsed, install the collet assembly in the camshaft bearing, and tighten the back-up nut on the expanding mandrel until the collet fits the camshaft bearing.
4. Assemble the puller screw and extension (if necessary) as shown and install on the expanding mandrel. Wrap a cloth around the threads of the puller screw to protect the front bearing or journal. Tighten the pulling nut against the thrust bearing and pulling plate to remove the camshaft bearing. Be sure to hold a wrench on the end of the puller screw to prevent it from turning.
5. Repeat the procedure for each bearing. To remove the front bearing, install the puller screw from the rear of the cylinder block.

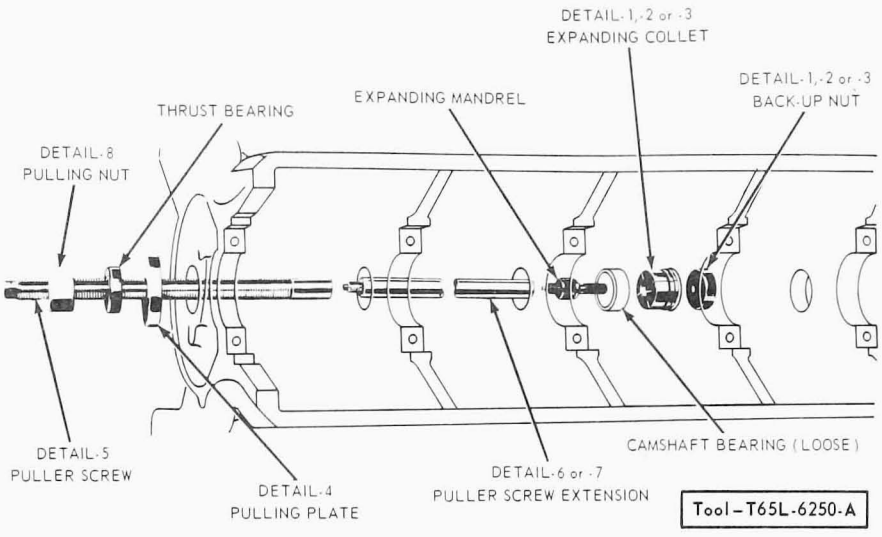

FIG. 41 Camshaft Bearing Replacement

Installation

1. Position the new bearings at the bearing bores with the oil holes aligned and press them in place with the tool shown in Fig. 41. Be sure to center the pulling plate and puller screw to avoid damage to the bearing. **Failure to use the correct expanding collet can cause severe bearing damage. Be sure the front bearing is installed the specified distance below the front face of the cylinder block (Fig. 42).**
2. Install a new rear bearing bore plug.
3. Install the camshaft, crankshaft, flywheel and related parts, following the appropriate procedures, except do not check connecting rod and main bearing clearances as a part of Camshaft Bearing Replacement. Install the engine in the vehicle.

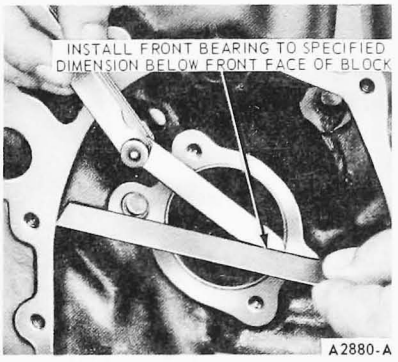

FIG. 42 Camshaft Front Bearing Replacement

OIL FILTER

The oil filter assembly is shown in Fig. 43.

Removal

1. Position a drip pan under the oil filter.
2. Unscrew the filter from the adpater fitting and clean the adapter fitting.

On Econolines equipped with power steering, be sure the wheels are fully to the right before removing the filter. Then unscrew the filter from the adapter fitting, turn it horizontal and let the excess oil drain off. Slide the oil filter towards the rear of the vehicle and remove as shown in Fig. 36. Some effort may be required to slide the oil filter between the engine crossmember and power steering hoses.

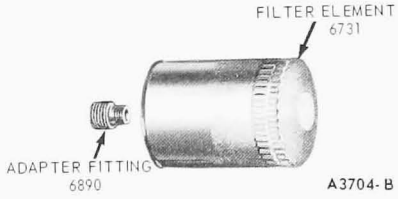

FIG. 43 Oil Filter Assembly

Installation

1. Coat the gasket on a new filter with oil. Place the new filter in position on the adapter fitting.

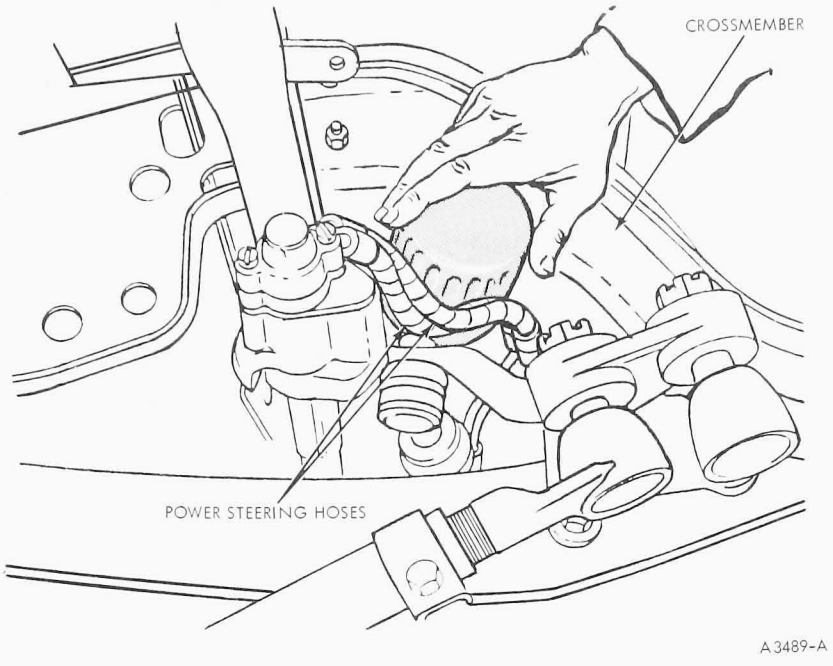

FIG. 44 Oil Filter Replacement—Econoline with Power Steering

On Econolines equipped with power steering, make sure that the wheels are turned fully to the right, then slide the oil filter between the crossmember and power steering hoses (Fig. 44) to position it on the adpater fitting.

2. Hand tighten the filter until the gasket makes contact and then advance it 1/2 turn.
3. Operate the engine at fast idle and check for oil leaks. If oil leaks are evident, perform the necessary repairs to correct the leakage. Remove the drip pan.
4. Check the oil level and fill the crankcase as necessary.

DISASSEMBLY AND ASSEMBLY

When installing nuts or bolts that must be tightened (Refer to torque specifications), oil the threads with light-weight engine oil. **Do not oil threads that require oil-resistant or water-resistant sealer.**

Refer to part 21-01 for the cleaning and inpsection procedures.

ENGINE ASSEMBLY

Disassembly

1. Install the engine on the work stand.
2. Remove the distributor cap, coil high-tension wire and spark plug wires as an assembly.
3. Remove the distributor vacuum hoses from the distributor. Remove the carburetor fuel inlet line. Remove the fuel pump outlet line and fuel filter. Remove the pump vacuum lines (Bronco only). Remove the fuel pump and discard the gasket. Remove the oil filter.
4. Slide the clamp on the water pump by-pass hose toward the water pump.
5. Remove the valve rocker arm covers and the crankcase ventilating system.
6. Remove the alternator mounting brackets. Remove the ignition coil. Remove the distributor hold-down bolt and remove the distributor.
7. Remove the intake manifold attaching bolts. Raise the manifold and carefully remove it from the engine. Discard the intake manifold gaskets and seals.
8. Loosen the valve rocker arm stud not so that the valve rocker arms can be rotated to the side. Remove the valve push rods in sequence and put them in a rack or holder so that they can be installed in their original position.
9. Remove the valve lifters and place them in a rack so that they can be installed in their original bores (Fig. 19).

The internal parts of each hydraulic valve lifter assembly are matched sets. Do not intermix the parts. Keep the assemblies intact until they are to be cleaned.

10. Remove the exhaust manifolds and the spark plug.
11. Install the cylinder head holding fixtures (Fig. 15). Remove the cylinder head bolts and lift the cylinder heads off the block. Discard the cylinder head gaskets.
12. Remove the crankshaft pulley from the crankshaft vibration damper. Remove the capscrew and washer from the end of the crankshaft. Install the pulley on the crankshaft vibration damper (Figs. 20 and 21) and remove the vibration damper.
13. Remove the oil pan-to-cylinder front cover attaching bolts. Remove the cylinder front cover attaching bolts. Remove the cylinder front cover and water pump as an assembly. Discard the gasket and remove the crankshaft front oil slinger.
14. Check the timing chain deflection and remove the timing chain and sprockets by following steps under Cylinder Front Cover and Timing Chain Removal. Remove the crankshaft sprocket key.
15. Remove any ridge and/or carbon deposits from the upper end of the cylinder bores. Move the piston to the bottom of its travel and place a cloth on the piston head to collect the cuttings. Remove the cylinder ridge with a ridge cutter. Follow the instructions furnished by the tool manufacturer. **Never cut into the ring travel area in excess of 1/32 inch when removing ridges.** After the ridge has been removed, remove the cutter from the cylinder bore.
16. On a flywheel for a manual-shift transmission, remove the clutch pressure plate and disc.
17. Remove the flywheel and rear cover

plate. Remove the clutch pilot bushing (Fig. 29).

18. Invert the engine. Remove the oil pan and discard the gaskets and seals.
19. Remove the oil pump and inlet tube as an assembly. Remove the intermediate drive shaft. Discard the oil pump gasket.
20. **Make sure all connecting rods and caps are marked so that they can be installed in their original locations. Turn the crankshaft until the connecting rod being removed is down. Remove the rod cap.**
21. Push the connecting rod and piston assembly out the top of the cylinder with the handle end of a hammer. **Avoid damage to the connecting rod journal or the cylinder wall when removing the piston and rod.**
22. Remove the bearing inserts from the connecting rods and caps. Install the rod caps on the connecting rods from which they were removed.
23. Remove the main bearing caps.
24. Carefully lift the crankshaft out of the cylinder block so that the thrust bearing surfaces are not damaged. **Handle the crankshaft with care to avoid possible fracture or damage to the finished surfaces.**
25. Remove the rear journal oil seal from the block and rear bearing cap.
26. Remove the main bearing inserts from the block and bearing caps. Install the main bearing caps in their original positions.
27. Remove the camshaft thrust plate. Carefully remove the camshaft by pulling it toward the front of the engine. Use caution to avoid damaging the journals and lobes.
28. Remove the camshaft rear bearing bore plug. Remove the camshaft bearings (Fig. 41).

Assembly

If the cylinder block is to be replaced, transfer the cylinder head dowels and cylinder block drain plugs to the new cylinder block and start the assembly procedures with step number 5.

1. If the original cylinder block is used, remove the glaze from the cylinder bores by following the instructions in Part 21-01.
2. Invert the engine on the work stand.
3. Position the new camshaft bearings at the bearing bores with the oil holes aligned and press them in place with the tool shown in Fig. 41. **Be sure the camshaft front bearing is installed the specified distance below the front face of the cylinder block (Fig. 42).**
4. Clean out the camshaft rear bearing bore plug recess thoroughly. Install the new bore plug as detailed in Part 21-01.
5. Oil the camshaft journals with heavy engine oil SE and apply Lubriplate or equivalent to all lobes, and then carefully slide it through the bearings. Install the camshaft thrust plate, with groove towards engine block, and then check camshaft end play as shown in Part 21-01.
6. Clean the rear journal oil seal groove and the mating surfaces of the block and rear main bearing cap. Remove the rear oil seal retainer pin from the rear main bearing cap seal groove. The pin is not used with the split, lip-type seal.
7. Dip the seal halves in clean engine oil SE. Install the seals in the bearing cap and block with the undercut side of the seal toward the FRONT of the engine as shown in Fig. 34.
8. If the crankshaft main bearing journals have been refinished to a definite undersize, install the correct undersize bearings. Be sure the bearing inserts and bearing bores are clean. Foreign material under the inserts will distort the bearing and cause a failure.

Place the upper main bearing inserts in position in the bore with the tang fitting in the slot provided.

9. Install the lower main bearing inserts in the bearing caps.
10. Carefully lower the crankshaft into place. **Be careful not to damage the bearing surfaces.**
11. Check the clearance of each main bearing, following the procedure under Fitting Main and Connecting Rod Bearings in Part 21-01.
12. After bearings have been fitted, apply a coat of heavy engine oil SE to the journals and bearings.
13. Apply a thin coating of oil-resistant sealer to the rear main bearing cap at the rear of the top mating surface (Fig. 35). **Do not apply sealer to the area forward of the oil slinger grooves.** Install the rear main bearing cap and the remainder of the caps, except the thrust bearing cap (No. 3 bearing). **Be sure that the main bearing caps are installed in the original positions.** Tighten the bearing cap bolts to specifications.
14. Install the thrust bearing cap and check crankshaft end play by following steps under Crankshaft Installation.
15. Turn the engine on the work stand so that the front end is up.
16. Install the pistons and connecting rods by following steps under Piston and Connecting Rod Installation.
17. Position the sprockets and timing chain on the camshaft and crankshaft (Fig. 23). Be sure the timing marks on the sprockets are positioned as shown in Fig. 22.
18. Lubricate the timing chain and sprockets with heavy engine oil SE.
19. Install the fuel pump eccentric, washer and camshaft sprocket capscrew. Tighten the sprocket capscrew to specifications. Apply heavy engine oil SE to the fuel pump eccentric. Install the crankshaft front oil slinger (Fig. 24).
20. Clean the cylinder front cover and the cylinder block gasket surfaces. Install a new crankshaft front oil seal (Fig. 27).
21. Coat the gasket surface of the block and cover and the cover bolt threads with oil-resistant sealer. Position a new gasket on the block.
22. Install the alignment pilot tool on the cylinder front cover so that the key in the pilot aligns with the key in the crankshaft. Position the cover (and water pump) and pilot over the end of the crankshaft and against the block (Fig. 25).
23. Install the cylinder front cover screw finger tight. While pushing in on the pilot, tighten the cover bolts to specifications. Remove the pilot.
24. Lubricate the crankshaft with a white lead and oil mixture and apply Lubriplate or equivalent to the oil seal rubbing surface of the vibration damper inner hub to prevent damage to the oil seal.
25. Line up the crankshaft vibration damper keyway with the key on the crankshaft, and then install the vibration damper on the crankshaft (Fig. 26). Install the damper capscrew and washer, then tighten the screw to specifications. Install the crankshaft pulley (power steering only).
26. Invert the engine on the work stand. Position the intermediate drive shaft into the distributor socket. With the shaft firmly seated in the distributor socket, the stop on the shaft should touch the roof of the crankcase. Remove the shaft and position the stop as necessary.
27. With the stop properly positioned, insert the intermediate drive shaft into the oil pump.
28. Prime the oil pump by filling the inlet port with engine oil. Rotate the pump shaft to distribute the oil within the pump body.
29. Position a new gasket on the pump housing and install the pump and shaft as an assembly. **Do not attempt to force the pump into position if it will not seat readily. The drive shaft hex may be misaligned with the distributor shaft. To align, rotate**

the intermediate shaft into a new position. Tighten the oil pump attaching bolt to specifications.

30. Clean the gasket surfaces of the block and oil pan. Coat the block surface and the oil pan gasket surface with sealer. Position new gaskets on the block and position a new seal on the cylinder front cover and rear main bearing cap. Make sure the tabs on the seal are over the oil pan gasket. Install the attaching bolts and tighten them from the center outwards to specifications (one screw secures the fuel line bracket).
31. Lubricate the fuel pump lever with heavy engine oil SE. Using a new gasket, install the fuel pump. Tighten the bolts alternately and evenly to specifications.
32. Turn the engine on the work stand so that the top of the engine is up.
33. Clean the cylinder head and block gasket surfaces. On the 302 V-8 engines, a specially treated composition gasket is used. **Do not apply sealer to a composition gasket. Install the head gaskets over the cylinder head dowels.**
34. Place the cylinder heads on the engine, then remove the holding fixtures. Oil the head bolt threads with heavy engine oil SE, then install the bolts.
35. The cylinder head bolt tightening procedure is performed in three progressive steps. Tighten the bolts in sequence (Fig. 16) to specifications.
36. Coat the cylinder head mating surfaces of the exhaust manifold with a light film of graphite grease.
37. Position the exhaust manifolds on the cylinder heads and install the attaching bolts and flat washers. Tighten the bolts to specifications, working from the center to the ends.
38. Install the spark plugs.
39. Use the hydraulic valve lifter leakdown tester (Part 21-01) to fill the lifters with test fluid. Lubricate the lifters and bores with heavy engine oil and install each lifter in the bore from which it was removed.
40. Lubricate the ends of the push rods with Lubriplate or equivalent and install the push rods in their original positions. Apply Lubriplate or equivalent over the valve stem tips. Lubricate the rocker arms and fulcrum seats with Lubriplate or equivalent and install the rocker arms over the push rods. Perform a valve clearance adjustment.
41. Clean the mating surfaces of the intake manifold, cylinder heads and cylinder block.
42. Coat the intake manifold and cylinder block seal surfaces with quick-setting adhesive.
43. Position new seals on the cylinder block and new gaskets on the cylinder heads with the gaskets interlocked with the seal tabs. Apply nonhardening sealer at the four junction points of the seals and gaskets. Be sure the holes in the gaskets are aligned with the holes in the cylinder heads.
44. Carefully lower the intake manifold on the cylinder block and cylinder heads. **After the intake manifold is in place, run a finger around the seal area to make sure the seals are in place. If the seals are not in place, remove the intake manifold and position the seals.**
45. Be sure the holes in the manifold gaskets and manifold are in alignment. Install the intake manifold attaching nuts and bolts. Tighten the intake manifold nuts and bolts in two steps (Fig. 13).

Tighten in sequence to specifications. **After completing the remaining assembly steps, operate the engine until it reaches normal operating temperature, then retighten the manifold nuts and bolts in sequence to specifications.**

46. Install the water pump by-pass hose on the coolant outlet housing. Slide the clamp into position and tighten the clamp.
47. Rotate the crankshaft until the No. 1 piston is on TDC after the compression stroke, then position the distributor in the block with the rotor at the No. 1 firing position and the points just start to open. Install the hold-down clamp.
48. Clean the valve rocker arm covers and the cylinder head gasket surface. Place the new gaskets in the covers making sure that the tabs of the gasket engage the notches provided in the cover.
49. Position the covers on the cylinder heads. Make sure the gasket seats evenly all around the head. Install the bolts. The cover is tightened in two steps. Tighten the bolts to specifications. Two minutes later, tighten the bolts to the same specifications.
50. Install the ignition coil. Position and install the alternator, shield and mounting brackets.
51. Install the crankcase ventilation system.
52. Install the distributor cap. Position the spark plug wires in the brackets on the valve rocker arm covers. Connect the spark plug wires and the coil wire.
53. Connect the carburetor fuel inlet line and fuel pump inlet line.
54. Install the oil filter adapter fitting. Clean the oil filter gasket surface. Coat the gasket on the filter with oil. Place the filter in position on the adapter fitting. Hand tighten the filter until the gasket contacts the adapter face; then, advance it 1/2 turn.
55. Install the clutch pilot service bearing (Fig. 30). Coat the threads of the flywheel attaching bolts with oil-resistant sealer. Position the rear cover plate on the block and the flywheel on the crankshaft flange. Install and tighten the bolts to specifications.

On a flywheel for a manual-shift transmission, use tool T58P-7563-A to locate the clutch disc. Install the pressure plate.

56. Install the engine in the vehicle. Fill and bleed the cooling system. Fill the crankcase with the proper grade and quantity of engine oil.
57. Operate the engine and check for oil and coolant leaks. Check and adjust the ignition timing. Connect the distributor vacuum hoses at the distributor. Retighten intake manifold bolts to specifications.
58. Adjust the engine idle speed, fuel mixture and anti-stall dashpot (if applicable). Adjust the transmission throttle linkage.

CYLINDER HEADS

Disassembly

1. Remove the exhaust manifolds and the spark plugs.
2. Clean the carbon out of the cylinder head combustion chambers before removing the valves.
3. Compress the valve spring (Fig. 45). Remove the spring retainer locks and release the spring.
4. Remove the spring retainer, sleeve, spring, stem seal and valve. Discard the valve stem seals. Identify all valve parts.
5. Clean, inspect and repair the cylinder head as required, or transfer all usable parts to a new cylinder head.

Assembly

1. Install each valve (Fig. 46) in the port from which it was removed or to which it was fitted. Install a new stem seal on the valve.

2. Install the valve spring over the valve, and then install the spring retainer and sleeve. Compress the spring (Fig. 45) and install the retainer locks (Fig. 46).
3. Measure the assembled height of the valve spring from the surface of the cylinder head spring pad to the underside of the spring retainer with dividers (Fig. 47). Check the dividers against a scale. If the assembled height is greater than specifications, install the necessary 0.030 inch thick spacer(s) between the cylinder head spring pad and the valve spring to bring the assembled height to the recommended height.

Do not install the spacers unless necessary. Use of spacers in excess of recommendations will result in overstressing the valve springs and overloading the camshaft lobes which could lead to spring breakage and worn camshaft lobes.

4. Install the exhaust manifolds and the spark plugs.

VALVE LIFTER

The internal parts of each hydraulic valve lifter assembly are matched sets. Do not intermix the parts. Keep the assemblies intact until they are to be cleaned.

The disassembly and assembly procedures for Types I and II valve lifters are different. Valve lifters should always be tested after assembly; refer to the test procedures covered in Part 21-01.

TYPE I

Disassembly

Disassemble and assemble each lifter separately. Keep the lifter assemblies in proper sequence so that they can be installed in their original bores.

1. Grasp the lock ring with needle nose pliers to release it from the groove. It may be necessary to depress the plunger to fully release the lock ring.
2. Remove the push rod cup, metering valve (disc), plunger and spring.
3. Remove the plunger assembly, the check valve and the check valve retainer and plunger spring. Carefully remove the plunger spring, the check valve retainer and, the check valve disc from the plunger.

Assembly

Type I hydraulic lifter assembly is shown in Fig. 48.

1. Place the plunger upside down on a clean work bench.
2. Place the check valve (disc or ball check) in position over the oil hole on the bottom of the plunger. Set the check valve spring on top of the check valve (disc or ball check).
3. Position the check valve retainer over the check valve and spring and push the retainer down into place on the plunger.
4. Place the plunger spring, and then the plunger (open end up) into the lifter body.
5. Position the metering valve (disc) in the plunger, and then place the push rod cup in the plunger.
6. Depress the plunger, and position the closed end of the lock ring in the groove of the lifter body. With the plunger still depressed, position the open ends of the lock ring in the groove. Release the plunger, and then depress it again to fully seat the lock ring.
7. Use the hydraulic valve lifter leakdown tester (Part 21-01) to fill the lifters with test fluid.

TYPE II

Disassembly

Each valve lifter is a matched assembly. If parts of one lifter are intermixed with those of another, improper valve operation may result. Disassemble and assemble each lifter separately. Keep the lifter assemblies in proper sequence so they can be installed in their original bores.

1. Grasp the lock ring with needle nose pliers to release it from the groove. It may be necessary to depress the plunger to fully release lock ring.
2. Remove the push rod cup.
3. Remove the plunger assembly, the check valve and the check valve retainer and plunger spring.

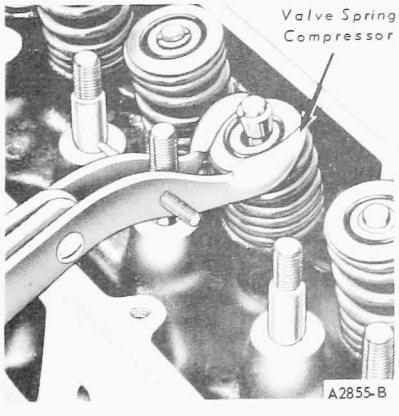

FIG. 45 Compressing Valve Spring On Bench

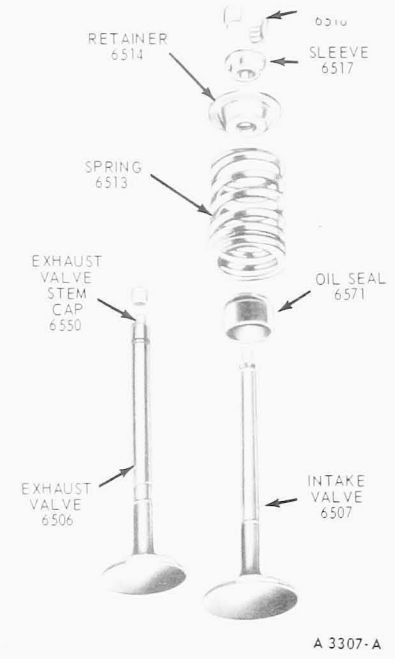

FIG. 46 Valve Assembly

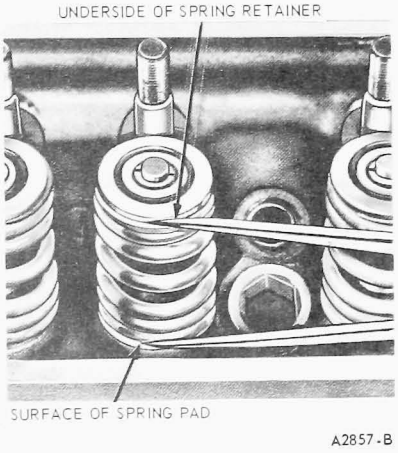

FIG. 47 Checking Valve Spring Assembled Height

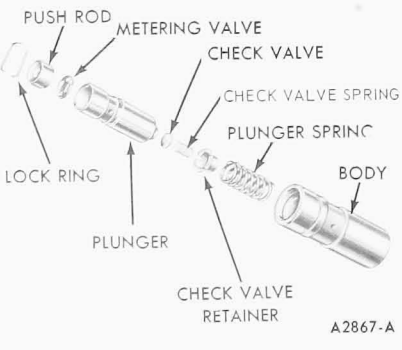

FIG.48 Type I Hydraulic Valve Lifter Assembly

Carefully remove the plunger spring, the check valve retainer and the check valve ball and spring from the plunger.

Assembly

Type II hydraulic lifter assembly is shown in Fig. 49.

1. Place the plunger on a clean work surface (table or bench) in an inverted position and center the check valve ball and spring on it. Carefully slide the check valve retainer over the ball and spring and down until it bottoms. **Use every precaution not to distort it in any way.** Place the plunger spring over the metering valve.
2. Leaving the assembly in the inverted position, slide the lifter body down over the spring until it slightly compresses the spring.
3. Position the combined assembly right side up on the work surface (table or bench).
4. Install the push rod cup. Depress the cup and install the lock ring.
5. Use the hydraulic valve lifter leakdown tester (Part 21-01) to fill the lifters with test fluid.

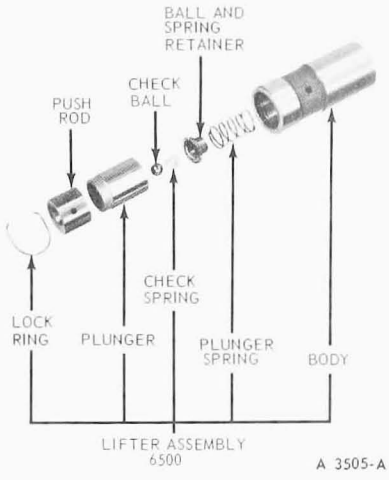

FIG. 49 Type II Hydraulic Valve Lifter Assembly

OIL PUMP

Disassembly

1. Remove the oil inlet tube from the oil pump and remove the gasket.
2. Remove the cover attaching bolts, then remove the cover. Remove the inner rotor and shaft assembly, then remove the outer race.
3. Drill a small hole and insert a self-threading sheet metal screw of the proper diameter into the oil pressure relief valve chamber cap and pull the cap out of the chamber. Remove the spring and plunger.

Assembly

The oil pump assembly is shown in Fig. 50.

1. Clean, inspect and oil all parts thoroughly.
2. Install the oil pressure relief valve plunger, spring and a new cap.
3. Install the outer race and the inner rotor and shaft assembly. **Be sure the dimple (identification mark) on the outer race is facing outward and on the same side as the identification mark on the rotor. The inner rotor and shaft and the outer race are serviced as an assembly. One part should not be replaced without replacing the other.** Install the cover and tighten the cover attaching bolts to specifications.
4. Position a new gasket and the oil inlet tube on the oil pump and install the attaching bolts.

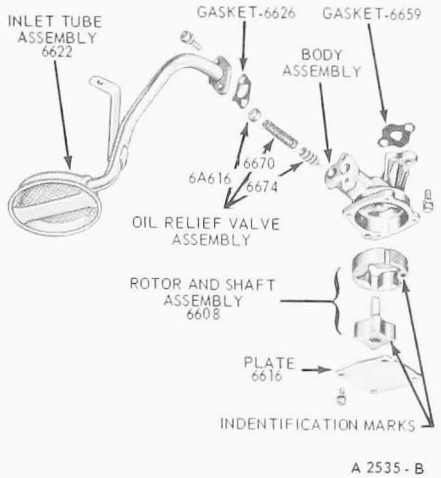

FIG. 50 Oil Pump—Disassembled

PISTONS AND CONNECTING RODS

Disassembly

1. Remove the bearing inserts from the connecting rod and cap.
2. Mark the pistons to assure assembly with the same rod and installation in the same cylinders from which they were removed.
3. Using an Arbor press and the tool shown in Fig. 51, press the piston pin from the piston and connecting rod. Remove the piston rings.

Assembly

The piston, connecting rod and related parts are shown in Fig. 52. Check the fit of a new piston in the cylinder bore before assembling the piston and piston pin to the connecting rod.

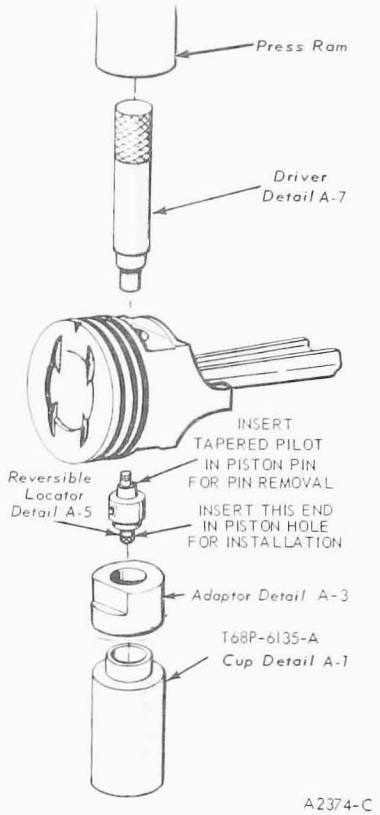

FIG. 51 Removing or Installing Piston Pin

The piston pin bore of a connecting rod and the diameter of the piston pin must be within specifications.

1. Apply a light coat of engine oil SE to all parts. **Assemble the piston to the connecting rod with the indentation in the piston positioned as shown in Fig. 53.**

On replacement connecting rods, install the large-chamfered side of the connecting rod bearing bore towards the crankshaft cheek; facing towards front of engine on the right bank rods, and facing towards rear of engine on left bank rods.

2. Start the piston pin in the piston and connecting rod (this may require a very light tap with a mallet). Using an Arbor Press, press the piston pin through the piston and connecting rod until the pin is centered in the piston (Fig. 51).
3. Check the end gap of all piston rings (Part 21-01). It must be within specifications. Follow the instructions contained on the piston ring package and install the piston rings.
4. Check the ring side clearance of the compression rings with a feeler gauge inserted between the ring and its lower land (Part 21-01). The gauge should slide freely around the

entire ring circumference without binding. Any wear that occurs will form a step at the inner portion of the lower land. **If the lower lands have high steps, the piston should be replaced.**

5. Be sure the bearing inserts and the bearing bore in the connecting rod and cap are clean. Foreign material under the inserts will distort the bearing and cause a failure. Install the bearing inserts in the connecting rod and cap with the tangs fitting in the slots provided.

CYLINDER ASSEMBLY

Disassembly

Follow steps 1 thru 9, 11 thru 13, and 16 thru 19 under Engine Disassembly. Remove the four cylinder head dowels from the cylinder block. Remove the cylinder block drain plugs, and remove the cylinder assembly from the work stand.

Assembly

Clean the gasket and seal surfaces of all parts and assemblies.

Install the replacement cylinder block assembly on a work stand. Install the cylinder block drain plugs and cylinder head dowels. Transfer all parts removed from the old cylinder assembly to the new cylinder assembly, following the procedures in steps 20 through 35 and 38 through 55 under Engine Assembly. Check all assembly clearances and correct as necessary.

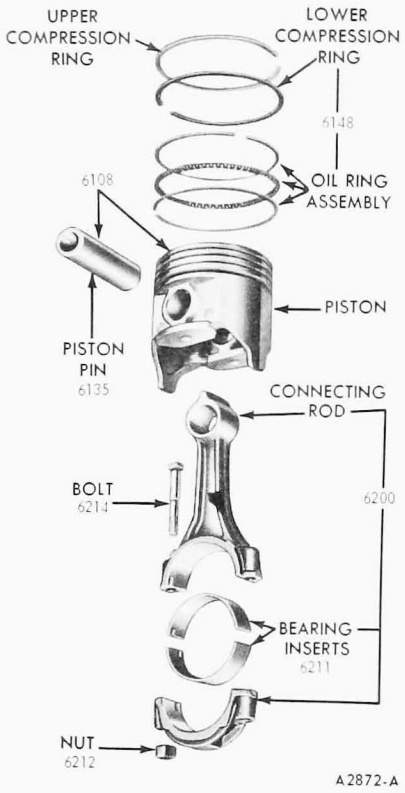

FIG. 52 Piston, Connecting Rod and Related Parts

CYLINDER BLOCK

Before replacing a cylinder block, determine if it is repairable, and make the necessary repairs following the procedures in Part 21-01.

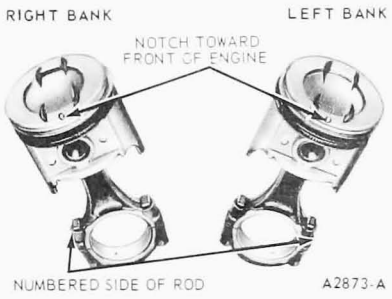

FIG. 53 Correct Piston and Rod Positions

Disassembly

Follow steps 1 through 9, 11 through 14, 16 through 24, 27 and 28 under Engine Disassembly. Remove the four cylinder head dowels and the cylinder block drain plugs from the cylinder block. Remove the cylinder block from the work stand.

Assembly

Install the replacement cylinder block on the work stand. Install the cylinder block drain plugs and cylinder head dowels. Transfer the parts removed from the old cylinder block to the new cylinder block by following steps 5 thru 36, 39 thru 58 under Engine Assembly. Check all assembly clearances and correct as necessary.

DESCRIPTION

ENGINES

MEDIUM AND HEAVY DUTY

The 330 MD V-8, 330 HD V-8, 361 HD V-8 and 391 HD V-8 engines (Fig. 1) have the same basic design. Refer to Part 21-01 for engine identification and application information.

The engines are available with either a standard mount fan or a high-mount fan for the B-, F-, LN-and LT-Series vehicles (Fig. 1). On C-Series vehicles, the fan is mounted on the crankshaft damper. The 330, 361 and 391 HD V-8 engines are equipped with exhaust valve seat inserts. The 361 and 391 CID engines are equipped with intake valve seat inserts.

LIGHT DUTY

The 360 and the 390 V-8 engines are of the same basic design. A typical engine is shown in Fig. 2.

EXHAUST EMISSION CONTROL SYSTEM

The Imco exhaust emission control system improves engine combustion to reduce contaminants normally emitted through the exhaust system. This is achieved by using a specially-calibrated carburetor and distributor. The Exhaust Gas Recirculation (EGR) System is covered in Volume VI of this Manual.

CRANKCASE VENTILATION SYSTEM

On a positive closed-type crankcase ventilation system (Fig. 3), the complete system is sealed and connected to the air cleaner by a hose. Thus, the crankcase receives air from the air cleaner. If the system becomes restricted, a back-flow condition may occur, thereby venting the crankcase gases into the air cleaner silencing chamber.

The amount of regulator valve opening or restriction is governed by intake manifold vacuum pressure.

During idle, the high intake manifold vacuum overcomes the spring pressure and moves the valve to the Low-Speed Operation position (Fig. 4). With the valve in this low flow position, the ventilating air passes between the valve (jiggle pin) and the outlet port. In this position there is minimum ventilation, but it never completely seals off the air flow.

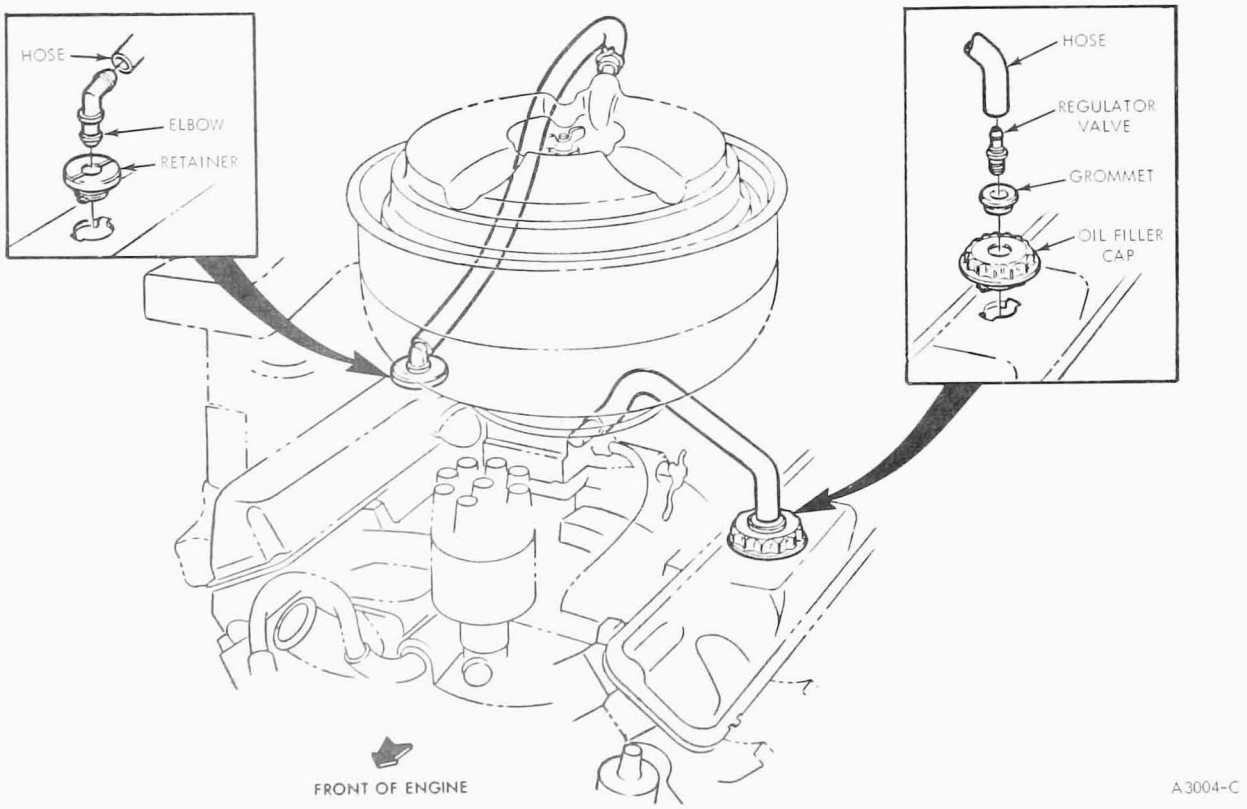

FIG. 3 Typical Crankcase Ventilation System

ADJUSTMENTS

VALVE CLEARANCE

The valve arrangement is E-I-E-I-I-E-I-E from front to rear on both cylinder banks.

A 0.060 inch longer and a 0.060 shorter than standard push rod is available for service to provide means of compensating for dimensional changes in the valve mechanism. Refer to the Master Parts List for the pertinent Part Number.

Valve stem to valve rocker arm clearance should be to the specified clearance with the hydraulic lifter completely collapsed. Repeated valve reconditioning operations (valve and/or valve seat refacing) will decrease the clearance to the point that if not compensated for, the hydraulic valve lifter will cease to function.

To determine whether a longer push rod is necessary, make the following check:

1. Install an auxiliary starter switch. Crank the engine with the ignition switch OFF.
2. **Position the crankshaft as outlined in steps 3 and 4.** Position a hydraulic lifter compressor tool on the rocker arm and slowly apply pressure to bleed down the hydraulic lifter until the plunger is completely bottomed (Fig. 5). Hold the lifter in the fully collapsed position and insert a low-limit (See Specifications) clearance gauge between the valve stem and the rocker arm of the valve being checked. If the gauge enters, the old push rod may be used. If a high-limit gauge enters, the operating range of the lifter is excessive which indicates severe wear has occurred at the push rod ends, rocker arm, or valve stem. In this case, it will be necessary to determine the area of discrepancy and the worn part(s) should be replaced. If all the valve train components except the push rod are within limits, install a 0.060-inch longer push rod.
3. Rotate the crankshaft until No. 1 piston is on TDC at the end of the compression stroke and check the following valves:
   No. 1 Intake-No. 1 Exhaust
   No. 3 Intake-No. 4 Exhaust
   No. 7 Intake-No. 5 Exhaust
   No. 8 Intake-No. 8 Exhaust
4. After these valves have been checked, rotate the crankshaft 360 degrees (one revolution) to position No. 6 piston on TDC and check the following valves:
   No. 2 Intake-No. 2 Exhaust
   No. 4 Intake-No. 3 Exhaust
   No. 5 Intake-No. 6 Exhaust
   No. 6 Intake-No. 7 Exhaust

To replace a push rod, it will be necessary to remove the valve rocker arm shaft assembly.

Upon replacement of a valve push rod and/or valve rocker arm shaft assembly, the engine should not be cranked or rotated until the hydraulic lifters have had an opportunity to leak down to their normal operating position. The leakdown rate can be accelerated by using the tool shown in Fig. 5 on the valve rocker arm and applying pressure in a direction to collapse the lifter.

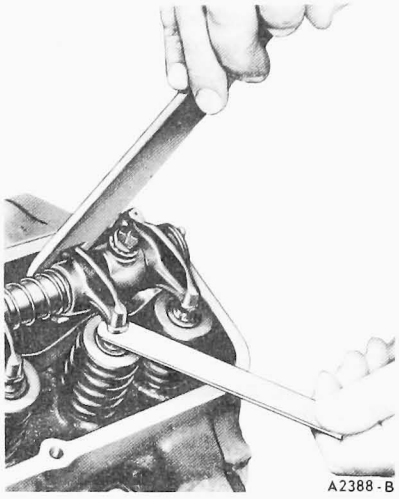

FIG. 5 Checking Valve Clearance

REMOVAL AND INSTALLATION

When installing nuts or bolts that must be torqued (refer to the pertinent section for torque specifications), oil the threads with light weight engine oil. **Do not oil threads that require oil-resistant or water resistant sealer.** Always Lubricate all bearing surfaces and/or mating surfaces with SE engine oil at assembly.

ENGINE ASSEMBLY

B, F AND LT-SERIES

Removal

1. Drain the cooling system and the engine crankcase.
2. Disconnect the ground cable from the battery.
3. Remove the hood from the vehicle.
4. Disconnect the radiator upper hose from the engine, and the lower hose from the water pump.
5. Remove the fan attaching bolts and remove the fan.
6. Remove the air cleaner and vent hose from the carburetor.
7. Remove the radiator attaching bolts. If the vehicle is equipped with an automatic transmission, disconnect the oil cooler lines from the radiator lower tank. Carefully lift the radiator and hoses from the engine compartment.
8. Disconnect the wires from the alternator and place them to one side.
9. Drain the air system and disconnect the air line at the compressor.
10. Disconnect the cable from the starter motor. Remove the three starter motor attaching bolts. Remove the starter.
11. Disconnect the muffler inlet pipe from each exhaust manifold.
12. Disconnect the body-to-engine ground strap from the engine.
13. Disconnect the accelerator linkage at the dash.
14. Disconnect the choke cable (manual choke) and the throttle cable from the carburetor.
15. Disconnect the tachometer cable from the distributor.
16. Disconnect the heater hose from the engine.
17. Disconnect the treadle valve air line.
18. Disconnect the fuel pump flex line from the fuel line. Cap the tank line.
19. Disconnect the wiring harness from the engine.
20. Remove the ignition coil and the

mounting bracket from the engine.
21. Disconnect the drive shaft center bearing retainer from the cross member to permit raising or lowering the transmission.
22. Position a jack under the transmission to support it.
23. Remove the cover from the lower end of the clutch housing.
24. Remove the attaching bolts from the lower half of the clutch housing.
25. Secure engine lifting brackets (Tool T58P-6000-A) to the cylinder heads.
26. Remove the nuts that secure the engine front support to the upper insulator.
27. Remove the remaining clutch housing attaching bolts.
28. Secure the lifting sling (Tool T53L-300-A) to the lifting brackets and raise the engine high enough to remove the bolts that attach the engine front support bracket to the upper insulator.
29. Carefully lift the engine away from the transmission and out of the chassis.
30. Install the engine on a workstand.

Installation

1. Install the engine lifting brackets (Tool T58P-6000-A) on the engine and attach the hoist and lifting sling (Tool T53L-300-A). Remove the engine from the workstand.
2. Lower the engine into the chassis. Align the clutch hub splines with those on the transmission input shaft. Push the engine into place against the clutch housing and install the attaching bolts.
3. Remove the jack from under the transmission.
4. Lower the engine to align the engine front support bracket with the upper insulator, then install the attaching bolts and nuts. Remove the engine lifting sling and brackets from the engine. Torque the nuts to specifications.
5. Secure the drive shaft center bearing support to the frame crossmember.
6. Install the cover on the lower end of the clutch housing.
7. Position a new gasket on each exhaust manifold flange. Secure the muffler inlet pipes to the exhaust manifolds.
8. Position the starter motor to the clutch housing and secure it with the attaching bolts and lock washers. Connect the cable to the starter.
9. Connect the alternator wires to their respective terminals.
10. Secure the coil and the bracket to the left cylinder head.
11. Connect the fuel pump flex line to the fuel line.
12. Connect the accelerator linkage to the linkage at the dash panel.
13. Connect the treadle valve air line.
14. Connect the choke cable (manual choke) and the throttle cable to the carburetor and adjust both.
15. Connect the tachometer cable to the distributor.
16. Connect the engine wiring harness to the respective connectors.
17. Connect the body-to-engine-ground strap to the rear of the engine.
18. Connect the heater hoses to the outlets on the engine.
19. Connect the main air line to the compressor.
20. Position the fan in the radiator shroud.
21. Carefully position the radiator (with hose) into place. Install the radiator attaching bolts.
22. Position the fan on the water pump pulley (or high mount), and secure it in place with the attaching bolts.
23. Connect the radiator upper hose to the outlet on the engine and the lower hose to the water pump.
24. Fill and bleed the cooling system.
25. Install the hood.
26. Fill the crankcase to the proper level with the recommended oil.
27. Connect the battery cables.
28. Adjust the clutch as required.
29. Start the engine and check for oil and water leaks.
30. Install the air cleaner and vent hose.

C-AND CT-SERIES

Removal

1. Release the cab lock and tilt the cab forward. Drain the cooling system and the crankcase.
2. Disconnect the ground cable from the battery.
3. Remove the clamps holding the throttle, choke and tachometer cables. Remove the clamps securing the heater hoses to the radiator.
4. Remove the air cleaner. Disconnect the accelerator rod, throttle cable and choke cable (manual choke) from the carburetor and position out of the way. Disconnect the tachometer cable from the distributor.

   On a vehicle with an air compressor, remove the compressor belt.
5. Remove the fan from the crankshaft damper and lay it inside the fan shroud.

   On a vehicle with an automatic transmission, disconnect the transmission oil cooler inlet and outlet lines at the radiator lower tank.
6. Disconnect the radiator upper hose at the water outlet housing and the lower hose at the radiator.
7. Disconnect and remove the vent line between the radiator and the supply tank and the hose between the water outlet housing and the supply tank.
8. Remove the radiator attaching bolts and insulators from the top brackets and the nuts and insulators from the bottom support rods. Remove the radiator, shroud and fan as an assembly.
9. Disconnect the heater hoses at the water pump and intake manifold and position out of the way.
10. Disconnect the tachometer cable from the distributor and position out of the way. Remove the ignition coil.
11. Remove the radiator supply tank from the cab rear support.
12. Disconnect the flexible fuel line from the tank line. Cap the tank line.
13. Disconnect the windshield wiper and vacuum brake hoses from the intake manifold.

    On a vehicle with an air compressor, release the air pressure and disconnect the main air line from the compressor.
14. Disconnect the wires from the alternator and the engine wires at the junction block.
15. Remove the clutch return spring. Remove the hydraulic clutch slave cylinder attaching bolts.
16. Remove the left and right muffler inlet pipe attaching bolts from the exhaust manifolds and disengage the inlet pipes.
17. Disconnect the starter cable from the starter. Remove the starter attaching bolts and remove the starter (ground strap is held by one starter bolt).

    On a vehicle with power steering, remove the power steering pump and reservoir and position it out of the way.
18. Position a floor jack under the transmission.
19. Remove the flywheel housing inspection cover attaching bolts and remove the cover. Remove the flywheel housing-to-engine attaching bolts.
20. Remove the nuts and bolts from the engine front support and upper insulator.
21. Attach the lifting brackets (Tool T58P-6000-A) to the engine.
22. Using a hoist and lifting sling (Tool T53L-300-A), remove the engine from the chassis.
23. Install the engine on a workstand.

Installation

1. Attach lifting brackets (Tool T58P-6000-A) and lifting sling (Tool T53L-300-A) to the engine. Remove the engine from the workstand.
2. Position the engine in the chassis, using a floor crane. Engage the

clutch hub splines with the transmission input shaft and slide the engine back against the transmission.

3. Install the flywheel housing-to-engine attaching bolts and tighten to specifications. Install the flywheel housing inspection cover. Remove the jack from under the transmission.
4. Lower the engine to align the front support bracket with the upper insulator, and install the bolts and nuts. Torque to specifications. Remove the engine lifting sling and lifting brackets.

On a vehicle with power steering, install the power steering unit.

5. Install the starter, positioning the ground strap under one of the attaching bolts. Tighten the attaching bolts to specifications. Attach the starter cable to the starter.
6. Install the left and right muffler inlet pipes to the exhaust manifolds, using new gaskets. Tighten the bolts to specifications.
7. Install the hydraulic clutch slave cylinder to the flywheel housing. Attach the clutch return spring.
8. Connect the alternator wires to their respective terminals. Connect the engine wires to the junction block.

On a vehicle with an air compressor, connect the main air line.

9. Connect the brake hose to the intake manifold vacuum connections.
10. Remove the cap from the fuel line and connect it to the flexible line on the fuel pump.
11. Install the radiator supply tank to the cab rear support.
12. Install the ignition coil to the left bank cylinder head. Connect the tachometer cable to the distributor.
13. Connect the heater hoses to the water pump and to the intake manifold.
14. Install the radiator, shroud and fan (loose, inside shroud) in the chassis. Secure the radiator with insulators and nuts to the bottom support rods and insulators and belts to the top brackets.
15. Connect the radiator-to-supply tank vent tube, the radiator lower hose to the radiator and the radiator upper hose to the water outlet housing.
16. Install and connect the water outlet housing-to-supply tank hose. On a vehicle with an automatic transmission, connect the transmission oil cooler inlet and outlet lines to the radiator.
17. Install the fan on the crankshaft damper and torque the bolts to specifications.

On a vehicle with an air compressor, install the air compressor belt and adjust belt tension to specifications.

18. Connect the accelerator rod, throttle cable and choke cables (manual choke) to the carburetor. Install the air cleaner.
19. Attach the heater hoses, throttle cable, choke cable and tachometer cable.
20. Connect the ground cable to the battery.
21. Fill the crankcase and cooling systems with the specified lubricant and coolant.
22. Operate the engine at fast idle and check for oil and water leaks.
23. Lower the cab and lock it in position.

LN-AND LNT-SERIES

Removal

1. Position a suitable support in front of the truck to hold the hood and fender assembly when it is fully forward.
2. Raise the hood and fender assembly. Disconnect and remove the battery.
3. Drain the cooling system and the crankcase.
4. Disconnect the check cable assemblies and allow the hood to swing forward out of the way, resting on the previously positioned support.
5. Remove the radiator-to-cowl support rod.
6. On a vehicle with power steering, disconnect the power steering pressure line from the pump reservoir and return line from the pump housing. Drain the oil into a suitable container. Loosen and remove the power steering drive belt.
7. Disconnect the radiator upper hose from the thermostat housing and the lower hose from the water pump.
8. Refer to the disconnect points for this radiator shown in Group 27 and remove the radiator.
9. Remove the bolts attaching the fan blade to the water pump hub (or high-mount fan hub).
10. On a vehicle with an air compressor, release the air pressure from the system. Disconnect the main air line from the air compressor. Disconnect the main air line from the treadle valve.
11. Remove the air cleaner.
12. Disconnect the heater hoses from the engine.
13. Disconnect the flexible fuel line (fuel pump to fuel tank) at the fuel tank line and install a cap on the tank line.
14. Disconnect the choke control cable (manual choke) and the throttle control cable at the carburetor. Disconnect the accelerator linkage.
15. Disconnect the tachometer cable from the distributor, remove the tachometer cable retaining brackets, and position the cable out of the way. Remove the ignition coil.
16. Disconnect the vacuum line from the engine intake manifold.
17. Disconnect the engine wiring harness from the engine.
18. Disconnect the wires from the alternator.
19. Remove the flywheel housing cover. Remove the flywheel housing lower attaching bolts.
20. Disconnect the starter cable from the starter. Remove the starter attaching bolts and remove the starter motor, dust cover and engine ground strap.
21. Remove the left and right muffler inlet pipe attaching nuts from the manifold and disengage the inlet pipes.
22. Remove the drive shaft center bearing retainer to permit raising and lowering of the drive shaft and transmission. Position a jack under the transmission.
23. Remove the flywheel housing to engine upper bolts.
24. Remove the bolt(s) attaching the engine front mounting plate to the engine front mount.
25. Attach the engine lifting brackets (Tool T58P-6000-A) to the cylinder heads. Attach a hoist and lifting sling (Tool T53L-300-A) to the engine lifting brackets.
26. Raise the engine just enough to remove the front support bracket-to-upper insulator bolts and nuts.
27. Remove the engine from the engine compartment, and install it on a workstand.

Installation

1. Install the engine lifting brackets (Tool T58P-6000-A) to the cylinder heads. Attach hoist and lifting sling (T53L-300-A) to the lifting brackets and remove the engine from the work stand.
2. Position the engine to align the front support bracket with the upper insulator. Install the bolts and nuts, then torque to specifications.
3. Install the flywheel housing-to-engine bolts and torque to specifications.
4. Lower the engine and remove the transmission jack. Remove the engine lifting brackets.

5. Install the bolt(s) attaching the engine mounting plate to the engine front mount and tighten the bolts to specifications.
6. Install the drive shaft center bearing retainer.
7. Install the flywheel housing cover attaching bolts.
8. Place new gaskets on the end of the muffler inlet pipes and position in the right and left exhaust manifolds. Install the attaching bolts and tighten to specifications.
9. Position the starter in the starter opening. Install the engine ground strap and starter attaching bolts, then tighten the bolts to specifications. Connect the starter cable to the starter.
10. Connect the wires to the alternator.
11. Position the engine wiring harness to the engine and connect the four connectors.
12. Connect the vacuum line to the intake manifold.
13. Position the tachometer cable on the engine, attach the two attaching clamps, and connect the tachometer cable to the distributor. Install the ignition coil.
14. Connect the choke cable (manual choke) and the throttle cable to the carburetor. Connect the accelerator linkage.
15. Remove the cap from the fuel tank line. Connect the flexible line to the fuel tank line.
16. Connect the heater hoses to the engine.
17. Install the carburetor air cleaner.
18. On a vehicle with air brakes, connect the main air line to the compressor and the air line to the treadle valve.
19. Install the fan blade on the hub. Tighten the bolts to specifications.
20. Install the radiator.
21. Connect the radiator lower hose to the water pump and the radiator upper hose to the thermostat housing.

On a vehicle with power steering, install and tighten the drive belt. Connect the power steering pressure line to the pump housing and the return line to the pump reservoir.

22. Position the radiator support rod to the cowl and radiator and install attaching nuts. Tighten the nuts to specifications.
23. Fill the crankcase with the recommended oil. Fill the cooling system.
24. Raise the hood and connect the check cables.
25. Install and connect the battery.
26. Start the engine and check for leaks.
27. Close the hood and fender assembly.

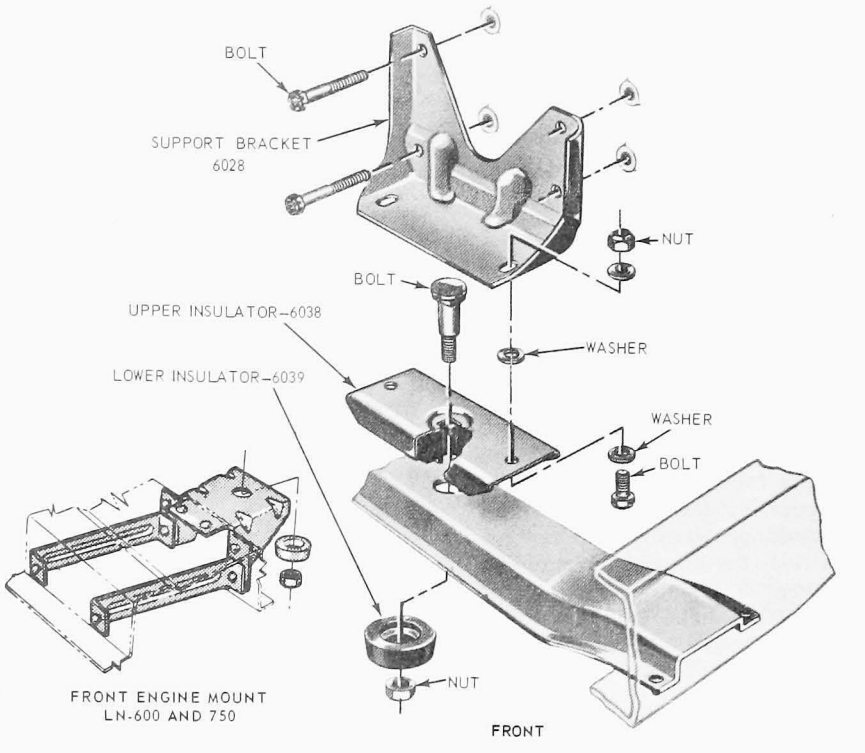

FIG. 6 Engine Front Supports — C-600-800, CT-800-F, B-500-750, LN-600-750

ENGINE FRONT SUPPORTS

When installing engine supports, be sure that the engine is correctly aligned on the supports and that the attaching bolts and/or nuts are torqued to specifications.

The various engine front supports are shown in Figs. 6 through 9.

SINGLE FRONT TYPE

Removal

1. Remove the insulator-to-frame attaching nut(s) and the lower insulator(s).
2. Remove the upper insulator-to-support bracket nuts, washers (and bolts, if so equipped).
3. Loosen the engine rear support insulator nuts approximately 1/4 turn.
4. Raise the engine about 1 inch with a jack and a block of wood placed under the oil pan; then, remove the insulator. On models shown in Fig. 7, remove the bolt from the upper insulator.
5. To remove the support bracket from the engine, remove the attaching bolts.

Installation

1. If the support bracket was removed from the engine, position it on the cylinder front cover, and install the attaching bolts. Torque the bolts to specifications.
2. On models shown in Fig. 7, install the upper insulator center bolt in the insulator. Position the upper insulator assembly on the support bracket, and install the bolts, washers and nuts, fingertight. On models shown in Fig. 7, install the nuts and washers fingertight.
3. Lower the engine and install the lower insulator(s) and attaching nut(s). Torque all the nuts to specification.
4. Torque the engine rear support nuts to specifications.

DOUBLE FRONT TYPE

Removal

1. Remove the insulator-to-support bracket nut and lock washer (Figs. 8 and 9). **If only one insulator is being removed, loosen the other insulator.**
2. Check for possible interference between the fan and fan shroud or engine accessories when the engine is raised for insulator removal. Using a jack and wood block placed under the oil pan, raise the engine just enough to allow clearance for removal of the insulator(s).

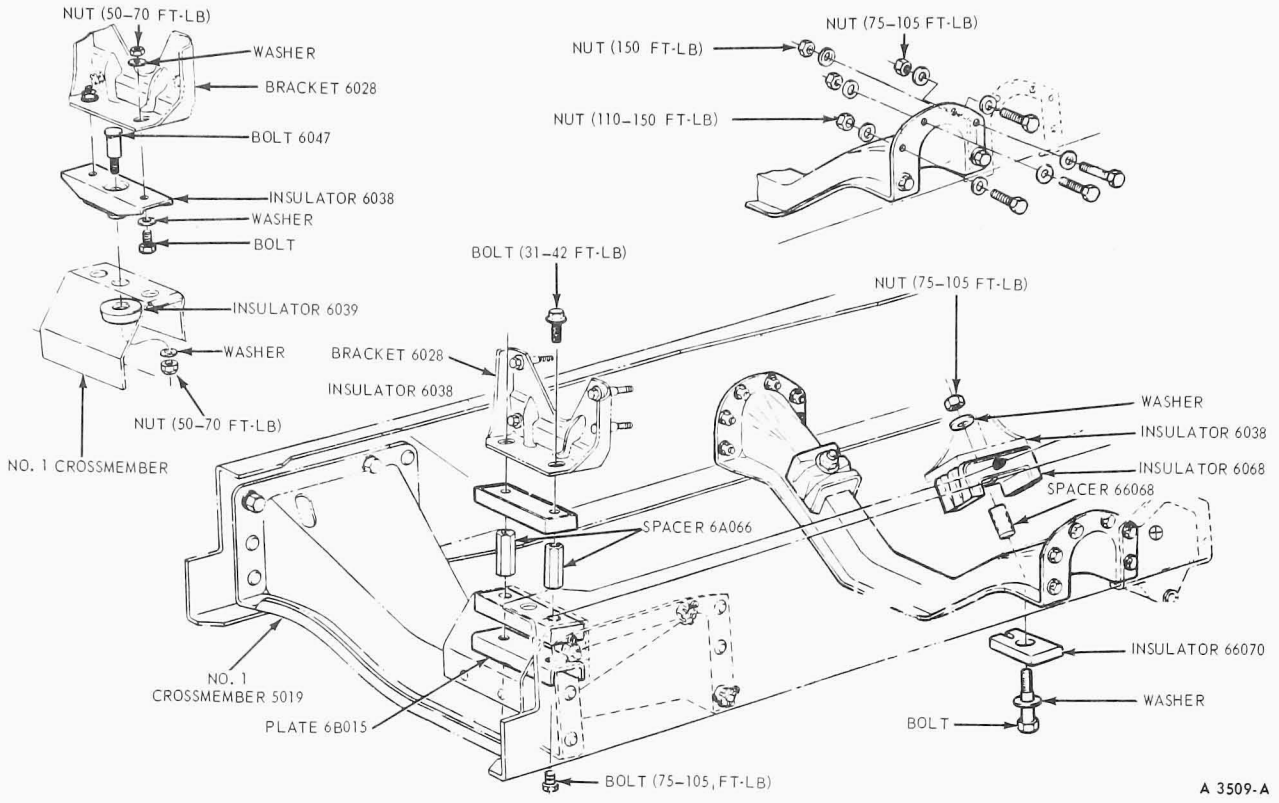

FIG. 7 Engine Supports — L, LT, LTS, LN, LNT-800

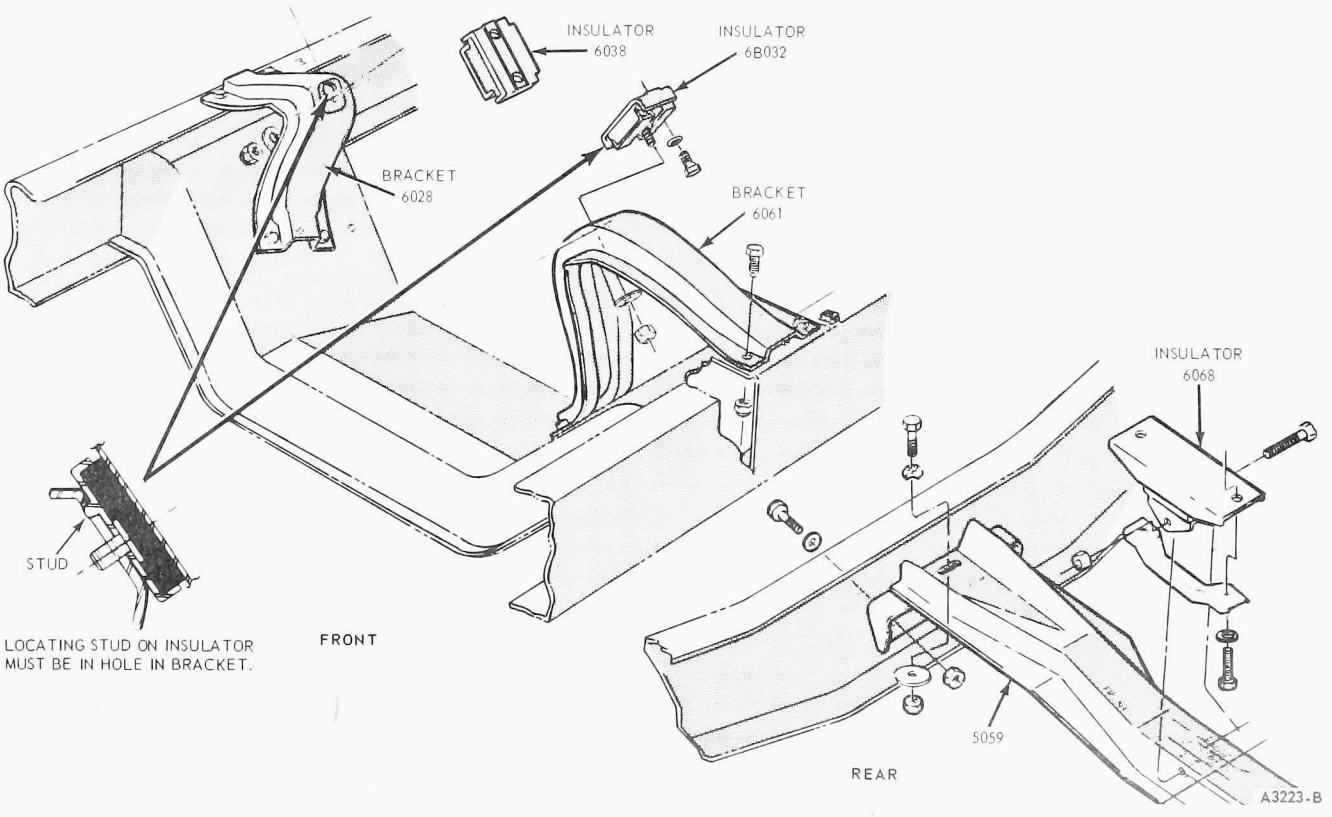

FIG. 8 Engine Supports — F350

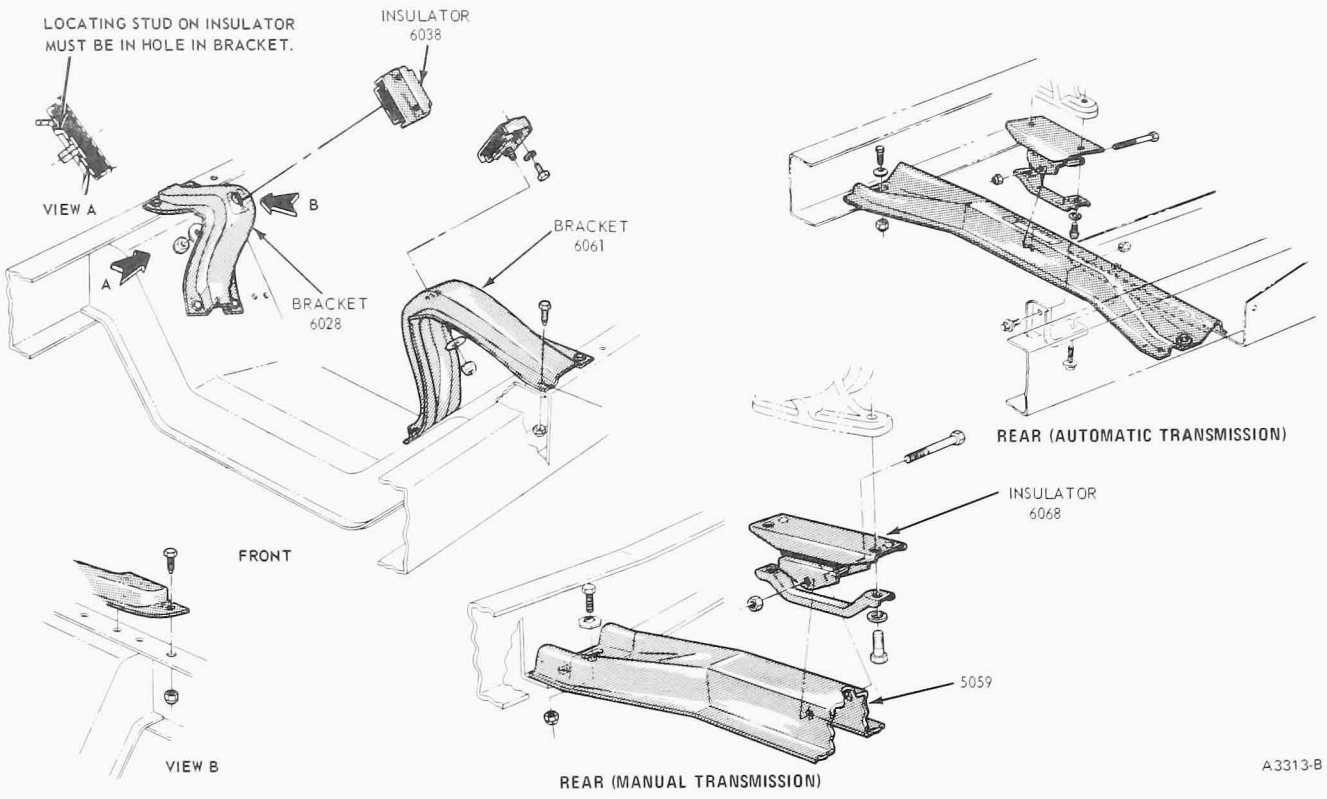

FIG. 9 Engine Supports — F-100-250

3. Remove the insulator-to-engine bolts and lock washers. Remove the insulator.

Installation

1. Position the insulator on the engine. Install the insulator-to-engine bolts and lock washers and torque to specifications.
2. Lower the engine carefully to make sure the insulator stud enters the support bracket mounting hole squarely and that the special locating stud is centered in the hole provided in the support bracket (Figs. 8 and 9).
3. Install the nut and lock washer on the insulator stud and torque the nut to specifications.

ENGINE REAR SUPPORTS

DOUBLE REAR TYPE

Typical engine rear supports are shown in Figs. 7 and 10.

Removal

1. Remove the nut, bolt, washers, lower insulator and spacer from each engine rear support.
2. Raise the rear of the engine with a jack and wood block placed under the transmission.
3. Remove the upper insulator from each rear support.

Installation

1. Position the upper insulators on the frame crossmember.
2. Lower the engine until the engine rear supports almost touch the upper insulators. Align the insulators with the supports. Install the spacers, lower insulators, bolts, nuts and washers, if used.
3. Lower the engine and remove the jack. Torque the nuts to specifications.
4. On all except the 330 MD engine, safety-wire the crossmember-to-clutch housing bolts.

SINGLE REAR TYPE

Removal

1. Remove the attaching bolts, nut and washer (Figs. 8 and 9).
2. Raise the transmission slightly to provide clearance, then remove the insulator and insulator retainer.

Installation

1. Position the insulator and retainer (Figs. 8 and 9) and install the insulator-to-extension housing bolts and lock washers.
2. Lower the transmission and install the insulator-to-frame crossmember bolt. Torque the nut and bolts to specifications.

CRANKCASE VENTILATION SYSTEM

Removal

1. Loosen or remove the hose clamps, and remove the vent hose from the air cleaner, if so equipped. Remove the air cleaner.
2. Grasp the crankcase ventilation regulator valve and pull it straight up and out of the grommet in the valve rocker arm cover fitting or oil filler cap.
3. In the same manner, remove the crankcase vent hose and elbow out of the other valve rocker arm cover. Remove the crankcase vent hose from the carburetor spacer. Separate the hoses from the regulator valve and elbow.

Refer to Part 21-01 for the Cleaning and Inspection procedures for the hoses, elbow, carburetor spacer and oil filler cap. **Do not clean the regulator valve. It should be replaced at the specified interval.**

Installation

1. Install the crankcase vent hose on the regulator valve. Install the hose

on the carburetor spacer inlet nipple.

2. Install the crankcase ventilation regulator valve in the valve rocker arm cover or oil filler cap. Be sure the grommet is properly seated around the regulator valve and valve rocker arm cover fitting on oil filler cap.
3. Install the hose on the elbow and insert the elbow into the retainer in the valve rocker arm cover.
4. Install the air cleaner and connect the crankcase vent hose.

VALVE ROCKER ARM COVER AND ROCKER ARM

Removal

1. Remove the air cleaner.
2. Disconnect the spark plug wires at the spark plugs. Remove the wires from the bracket on the valve rocker arm cover(s) and position the wires out of the way.

Remove the crankcase ventilation regulator valve and hose(s) from the valve rocker arm covers.

3. Remove the valve rocker arm cover(s).

If the left cover is removed, position the wiring harness to one side.

4. Starting at the No. 4 cylinder, loosen the right valve rocker arm shaft support bolts in sequence, two turns at a time. After the bolts are all loosened, remove the valve rocker arm shaft assembly and the oil baffle plate. Starting at the No. 5 cylinder, follow the same procedure on the left valve rocker arm shaft support bolts. **This procedure must be followed to avoid damage to the valve rocker arm shaft.**

Installation

1. Apply Lubriplate to the pad end of the rocker arms, to the tip of the valve stems, and to both ends of the push rods.
2. Crank the engine until the No. 1 piston is on TDC at the end of the compression stroke.
3. Rotate the crankshaft damper an additional 45 degrees.
4. Position the baffle plate and the valve rocker arm shaft assembly on the cylinder heads with the valve push rods in place and the rocker shaft support bolts fingertight. **Be sure the shaft is positioned so that the oil holes are to the bottom. Also, the identification notch on the end of the shaft (Fig. 11) must be face down and toward the front on the right bank, or toward the rear on the left bank.**
5. Starting at the No. 4 cylinder, tighten the bolts in sequence, two turns at a time, until the supports fully contact the cylinder head. Torque the bolts in sequence to specifications.
6. Starting at the No. 5 cylinder, follow the same procedure for the left valve rocker arm shaft support bolts. The additional time consumed in this procedure will permit the hydraulic lifters to leak down. This will minimize the possibility of bending the push rods, valves, or the rocker arms. **Be sure that the hydraulic lifters have leaked down to their normal operating position before cranking the engine. This is necessary in order to avoid possible damage to the valves, push rods, or valve rocker arms.**
7. Check the valve to rocker arm clearances and correct, as necessary, if any part of the valve train has been replaced (Part 21-01).
8. Clean the valve rocker arm cover(s). Place the new gaskets in the covers making sure that the tabs of the gasket engage the notches provided in the cover.
9. Position the cover(s) on the cylinder head(s). Make sure the gasket seats evenly all around the head. Install the bolts (and the wiring harness clamps on the left cover). The cover is tightened in two steps. First, torque the bolts to specifications. Two minutes later, torque the bolts to the same specifications.

Install the crankcase ventilation regulator valve and hose(s) on the valve rocker arm covers.

10. Connect the spark plug wires. Install the air cleaner and connect the crankcase vent hose.

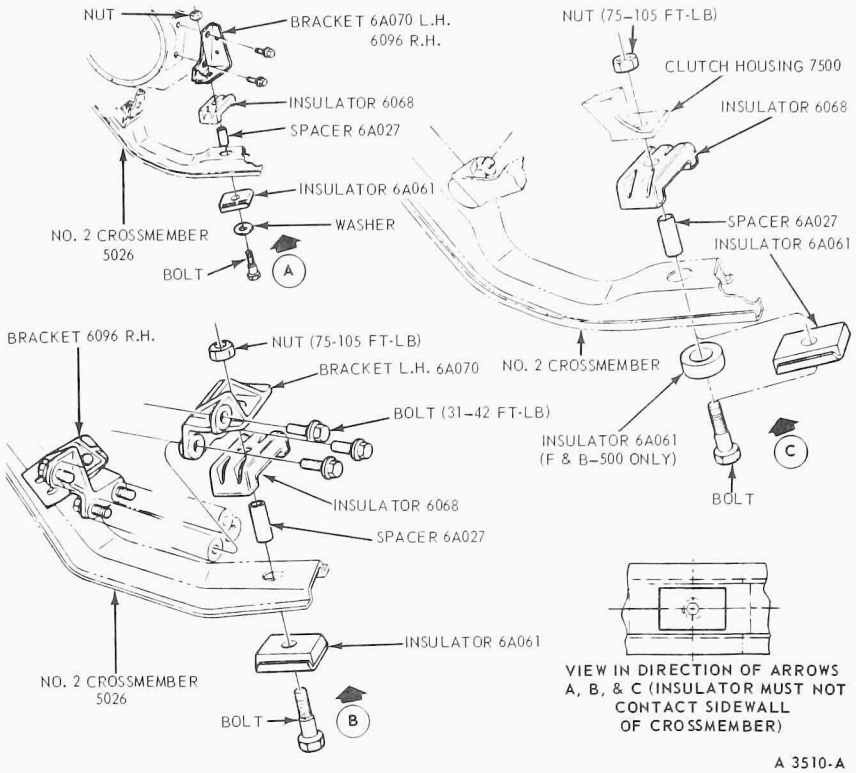

FIG. 10 Engine Rear Supports — F & B 500-750, C & LN-600-750, C & CT-800

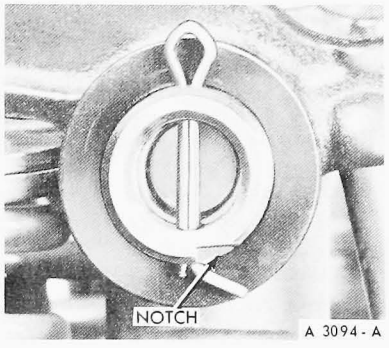

FIG. 11 Typical Installation Identification Mark — Rocker Arm Shaft Assembly

INTAKE MANIFOLD

Removal

1. Drain the cooling system. Remove

the air cleaner and crankcase vent hose(s).
2. Disconnect the accelerator rod at the carburetor. If applicable, remove the accelerator cross shaft bracket from the intake manifold and position it out of the way.
3. Remove the carburetor fuel inlet line. Disconnect the distributor vacuum line at the carburetor.
4. Disconnect the coil high-tension lead, and the coil wires at the coil. Disconnect the oil pressure sending unit wire at the sending unit. Remove the wiring harness from the retaining clips on the left valve rocker arm cover and position it out of the way.
5. Disconnect the spark plug wires at the spark plugs and remove the wires from the ignition harness brackets on the valve rocker arm covers.
6. Remove the distributor cap and spark plug wire assembly. Disconnect the distributor vacuum line at the distributor and remove the line.
7. Remove the distributor hold-down bolt and clamp. Remove the distributor.
8. Disconnect the radiator upper hose(s) at the water outlet housing. On a C-Series vehicle, disconnect the coolant supply tank hose at the water outlet housing. Disconnect the water temperature sending unit wire at the sending unit. Disconnect the heater hoses and position the hoses out of the way.
9. Disconnect the water pump by-pass hose(s) at the water pump.
10. Remove the valve rocker arm covers and crankcase vent hoses.
11. Refer to the procedures under Valve Rocker Arm Shaft Assembly Removal and remove the valve rocker arm shaft assembly.
12. Remove the valve push rods in sequence so that they can be installed in their original positions.
13. Remove the intake manifold attaching bolts.
14. Install standard eye bolts with 5/16-18 threads in the left front and right rear rocker arm cover threaded holes. Attach the engine lifting sling (Fig. 12).
15. Carefully remove the intake manifold. Remove the intake manifold gaskets and seals.
16. If the manifold is to be disassembled, remove the water pump by-pass hose(s), and the water outlet housing. Remove the carburetor, spacer and gasket. Remove the water temperature sending unit.

Refer to Part 21-01 for the cleaning and inspection procedures.

Installation

The intake manifold is shown in Fig. 13.

1. If the intake manifold was disassembled, install the carburetor, spacer and gasket making sure that the EGR spacer gasket is installed correctly. Install the water temperature sending unit, using electrical-conductive sealer. Coat the thermostat gasket with water-resistant sealer. Position the thermostat gasket on the intake manifold or on the water outlet housing. Install the thermostat and/or water outlet housing. Torque the bolts to specifications. Install the water pump by-pass hose.
2. Clean the mating surfaces of the intake manifold, cylinder heads and cylinder block. Use a suitable solvent to remove all traces of oil.
3. Coat the cylinder block seal surfaces with a quick-setting seal adhesive. Apply a non-hardening oil-resistant sealer to the mating lines of the cylinder heads and cylinder block.
4. Position new seals on the cylinder block and new gaskets on the cylinder heads. **Be sure the seals are properly positioned during installation as the adhesive sticks immediately on contact.** Position the manifold gasket slots over the end tabs on the seals (360 and 390 CID). Coat these four connections with a non-hardening sealer. Be sure the holes in the gaskets are aligned with the holes in the cylinder heads.
5. Install the eye bolts in the intake manifold, attach the engine lifting sling and carefully lower the intake manifold on the engine (Fig. 12).
6. Position the intake manifold by temporarily inserting the distributor in place. After the intake manifold is in place, run a finger around the seal area to make sure the seals are in place. If the seals are not in place, remove the intake manifold and reposition the seals.
7. Be sure the holes in the manifold gaskets and manifold are in alignment. Coat the underside of all attaching bolt heads with non-hardening oil-resistant sealer. Install the manifold attaching bolts and torque them to specifications in sequence as shown in Fig. 14. After the engine has been operated and reaches normal operating temperature, retorque the manifold bolts to specification.
8. Remove the distributor and the engine lifting sling and eye bolts.

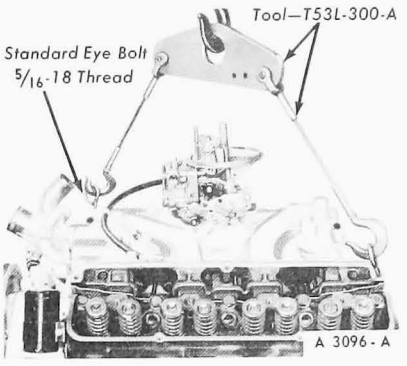

FIG. 12 Removing or Installing Intake Manifold — Typical

9. Connect the water pump by-pass hose to the water pump.
10. Connect the water temperature sending unit, and the radiator upper hose. On a C-Series vehicle, connect the coolant supply tank hose. Connect the heater hoses.
11. Apply Lubriplate to both ends of the push rods. Install the push rods in their original bores, positioning the lower ends of the rods in the lifter cups. Refer to the procedure under Valve Rocker Arm Shaft Assembly Installation and install the valve rocker arm shaft assembly.
12. Rotate the crankshaft damper until the No. 1 piston is on TDC at the end of the compression stroke. Position the distributor in the block with the rotor at the No. 1 firing position and the points open. Install the distributor hold-down clamp.
13. Clean the valve rocker arm covers. Place the new gaskets in the cover making sure that the tabs of the gasket engage the notches provided in the cover.
14. Install the valve rocker arm covers. The cover is tightened in two steps. First, torque the bolts to specifications. Two minutes later, torque the bolts to the same specifications.
15. Connect the crankcase ventilation hoses.
16. Install the carburetor fuel inlet line and the distributor vacuum line to the carburetor.
17. Install the distributor cap. Connect the spark plug wires. Install the wiring harness in the retaining clips on the left valve rocker arm cover.
18. Connect the oil pressure sending unit wire, the coil high-tension lead, and the coil primary wire.
19. If applicable, install the accelerator cross shaft bracket. Connect the accelerator rod.
20. Fill and bleed the cooling system.

21. Install the air cleaner and vent hose; then start the engine and check and adjust the ignition timing. Connect the distributor vacuum line to the distributor. Operate the engine until engine temperatures have stabilized and adjust the engine idle speed and idle fuel mixture. Retorque the manifold bolts to specification.

EXHAUST MANIFOLDS

Removal

1. Remove the air cleaner. Disconnect the exhaust manifold(s) at the muffler pipe(s).
2. Disconnect the power steering pump bracket from the cylinder block and move it out of the way. Position the pump so that the oil will not drain out.
3. Remove the dipstick and tube assembly.
4. Remove the attaching bolts and tab washers, then remove the exhaust manifolds.

Installation

1. Refer to Part 21-01 for the cleaning and inspection procedures; then clean the mating surfaces of the exhaust manifold and cylinder head. Scrape the gasket material from the mounting flange of the exhaust manifold and muffler inlet pipe.
2. Apply graphite grease to the mating surface of the exhaust manifold.
3. Position the exhaust manifold on the cylinder head and install the attaching bolts and tab washers. Working from the center to the ends, torque the bolts to specifications. Lock the bolts by bending one tab of the washer over a flat on the bolt.
4. Install the dipstick and tube assembly.
5. Position the power steering pump bracket on the cylinder block and install the attaching bolts. Adjust the belt tension. Position the hoses and install the power steering hose bracket.
6. Position a new gasket on the muffler inlet pipe and connect the exhaust manifold to the inlet pipe. Install and torque the attaching nuts to specifications.
7. Install the air cleaner.

CYLINDER HEADS

Removal

1. Remove the intake manifold and carburetor as an assembly, following the procedure under Intake Manifold Removal.
2. Disconnect the exhaust manfolds at the muffler inlet pipes.

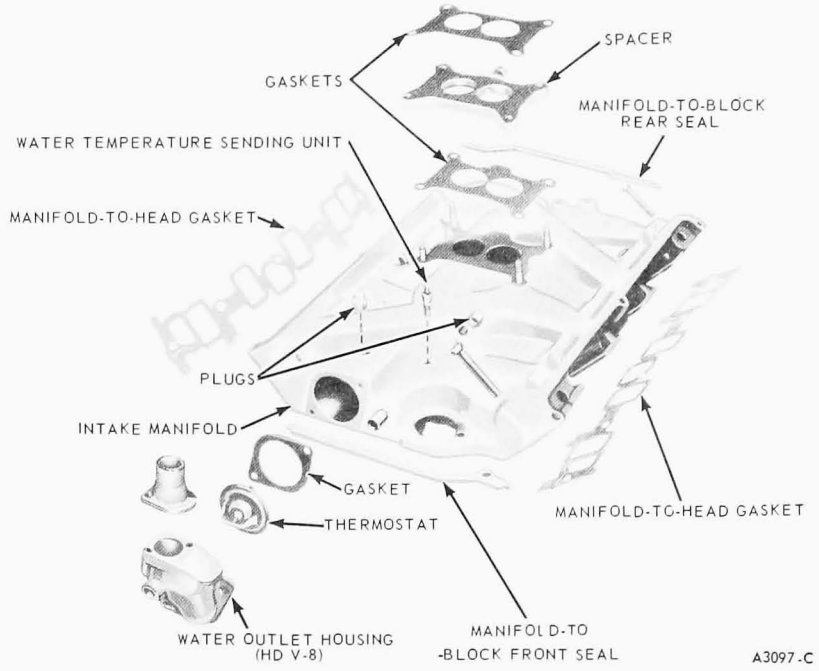

FIG. 13 Typical Intake Manifold Assembly

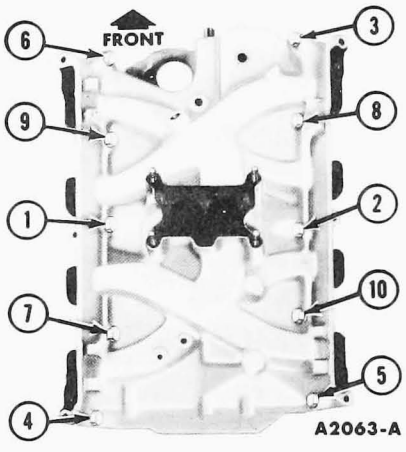

FIG. 14 Intake Manifold Torque Sequence

If the left cylinder head is to be removed, remove the ignition coil.

3. Remove the cylinder head bolts and lift the cylinder heads off the block. **Do not pry between the head and the block.** Remove and discard the cylinder head gasket.

Installation

1. Clean the cylinder head and cylinder block gasket surfaces.
2. Check the flatness of the cylinder head and block gasket surfaces (Part 21-01).
3. Guided by the word **front** on the gasket, install the gasket over the cylinder head dowels.
4. Place the cylinder head on the engine.
5. Oil the threads of the cylinder head bolts, and install the bolts. The cylinder head bolts are tightened in three progressive steps. Torque all the bolts in sequence (Fig. 15) to specifications. When the cylinder head bolts have been tightened, as detailed in this procedure, it is not necessary to retorque the bolts after extended operation.
6. Position new gaskets on the muffler inlet pipes. Connect the exhaust manifolds to the muffler inlet pipes. Torque the nuts to specifications.
7. Install the intake manifold and related parts, following the procedure under Intake Manifold Installation.

VALVE SPRING, RETAINER AND STEM SEAL

Broken valve springs, or worn valve stem seals and retainers may be replaced without removing the cylinder head, providing damage to the valve or valve seat has not occured.

Removal

1. Remove the air cleaner. Remove the valve rocker arm cover(s), following the procedure under Valve Rocker Arm Shaft Assembly Removal.
2. Loosen the valve rocker arm support bolts evenly and alternately, two turns at a time, until the valve spring tension has been released. Remove the push rods of the cylinder to be serviced.

3. Tighten the valve rocker arm support bolts evenly and alternately, two turns at a time, until they are snug. Push the rocker arm to one side and secure it in this position (Fig. 16). If an end valve is to be worked on, it will be necessary to remove the rocker arm from the shaft.
4. Install an air adapter to the spark plug hole and connect the air supply hose to the adapter. Turn on the air supply. **Air pressure may turn the crankshaft until the piston reaches the bottom of its stroke.**
5. Compress the valve spring and remove the valve retainer locks from the valve (Fig. 16). **If air pressure fails to hold the valve in the closed position during this operation, it can be presumed that the valve is not seating or is damaged. If this condition occurs, remove the cylinder head for further inspection.**
6. Remove the valve spring and related parts. Remove the valve stem oil seal (Fig. 17). **If air pressure had forced the piston to the bottom of the cylinder, any removal of air pressure will allow the valve(s) to fall into the cylinder. A rubber band, tape or string wrapped around the end of the valve stem will prevent this condition and still allow enough travel to check the valve for binds.**
7. Remove the air supply hose (or bleed the air pressure), and inspect the valve stem for damage. Rotate the valve and check the valve stem tip for eccentric movement during rotation. Move the valve up and down through normal travel in the valve guide and check the stem for binds. **If the valve has been damaged, it will be necessary to remove the cylinder head for repairs.**
8. If the condition of the valve is satisfactory, hold the valve in the closed position and apply air pressure within the cylinder.

Installation

1. Oil the valve stem and install a new seal. Do not install the O-ring type seal on the exhaust valve at this time (330, 361 HD and 391 HD only).
2. Install the valve spring over the valve.

LD engines use a damper spring in conjunction with the valve spring. Use a positive rotating spring retainer on the exhaust valves of all MD and HD engines.

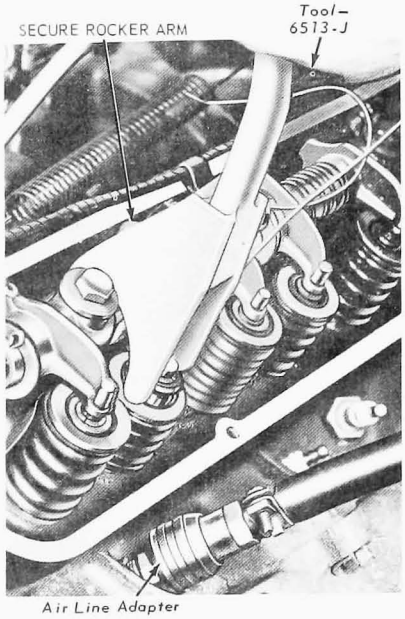
3. Compress the spring (Fig. 16). If working on a HD engine, apply SE engine oil to the O-ring type seal, then install it on the exhaust valve. Make sure the seal is seated in the groove to avoid damage when the valve spring is released. Install the retainer locks and remove the spring compressor.

Tap the valve stem tip with a soft mallet to make certain that the retainer locks are properly seated.

4. Remove the air line and adapter. Install the spark plug. Remove the wire securing the valve rocker arm and slide the rocker arm into position. Install the end rocker arm(s), if they were removed.
5. Loosen the valve rocker arm support bolts evenly and alternately, two turns at a time, until spring tension is removed. Apply Lubriplate to the pad end of the rocker arm, the tip of the valve stem and to both ends of the push rod. Position the push rod within the rocker arm socket and the valve lifter seat.
6. Tighten the rocker arm shaft support bolts evenly and alternately, two turns at a time, until they are snug. Torque the bolts to specifications.
7. Install the high-tension lead wire in the ignition coil terminal. Install the spark plug wires.
8. Install the valve rocker arm cover(s), following the procedure under Valve Rocker Arm Shaft Assembly Installation.
9. Install the air cleaner.

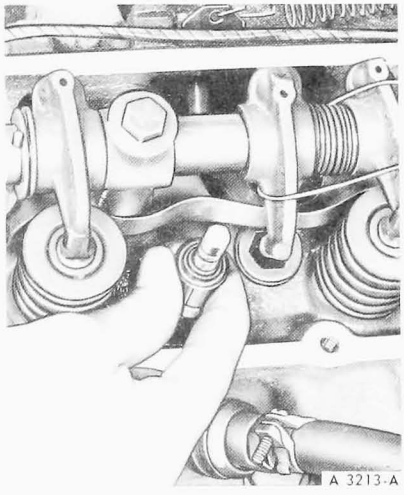
A2068-A

FIG. 15 Cylinder Head Bolt Torque Sequence



A 3099-A

FIG. 16 Compressing Valve Spring — In Chassis



A 3213-A

FIG. 17 Removing Intake Valve Stem Seal

VALVE LIFTER

The following procedure is applicable for removing one or all of the valve lifters. Before replacing a hydraulic valve lifter for noisy operation, be sure the noise is not caused by improper valve clearance or by worn rocker arms or push rods.

Removal

1. Refer to Valve Rocker Arm Shaft Assembly Removal, and remove the valve rocker arm covers and valve rocker arm shaft assemblies.
2. Remove the lifters with tool T70P-14151 through the push rod

openings (Fig. 18). In some cases, it will be necessary to transfer the lifter to an adjoining opening in order to remove it. Place the lifters in a rack so that they can be installed in their original positions.

The internal parts of each hydraulic valve lifter assembly are matched sets. Do not intermix the parts. Keep the assemblies intact until they are to be cleaned.

Installation

1. Lubricate the new (or cleaned) hydraulic valve lifters with heavy SE engine oil and install them through the push rod openings with the lifter removal tool (Fig. 18). Install the push rods in their original positions.
2. Refer to Valve Rocker Arm Shaft Assembly Installation and install the valve rocker arm shaft assemblies, and rocker arm covers.

WATER PUMP

330 MD, 360 AND 390 CID ENGINES

Removal

1. Drain the cooling system. Loosen the alternator adjusting arm bolt and remove the drive belt(s).
2. Remove the fan, spacer and pulley.
3. Disconnect the radiator lower hose, heater hose and the water by-pass hose at the water pump.
4. Remove the bolts attaching the water pump to the block; then remove the pump and gaskets.

Installation

Before a water pump is reinstalled, check it for damage. If it is damaged and requires repair, replace it with a new pump or install a rebuilt pump obtained from a Ford-Authorized Reconditioner.

1. Clean the gasket surfaces of the water pump and cylinder block.
2. Apply water-resistant sealer to both sides of new gaskets and position the gaskets on the water pump outlets.
3. Position the pump body on the block and install the pump attaching bolts. Torque the bolts to specifications.
4. Install the fan, spacer and pulley. Install the drive belt(s) and adjust the tension to specifications. Connect the radiator lower hose, heater hose and water by-pass hose to the water pump. Fill and bleed the cooling system. Operate the engine and check for coolant leaks.

330 HD, 361 AND 391 CID ENGINES

Removal

1. Drain the cooling system. Loosen and remove the drive belt(s).
2. On engines with water-pump mounted fans, remove the fan, spacer and pulley. Let the fan blade rest down in the shroud. On high-fan engines, remove the fan and bracket assembly. On low-fan engines, remove the bolts securing the fan assembly to the crankshaft damper. Remove the fan assembly.

On a vehicle with an air compressor, remove the attaching bolts and position the compressor on the frame rail. Remove the air compressor mounting bracket.

On vehicles with power steering, remove the power steering pump and position it to one side, leaving the hoses attached.

3. Disconnect the radiator lower hose, heater hose and the water by-pass hose at the water pump.
4. Remove the bolts attaching the pump to the cylinder block; then remove the pump and gasket.

Installation

Before a water pump is reinstalled, check it for damage. If it is damaged and requires repair, replace it with a new pump or install a rebuilt pump obtained from an authorized reconditioner.

1. If a new pump is to be installed, remove the fittings from the old pump and install them on the new pump. Clean the gasket surfaces of the water pump and cylinder block.
2. Coat both sides of the new gaskets with water-resistant sealer and position them on the block. Install the water pump and torque the attaching bolts to specifications.
3. Connect the radiator lower hose, heater hose and the water by-pass hose to the water pump.

On a vehicle with an air compressor, install the air compressor bracket and air compressor.

On vehicles with power steering, position the power steering pump to the engine and install the attaching bolts.

4. Install the fan, spacer and pulley. On high-fan engines, install the fan and bracket assembly. On low-fan engines, install the fan assembly on the crankshaft damper. Install the drive belt(s) and adjust the tension to specifications.
5. Fill and bleed the cooling system. Operate the engine until normal operating temperature is reached. Check the coolant level in the radiator. Check for coolant leaks.

CYLINDER FRONT COVER AND TIMING CHAIN

Removal

If the cylinder front cover is being removed to replace the gasket or to replace the fuel pump drive eccentric, it is not necessary to check the timing chain deflection. For cylinder front cover gasket replacement, it is not necessary to remove the timing chain and sprockets.

1. Drain the cooling system and the crankcase. Remove the air cleaner. Disconnect the battery ground cable, and disconnect the distributor vacuum line.
2. Disconnect the radiator upper hose at the water outlet housing. Disconnect the radiator lower hose at the water pump.
3. Disconnect the transmission oil cooler lines, if so equipped. Remove the radiator and support as an assembly. If equipped with an automatic radiator shutter, leave it attached to the radiator assembly.
4. Disconnect the heater hose at the water pump. Remove the water pump by-pass hose(s).

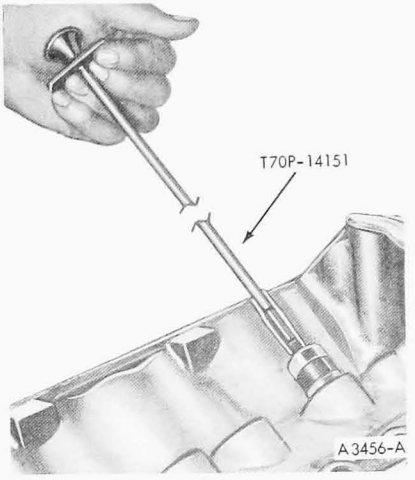


FIG. 18 Removing Valve Lifter

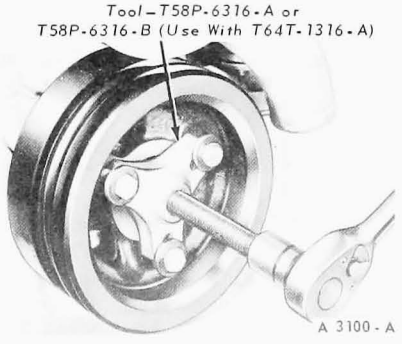

FIG. 19 Removing Crankshaft Damper

On a high-fan installation, remove the cooling fan and drive belt.

5. Remove the power steering pump and position it to one side, leaving the hoses attached.
6. If equipped with an air compressor, disconnect the air lines, and remove the air compressor.
7. Remove the alternator adjusting arm bolt at the alternator. Remove the drive belts. Disconnect the wires and remove the alternator from the support bracket. Remove the water pump and cooling fan drive belts. Remove the water pump and fan as an assembly. On a C-Series vehicle, remove the cooling fan from the crankshaft damper.
8. Remove the cap screw and washer from the end of the crankshaft. Install the puller on the crankshaft damper (Fig. 19) and remove the damper.
9. Disconnect the carburetor fuel inlet line at the fuel pump.
10. Remove the fuel pump attaching bolts and lay the pump to one side with the flexible fuel line still attached.
11. Remove the crankshaft sleeve as shown in Fig. 20.
12. Remove the bolts that attach the cylinder front cover to the cylinder block and to the oil pan. Using a thin blade knife, cut the oil pan gasket flush with the cylinder block face prior to separating the cover from the block. Remove the cylinder front cover, alternator support bracket and adjusting arm bracket and the engine front support bracket.
13. Discard the cylinder front cover gasket. Remove the oil slinger.
14. Check the timing chain deflection by following the procedure in Part 21-01.
15. Check the camshaft end play, following the procedure in Part 21-01.
16. Crank the engine until the timing marks on the sprockets are positioned as shown in Fig. 21.
17. Remove the camshaft sprocket cap screw and the fuel pump eccentric.
18. Slide both sprockets and the timing chain forward, and remove the sprockets and timing chain as an assembly (Fig. 22).

Installation

1. Refer to Part 21-01 for the cleaning and inspection procedures. Clean the crankshaft damper, following the referenced procedures.
2. Position the sprockets and timing chain on the camshaft and crankshaft (Fig. 22). Be sure the timing marks on the sprockets are positioned as shown in Fig. 21.
3. Install the fuel pump eccentric and the camshaft sprocket cap screw (Fig. 23). Torque the sprocket cap screw to specifications. **If a new thrust plate was installed on the camshaft to bring end play within specifications, check the end play (Part 21-01).** Install the crankshaft front oil slinger.
4. Clean all oil pan and cylinder block-to-front cover gasket surfaces.
5. Coat the gasket surface of the oil pan with sealer. Cut and position the required section of a new gasket on the oil pan. Apply sealer at the corners.
6. Coat the gasket surfaces of the block and cover with sealer, and position a new gasket on the block.
7. Position the cylinder front cover on the cylinder block. **Use care when installing the cover to avoid sealer damage or possible gasket mislocation.**
8. Install the cylinder front cover-to-seal alignment tool into proper position. It may be necessary to force the cover downward to slightly compress the pan gasket. This operation can be facilitated by using a suitable tool at the cover attaching hole locations in the cylinder block (Fig. 24). Position the engine front support bracket and alternator mounting bracket and adjusting arm bracket on the cylinder front cover. Install the screws.
9. While pushing in on the pilot, align the oil pan gasket surfaces of the cylinder front cover and cylinder block, and torque the screws to specifications. Remove the pilot.
10. Clean the oil seal rubbing surface on the crankshaft sleeve with solvent and polish with crocus cloth. Examine for grooves, nicks and burrs which could damage the seal. Lubricate the seal rubbing surface with grease and install the crankshaft sleeve.
11. Lubricate the damper hub and line up the damper keyway with the key on the crankshaft. Install the damper on the crankshaft (Fig. 25).
12. Install the damper cap screw and washer, and torque the screw to specifications.
13. Install the power steering pump pulley on the damper. Torque the screws to specifications.
14. Clean the water pump gasket surfaces. Coat new gaskets with water-resistant sealer and position the gaskets on the cylinder block. Install the water pump and fan assembly. Torque the attaching bolts to specifications.

    On a C-Series vehicle, install the

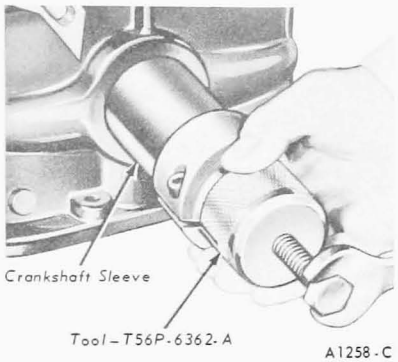

FIG. 20 Removing Crankshaft Sleeve

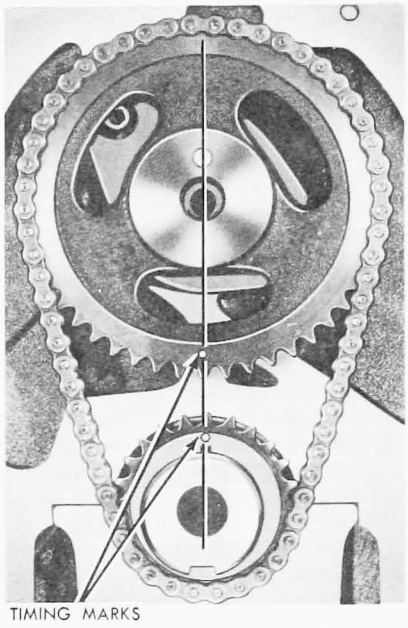

FIG. 21 Aligning Timing Marks

cooling fan on the crankshaft damper.

15. Install and adjust the alternator and water pump drive belt(s).
16. Install the power steering pump and drive belt. Adjust the drive belt tension.

If equipped with an air compressor, install the compressor and connect the air lines. Install the drive belt and adjust the tension to specifications.

On a high-fan installation, install the fan and drive belt and adjust the tension to specifications.

17. Install the fuel pump, using a new gasket.
18. Connect the carburetor fuel inlet line. Connect the heater hose to the water pump. Install the water pump by-pass hose and tighten the hose clamps.
19. Install the radiator, radiator support, and shutter (if so equipped) as an assembly. Connect the radiator lower hose at the water pump and the radiator upper hose at the coolant outlet housing. Connect the battery ground cable. Connect transmission oil cooler lines, if so equipped.
20. If any of the coolant has entered the oil pan when separating the cylinder front cover from the block, the crankcase oil should be drained and refilled with the proper grade and quantity of engine oil before starting the engine.
21. Fill and bleed the cooling system.
22. Install the air cleaner and operate the engine at fast idle to check for coolant and oil leaks. Adjust the ignition timing and connect the distributor vacuum line.

FRONT OIL SEAL

It is good practice to replace the oil seal each time the cylinder front cover is removed.

Removal

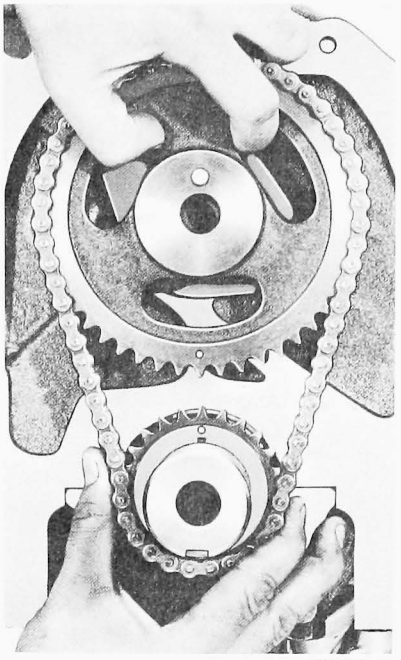
1. Remove the cylinder front cover.
2. Drive out the old seal with a pin punch. Clean out the recess in the cover.

Installation

1. Coat a new seal with grease, then position the seal in the cylinder front cover.
2. Position the seal installer and drive the seal into the cover until it is fully seated in the recess (Fig. 26).
3. Check the seal after installation to be sure that the spring is properly positioned in the seal.

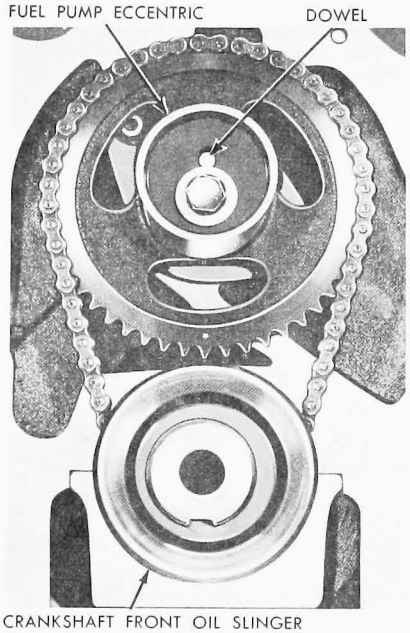
CAMSHAFT

The camshaft and related parts are shown in Fig. 27.



A2075-A

FIG. 22 Removing or Installing Timing Chain



A2076-A

FIG. 23 Fuel Pump Eccentric

Removal

1. Remove the cylinder front cover, following the steps under Cylinder Front Cover and Timing Chain Removal.
2. Refer to Valve Rocker Arm Shaft Assembly Removal and remove the valve rocker arm covers and the valve rocker arm shaft assemblies.
3. Remove the intake manifold and baffle plate, following the procedures under Intake Manifold Removal.
4. Remove the valve lifters in sequence and place them in a rack so that they can be installed in their original locations.
5. Remove the timing chain and sprockets, following the procedures under Cylinder Front Cover and Timing Chain Removal.
6. Remove the camshaft thrust plate. Carefully remove the camshaft by pulling it toward the front of the engine. **Use caution to avoid damaging the camshaft bearing.**

Refer to Part 21-01 for the cleaning and inspection procedures.

Installation

1. Oil the camshaft bearing journals and apply Lubriplate to the lobes. Carefully slide the camshaft through the bearings. Install the thrust plate (Fig. 28).
2. Position the sprockets and timing chain on the camshaft and crankshaft (Fig. 22) with the timing marks on the sprockets aligned as shown in Fig. 21.
3. Install the fuel pump eccentric and the camshaft sprocket cap screw (Fig. 23). Torque the sprocket cap screw to specifications. Install the front oil slinger.
4. **Check the camshaft end play as outlined in Part 21-01. If the end play is excessive,** replace the thrust plate.
5. Replace the crankshaft front oil seal. Install the cylinder front cover, crankshaft damper, and related parts following the procedure under Cylinder Front Cover and Timing Chain Installation.
6. Lubricate the valve lifters with heavy SE engine oil and install them in the bores from which they were removed. Lubricate each end of the push rods with Lubriplate or equivalent and install them in their original positions.
7. Install the intake manifold and baffle plate, following the procedures under Intake Manifold Installation.
8. Refer to Valve Rocker Arm Shaft Assembly Installation and install the valve rocker arm shaft assembly.
9. With the No. 1 piston on TDC at the end of the compression stroke, position the distributor in the block with the rotor at the No. 1 firing position and the points open. Install the hold-down clamp.
10. Install the distributor cap. Connect the coil high-tension lead.
11. Fill and bleed the cooling system.

12. Start the engine, then check and adjust the ignition timing. Connect the distributor vacuum line. Operate the engine at fast idle and check all hose connections and gaskets for leaks.

FLYWHEEL

Removal

1. Disconnect the transmission from the engine and slide it to the rear as outlined in Group 16 (standard transmission) or Group 17 (automatic transmission).
2. Remove the flywheel attaching bolts and remove the flywheel.

Refer to Part 21-01 for the cleaning and inspection procedures.

To check flywheel face runout or replace flywheel ring gear, refer to Part 21-01.

Installation

1. Install the flywheel on the crankshaft flange, apply oil-resistant sealer to the threads and install the attaching bolts. Torque the bolts, in sequence across from each other, to specifications.
2. Check the flywheel runout, following the procedure in Part 21-01.
3. Connect the transmission to the engine as outlined in Group 16 (standard transmission) or Group 17 (automatic transmission).

CLUTCH PILOT BUSHING

Inspection procedures are outlined under Crankshaft Cleaning and Inspection in Part 21-01.

Removal

1. Disconnect the transmission from the engine and slide it to the rear as outlined in Group 16.
2. Remove the pressure plate and cover assembly and the clutch disc as outlined in Group 16.
3. Remove the pilot bushing (Fig. 29).

Installation

1. Coat the pilot bushing bore in the crankshaft with a small quantity of wheel bearing lubricant. Avoid using too much lubricant as it may be thrown onto the clutch disc when the clutch rotates.
2. Install the pilot service bearing (Fig. 30).
3. Install the clutch disc and the pressure plate assembly as outlined in Group 16.
4. Connect the transmission to the engine as outlined in Group 16.

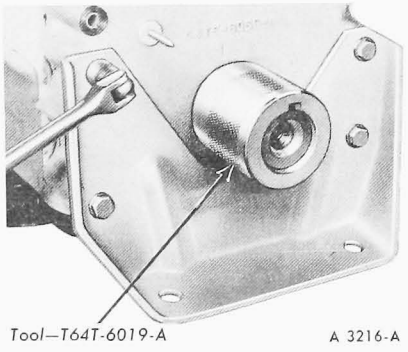


FIG. 24 Aligning Cylinder Front Cover

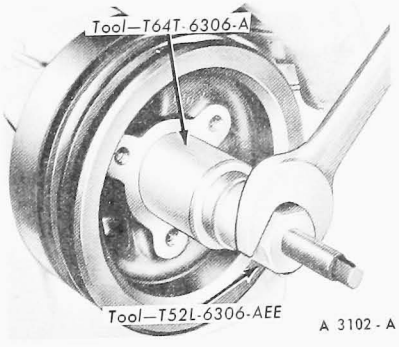

FIG. 25 Installing Crankshaft Damper

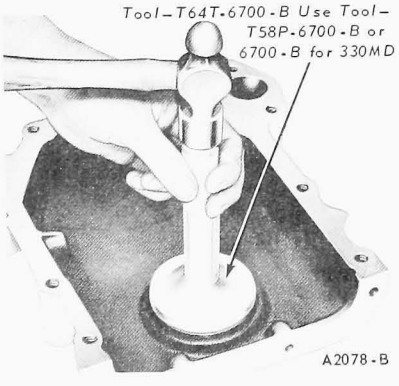

FIG. 26 Installing Front Oil Seal

CAMSHAFT REAR BEARING BORE PLUG

Removal

1. Remove the transmission, following the procedure in Group 16 (standard transmission) or Group 17 (automatic transmission).
2. Remove the flywheel housing. Remove the flywheel attaching bolts and remove the flywheel. Remove the engine rear cover plate.
3. Follow the instructions in Part 21-01 under Core Plug Replacement to install the plug.

Installation

1. Install the engine rear cover plate. Install the flywheel. Install the flywheel housing.
2. Install the transmission, following the procedures in Group 16 (standard transmission) or Group 17 (automatic transmission).

OIL PAN AND OIL PUMP

Removal

1. Drain the crankcase and remove the oil level dipstick and the dipstick tube.
2. Remove the oil pan attaching bolts and lower the oil pan to the axle. Position the crankshaft so that the counterweight will clear the oil pan.
3. Remove the oil pump and the inlet tube attaching bolts. Place the oil pump, inlet tube screen and intermediate drive shaft in the oil pan. Remove the oil pan and oil pump.

Refer to Part 21-01 for the cleaning and inspection procedures.

Installation

1. Clean the oil pan and block gasket surfaces. Position a new gasket on the oil pan.
2. Remove the inlet tube screen from the oil pump. Clean the oil pump and inlet tube screen. Position a new oil pump inlet tube gasket on the oil pump and install the inlet tube. Prime the oil pump by filling the inlet port with engine oil. Rotate the pump shaft to distribute the oil within the pump body.
3. Place the oil pump in the oil pan and position the oil pan on the crossmember. Position a new oil pump gasket on the cylinder block. Insert the intermediate drive shaft into the oil pump housing and install the oil pump and shaft as an assembly (Fig. 31). **Do not attempt to force the pump into position if it will not seal readily. The drive shaft hex may be misaligned with the distributor shaft.** To align, rotate the intermediate shaft into a new position. Torque the oil pump and inlet tube attaching bolts to specifications.
4. Hold the oil pan in place against the cylinder block and install an

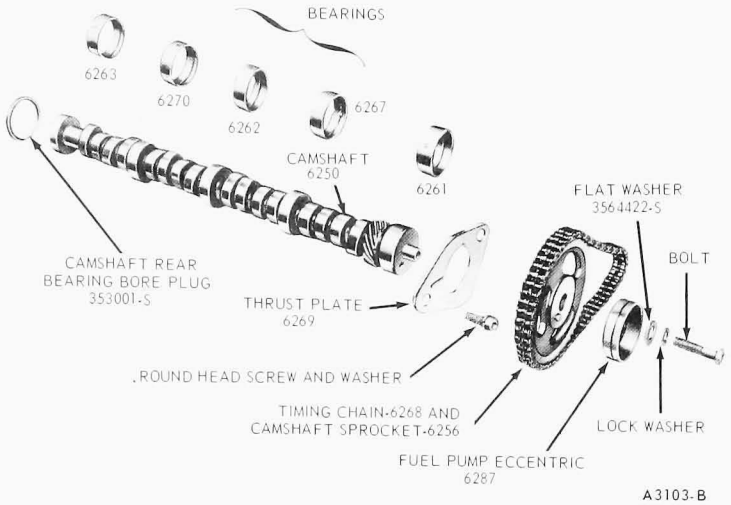

FIG. 27 Camshaft and Related Parts

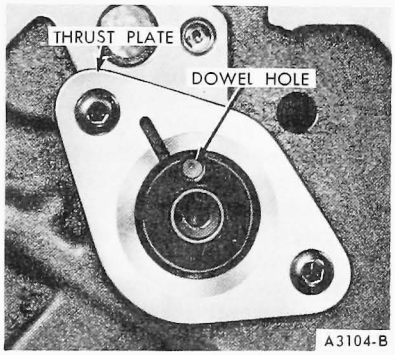

FIG. 28 Camshaft Thrust Plate Installed

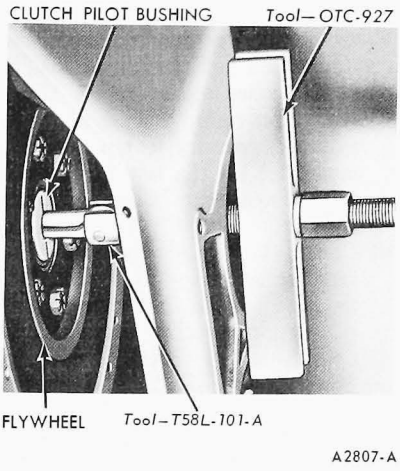

FIG. 29 Removing Clutch Pilot Bushing

attaching bolt on each side of the oil pan. Install the remaining screws, and torque them, from the center outward, to specifications. Install the dipstick tube and dipstick.

5. Replace the engine oil filter element. Fill the crankcase with the proper grade and quantity of engine oil. Operate the engine and check for leaks.

CRANKSHAFT REAR OIL SEAL

Replacement of a crankshaft rear oil seal to correct for oil leaks requires replacement of both the upper and lower seals, as follows:

Removal

1. Remove the oil pan and oil pump (as required), following the procedures in this Section.
2. Loosen all the main bearing cap bolts, thereby lowering the crankshaft slightly but not to exceed 1/32 inch.
3. Remove the rear main bearing cap, and remove the oil seal from the bearing cap and cylinder block. On the block half of the seal, install a small metal screw in one end of the seal and pull on the screw to remove the seal. **Exercise caution to prevent scratching or damaging the crankshaft seal surfaces.**

Installation

1. Carefully clean the seal grooves in the cap and block with a brush and solvent.
2. Dip the seal halves in clean engine oil.
3. Carefully install the upper seal (cylinder block) into its groove with the lip of seal toward the FRONT of the engine (Fig. 32), by rotating it on the seal journal of the crankshaft until the seal protrudes approximately 3/8 inch below the parting surface.

Be sure no rubber has been shaved from the outside diameter of the seal by the bottom edge of the groove.

4. Tighten the remaining bearing cap bolts and torque to specifications.
5. Install the lower seal in the rear main bearing cap with undercut side of seal toward the FRONT of the engine (Fig. 32). Allow the seal to protrude approximately 3/8 inch

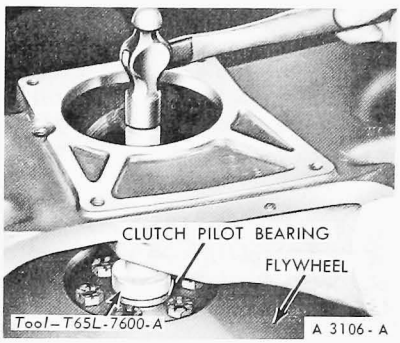

FIG. 30 Installing Clutch Pilot Bearing

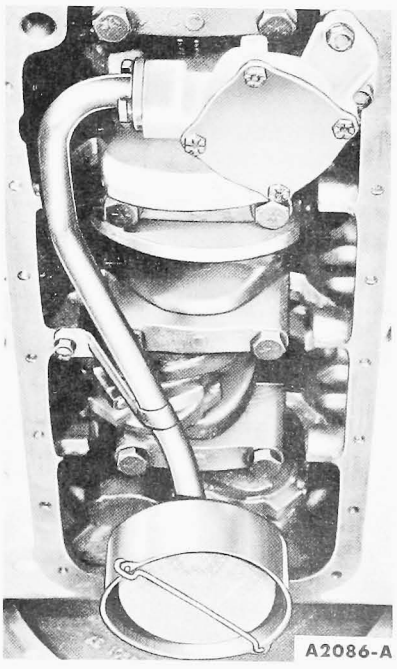

FIG. 31 Oil Pump and Inlet Tube Installed—Typical

above the parting surface to mate with the upper seal when the cap is installed.

6. Apply a thin coating of oil-resistant sealer to the rear main bearing cap at the rear of the top mating surface. **Do not apply sealer to the area forward of the side seal groove. Install the rear main bearing cap. Torque the cap bolts to specifications.**
7. Dip the side seals in light engine oil, then immediately install them in the grooves. Do not use sealer on the side seals. **The seals are designed to expand when dipped in oil. Using sealer may retard this expansion.** It may be necessary to tap the seals into place for the last 1/2 inch of travel. Do not cut the seal projecting ends.
8. Check the retainer side seals for leaks by squirting a few drops of oil into the parting lines between the rear main bearing cap and the cylinder block from the outside. Blow compressed air against the seals from the inside of the block. If air bubbles appear in the oil, it indicates possible oil leakage. **This test should not be performed on newly installed seals until sufficient time has been allowed for the seals to expand into the seal grooves.**
9. Install the oil pump and oil pan. Install the oil level dipstick. Fill the crankcase with the proper amount and viscosity oil.
10. Operate the engine and check for oil leaks.

MAIN BEARING

The main bearing inserts are selective fit. Refer to the procedures under Fitting Main and Connecting Rod Bearings in Part 21-01.

Removal

1. Drain the crankcase. Remove the oil level dipstick. Remove the oil pan and oil pump. Remove the spark plugs to allow easy rotation of the crankshaft.
2. **Replace one bearing at a time leaving the other bearings securely fastened.** Remove the main bearing cap to which new bearings are to be installed.
3. Insert the upper bearing removal tool (Tool 6331-E) in the oil hole in the crankshaft.
4. Rotate the crankshaft in the direction of engine rotation to force the bearing out of the block.
5. Clean the crankshaft journal and bearing inserts. Refer to Part 21-01 for the recommended cleaning and inspection procedures.

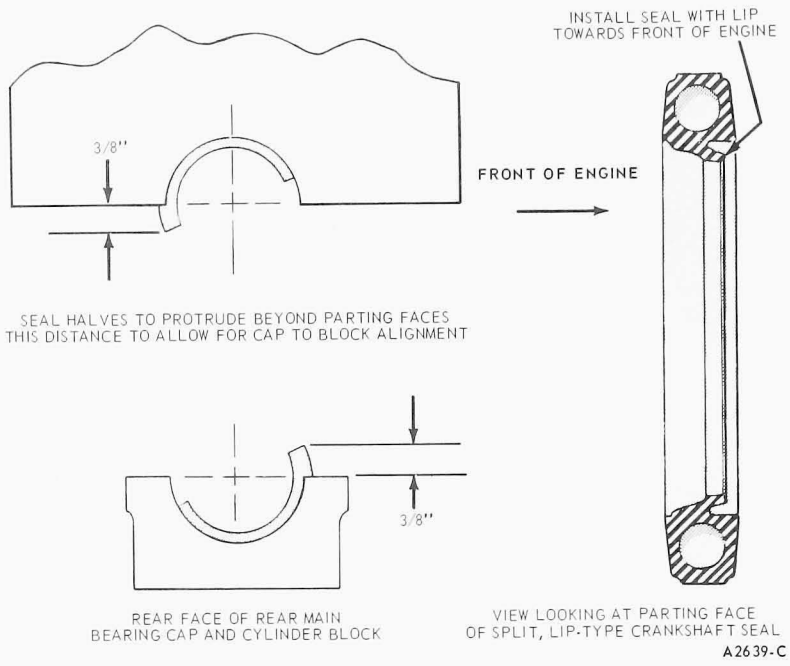

FIG. 32 Installing Crankshaft Rear Seal

Installation

1. Place the plain end of the bearing over the shaft on the locking tang side of the block and partially install the bearing so that tool 6331-E can be inserted in the oil hole in the crankshaft. With tool 6331-E positioned in the oil hole in the crankshaft, rotate the crankshaft in the opposite direction of engine rotation until the bearing seats itself. Remove the tool.
2. Replace the bearing cap. Select-fit the bearing for proper clearance,following procedure given under Fitting Main and Connecting Rod Bearings in Part 21-01.
3. After the bearing has been checked and found to be satisfactory, apply a light coat of SE engine oil to the journal and bearings, then install the bearing cap. Torque the cap bolts to specifications.
4. Repeat the procedure for the remaining bearings that require replacement. If the thrust bearing (No. 3) is being replaced, install the bearing cap with the bolts fingertight. Pry the crankshaft forward against the thrust surface of the upper half of the bearing (Fig. 33). Hold the crankshaft forward and pry the thrust bearing cap to the rear. This will align the thrust surfaces of both halves of the bearing. Retain the forward pressure on the crankshaft. Torque the cap bolts to specifications.
5. If the rear main bearing is replaced, remove the rear main bearing cap. Remove and discard the rear seal and side seals.
6. Clean the rear journal oil seal grooves in the block and cap.
7. Install a new rear oil seal in the rear main bearing cap and block, following the procedures under Crankshaft Rear Oil Seal Replacement.
8. Apply a thin coating of oil-resistant sealer to the rear main bearing cap at the rear of the top mating surface. **Do not apply sealer to the area forward of the side seal groove. Install the rear main bearing cap. Torque the cap bolts to specifications.**
9. Dip the side seals in light engine oil, then immediately install them in the grooves. **Do not use sealer on the side seals. The seals are designed to expand when dipped in oil. Using sealer may retard this expansion.** It may be necessary to tap the seals into place for the last 1/2 inch of travel. Do not cut the seal projecting ends.
10. Check the retainer side seals for leaks by squirting a few drops of oil into the parting lines between the rear main bearing cap and the cylinder block from the outside. Blow compressed air against the seals from the inside of the block. If air bubbles appear in the oil, it indicates possible oil leakage. **This test should not be performed on newly installed seals until sufficient time has been allowed for the seals to expand into the seal grooves.**

11. Disassemble, clean and assemble the oil pump if necessary. Clean the oil pump screen.
12. Prime the pump by pouring oil into the inlet opening and rotating the shaft until the pump is full. Install the oil pump and oil pan. Install the oil level dipstick. Fill the crankcase with the proper amount and viscosity of oil. Install the spark plugs.
13. Operate the engine and check for oil leaks.

CONNECTING ROD BEARINGS

The connecting rod bearings are selective fit. Refer to the procedures under Fitting Main and Connecting Rod Bearings in Part 21-01.

Removal

1. Drain the crankcase and remove the oil level dipstick. Remove the oil pan and oil pump. Remove the spark plugs to allow easy rotation of the crankshaft.
2. Turn the crankshaft until the connecting rod to which new bearings are to be fitted is down.
3. Remove the connecting rod cap. Push the connecting rod up into the cylinder and remove the bearing insert from the rod and cap.
4. Clean the crankshaft journal, rod bearing inserts and cap. Refer to Part 21-01 for the recommended cleaning and inspection procedures.

Installation

1. Install the new bearings in the connecting rod and cap. Pull the connecting rod assembly down firmly on the crankshaft journal. Select-fit the bearing for proper clearance, following procedures given under Fitting Main and Connecting Rod Bearings in Part 21-01.
2. After the bearing clearance has been checked and found to be satisfactory, apply a light coat of SE engine oil to the journal and bearings. Install the connecting rod cap.
3. Repeat the procedure for the remaining connecting rods that require new bearings.
4. Follow steps 11, 12 and 13 under Main Bearing Replacement.

PISTONS AND CONNECTING RODS

Removal

1. Drain the cooling system and the crankcase. Remove the intake manifold, cylinder heads, oil pan and oil pump following the procedures in this Section.
2. Remove any ridge and/or deposits from the upper end of the cylinder bores as follows:

Turn the crankshaft until the piston to be removed is at the bottom of its travel and place a cloth on the piston head to collect the cuttings. Remove any ridge and/or deposits from the upper end of the cylinder bores. Remove the cylinder ridge with a ridge cutter. Follow the instructions furnished by the tool manufacturer. **Never cut into the ring travel area in excess of 1/32 inch when removing ridges.**

3. Make sure all connecting rod caps are marked so that they can be installed in their original locations.
4. Turn the crankshaft until the connecting rod being removed is down.
5. Remove the connecting rod cap.
6. Push the connecting rod and piston assembly out the top of the cylinder with the handle end of a hammer. **Avoid damage to the crankshaft journal or the cylinder wall when removing the piston and rod.**
7. Remove the bearing inserts from the connecting rod and cap.
8. Install the cap on the connecting rod from which it was removed.

Installation

1. If new piston rings are to be installed in used bores, remove the cylinder wall glaze (Part 21-01). Follow the instructions of the tool manufacturer. After performing the cylinder bore repairs, clean the bore(s), following the procedure in Part 21-01.
2. Oil the piston rings, pistons and cylinder walls with light engine oil. Be sure to install the pistons in the same cylinders from which they were removed, or to which they were fitted. The connecting rod and bearing cap are numbered from 1 to 4 in the right bank and from 5 to 8 in the left bank, beginning at the front of the engine. The numbers on the connecting rod and bearing cap must be on the same side when installed in the cylinder bore. If a connecting rod is ever transferred from one block or cylinder to another, new bearings should be fitted and the connecting rod should be numbered to correspond with the new cylinder number.
3. Turn the crankshaft throw to the bottom of its stroke.
4. Make sure the ring gaps are properly spaced around the circumference of the piston (Fig. 34 or 35).
5. Install a piston ring compressor on the piston and push the piston in with a hammer handle until it is slightly below the top of the cylinder (Fig. 36). Be sure to guide the connecting rods to avoid damaging the crankshaft journals. Install the

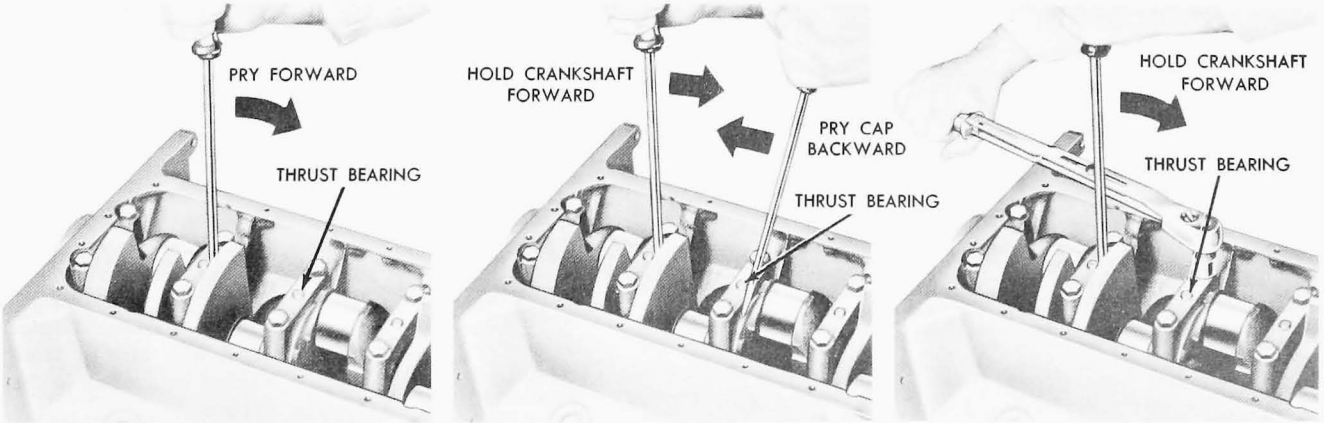

FIG. 33 Aligning Thrust Bearing

piston with the identification in the piston head toward inside of engine V.

6. Check the clearance of each bearing, following the procedure under Connecting Rod Bearing Replacement.
7. After the bearings have been fitted, apply a light coat of SE engine oil to the journals and bearings.
8. Push the piston all the way down until the connecting rod bearing seats on the crankshaft journal. Install the connecting rod cap. Torque the nuts to specifications.
9. After the piston and connecting rod assemblies have been installed, check the side clearance between the connecting rods on each crankshaft journal (Fig. 37).
10. Disassemble, clean and assemble the oil pump. Clean the oil pump inlet tube screen and the oil pan and block gasket surfaces.
11. Prime the oil pump by pouring oil into the inlet opening and rotating the shaft until the pump is full. Install the oil pump and the oil pan.
12. Install the cylinder heads by following the procedures under Cylinder Head Installation.
13. Refer to Intake Manifold Installation and install the intake manifold.
14. Fill and bleed the cooling system. Fill the crankcase with the proper grade and quantity of engine oil.
15. Install the air cleaner, operate the engine and check for oil and coolant leaks. Check and adjust the ignition timing.
16. Connect the distributor vacuum line. When engine temperatures become stabilized, adjust the engine idle speed and fuel mixture.

CRANKSHAFT

The crankshaft and related parts are shown in Fig. 38.

Removal

1. Remove the alternator. Remove the spark plugs to allow easy rotation of the crankshaft.
2. Remove the fuel pump. Remove the oil filter. Remove the water pump by-pass hose. On standard-mount fans, remove the water pump and fan as an assembly.

On high-mount fans, remove the fan and hub assembly, then remove the water pump.

3. On low-mount fans, remove the fan from the crankshaft damper. Remove the crankshaft damper cap screw and washer. Install the puller on the damper (Fig. 19) and remove the damper.
4. Loosen the cylinder front cover bolts, then remove the engine front support bracket and alternator brackets.
5. Remove the cylinder front cover.
6. Remove the crankshaft front oil slinger. Check the timing chain deflection, then remove the timing chain and sprockets by following the applicable steps under Cylinder Front Cover Removal.
7. Invert the engine on the work stand. Remove the flywheel. Remove the engine rear cover plate. Remove the oil pan and gasket. Remove the oil pump.
8. **Make sure all bearing caps (main and connecting rod) are marked so that they can be installed in their original locations.** Remove the connecting rod bearing caps. Turn the crankshaft until the connecting rod from which the cap is being removed is down and remove the cap. Push the connecting rod and piston assembly up into the cylinder.
9. Remove the main bearing caps.
10. Carefully lift the crankshaft out of the block so that the thrust bearing surfaces are not damaged. **Handle the crankshaft with care to avoid possible fracture or damage to the finished surfaces.**

Refer to Part 21-01 for the cleaning and inspection procedures.

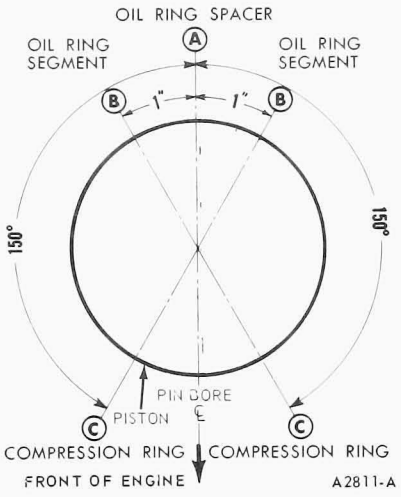

FIG. 34 Piston Ring Gap Spacing — Light Duty

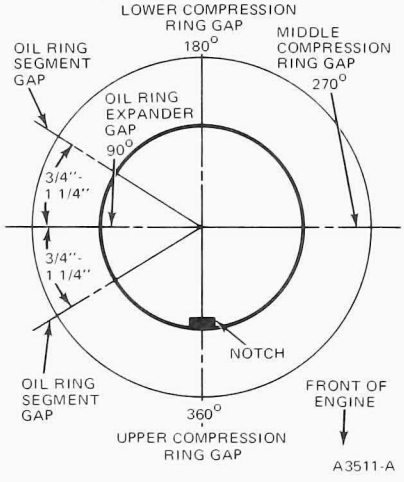

FIG. 35 Piston Ring Gap Spacing — Heavy Duty

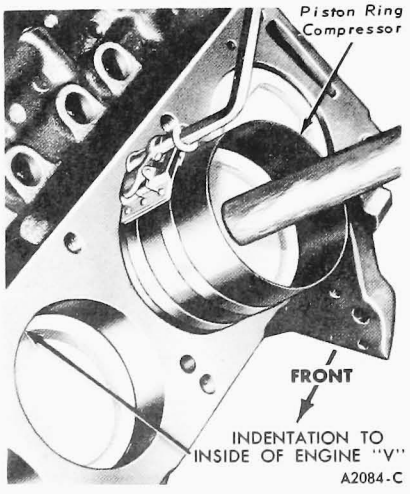

FIG. 36 Piston Installation

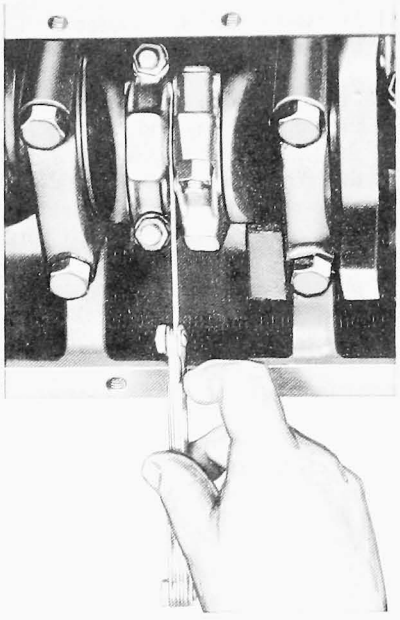

FIG. 37 Checking Connecting Rod Side Clearance

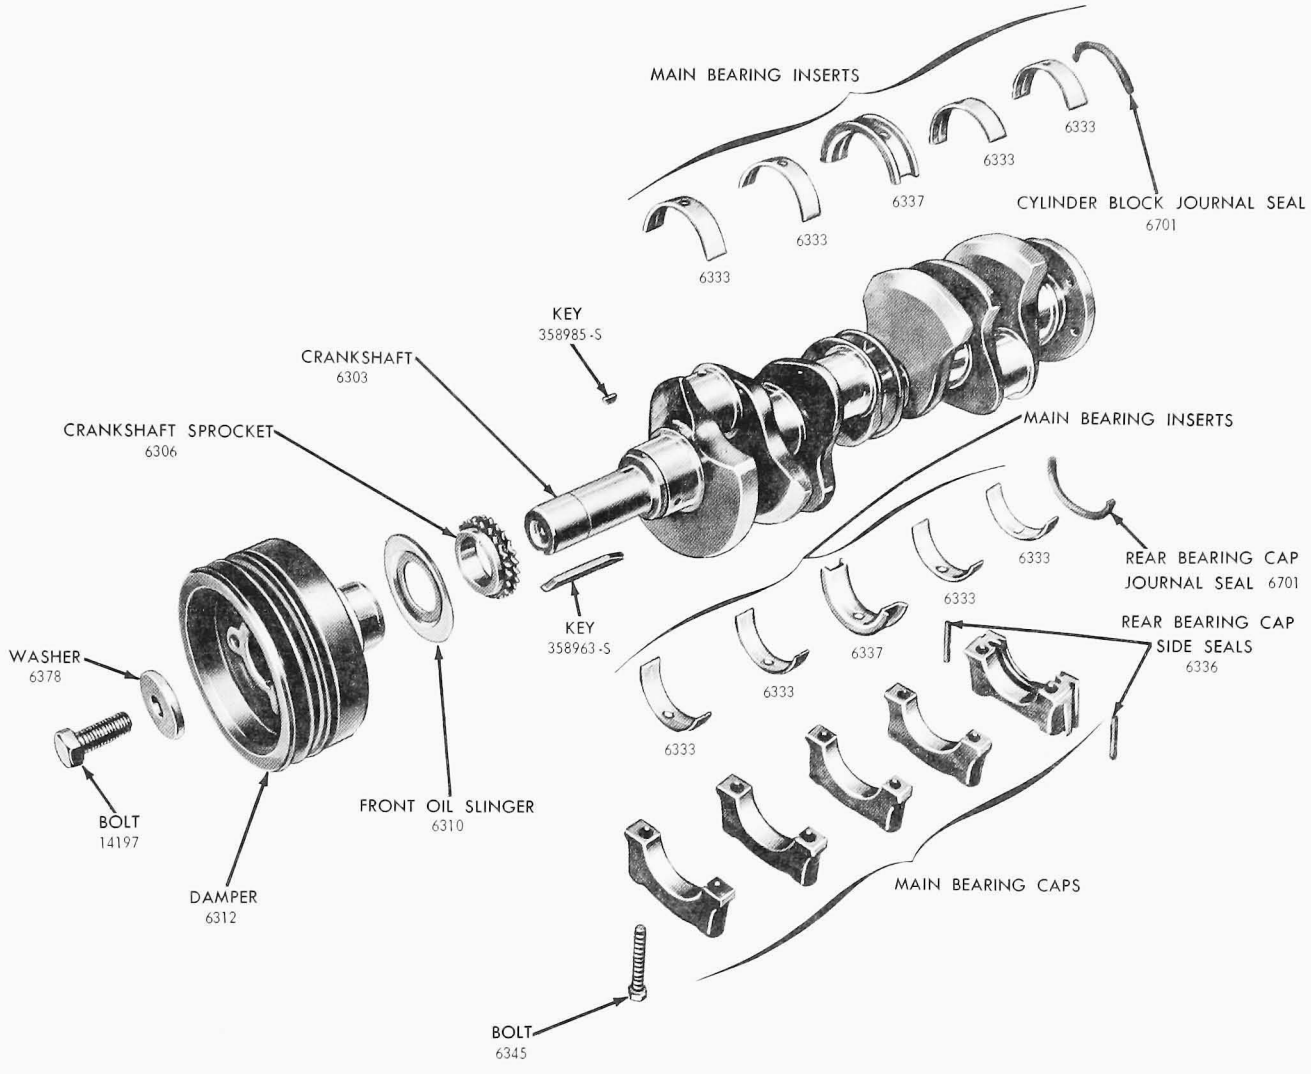

FIG. 38 Crankshaft and Related Parts — Typical

To refinish journals, dress minor imperfections, etc., refer to Part 21-01.

Installation

1. Remove the rear journal oil seal from the block and rear main bearing cap. Remove the rear main bearing cap-to-block side seals.
2. Remove the main bearing inserts from the block and bearing caps.
3. Remove the connecting rod bearing inserts from the connecting rods and caps.
4. If the crankshaft main bearing journals have been refinished to a definite undersize, install the correct undersize bearings. Be sure the bearing inserts and bearing bores are clean. Foreign material under the inserts will distort the bearing and cause a failure.
5. Place the upper main bearing inserts in position in the bores with the tang fitting in the slot provided.

If the oil hole does not line up with the cylinder block oil passage, check the holes with a rod corresponding to the following diameters.

No. 1 Bearing — 7/64 inch
No. 2 Bearing — 9/64 inch
No. 3 Bearing — 9/32 inch
No. 4 Bearing — 5/32 inch
No. 5 Bearing — 9/32 inch

If the rod passes through the bearing and block, sufficient lubrication is assured.

6. Install the lower main bearing inserts in the bearing caps.
7. Dip the seal halves in clean engine oil. Carefully install the upper seal (cylinder block) into its groove with the undercut side of seal toward the FRONT of the engine so that approximately 3/8 inch protrudes above the parting surface.
8. Carefully lower the crankshaft into place. **Be careful not to damage the bearing surfaces.**
9. Select-fit the bearings for proper clearance, following procedures given under Fitting Main and Connecting Rod Bearings in Part 21-01.
10. After the bearings have been fitted, apply a light coat of SE engine oil to the journals and bearings.

Install the lower seal in the rear main bearing cap with the seal lip toward the FRONT of the engine (Fig. 32). Allow the seal to protrude approximately 3/8 inch above the parting surface to mate with the upper seal when the cap is installed.

11. Install all the bearing caps, except the thrust bearing cap (No. 3 bearing). Be sure that the main bearing caps are installed in the original locations. Torque the bearing cap bolts to specifications.

12. Dip the side seals in light engine oil, then immediately install them in the grooves. **Do not use sealer on the side seals. The seals are designed to expand when dipped in oil. Using sealer may retard this expansion.** It may be necessary to tap the seals into place for the last 1/2 inch of travel. Do not cut the seal projecting ends.
13. Check the retainer side seals for leaks by squirting a few drops of oil into the parting lines between the rear main bearing cap and the cylinder block from the outside. Blow compressed air against the seals from the inside of the block. If air bubbles appear in the oil, it indicates possible oil leakage. **This test should not be performed on newly installed seals until sufficient time has been allowed for the seals to expand into the seal grooves.**
14. Install the thrust bearing cap with the bolts fingertight.
15. Pry the crankshaft forward against the thrust surface of the upper half of the bearing (Fig. 33).
16. Hold the crankshaft forward and pry the thrust bearing cap to the rear (Fig. 33). This will align the thrust surfaces of both halves of the bearing.
17. Retain the forward pressure on the crankshaft. Torque the cap bolts to specifications.
18. Check the crankshaft end play by following the procedure in Part 21-01.
19. Install new bearing inserts in the connecting rods and caps. Check the clearance of each bearing, following the procedure under Main Bearing Replacement.
20. After the connecting rod bearings have been fitted, apply a light coat of engine oil to the journals and bearings.
21. Turn the crankshaft throw to the bottom of its stroke. Push the piston all the way down until the rod bearing seats on the crankshaft journal.
22. Install the connecting rod cap. Torque the nuts to specifications.
23. After the piston and connecting rod assemblies have been installed, check the side clearance between the connecting rods on each connecting rod crankshaft journal (Fig. 37).
24. Clean the oil pan, oil pump and oil pump screen. Prime the oil pump by pouring oil into the inlet opening and rotating the shaft until the pump is full. Install the oil pump and oil pan.

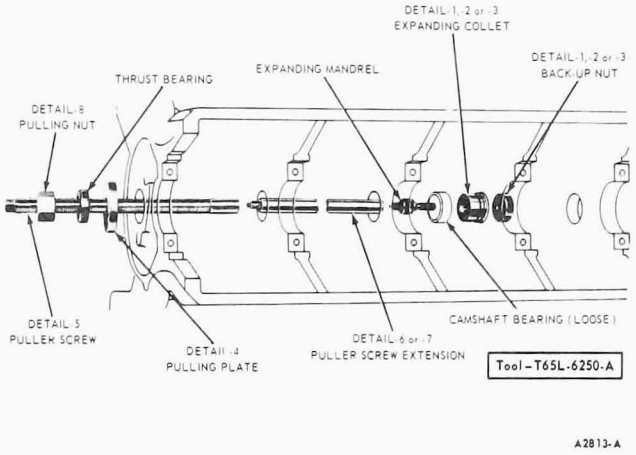

FIG. 39 Replacing Camshaft Bearing

25. Install the engine rear cover plate. Position the flywheel on the crankshaft. Install the attaching bolts. Torque the bolts to specifications.
26. Install the timing chain and sprockets, cylinder front cover and crankshaft damper, following the applicable steps under Cylinder Front Cover Installation.
27. Install the oil filter, fuel pump and carburetor fuel inlet line. Install the alternator. Install the spark plugs.
28. Install the engine in the vehicle.

CAMSHAFT BEARING

Camshaft bearings are available prefinished to size for standard and 0.015-inch undersize journal diameters. The bearings are not interchangeable from one bore to another.

Removal

1. Remove the camshaft, the flywheel and the crankshaft. Push the pistons to the top of the cylinders.
2. Remove the camshaft rear bearing bore plug. Remove the camshaft bearings (Fig. 39).

If the camshaft bearings are being removed with the tool shown in Fig. 39, the following procedure will apply. Select the proper size expanding collet and back-up nut and assemble on the expanding mandrel. With the expanding collet collapsed, install the collet assembly in the camshaft bearing, and tighten the back-up nut on the expanding mandrel. Tighten the pulling nut against bearing. Assemble the puller screw and extension (if necessary) as shown and install on the expanding mandrel. Tighten the pulling nut against the thrust bearing and pulling plate to remove the camshaft bearing. Repeat the procedure for each bearing. To remove the front bearing, install the puller screw from the rear of the cylinder block.

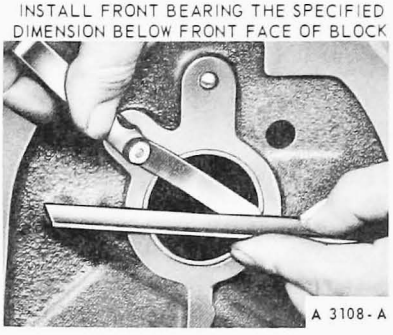

FIG. 40 Measuring Camshaft Front Bearing

Installation

1. Position the new bearings at the bearing bores, and press them in place with the tool shown in Fig. 39. Be sure to center the pulling plate and the puller screw to avoid damage to the bearing. Wrap a cloth around the threads of the puller screw to protect the front bearing or journal. **Failure to use the correct**

expanding collet can cause severe bearing damage. Align the oil holes in the bearings with the oil holes in the cylinder block when the bearings are installed. **Be sure the front bearing is installed the specified distance below the front face of the cylinder block (Fig. 40).**

2. Install the camshaft rear bearing bore plug as detailed in Part 21-01.
3. Install the camshaft, crankshaft, flywheel and related parts. Install the engine in the vehicle.

OIL FILTER

SPIN-ON TYPE

The spin-on type oil filter assembly is shown in Fig. 41.

Removal

1. Place a drip pan under the filter.
2. Unscrew the filter from the adapter fitting. Clean the adapter filter recess.

Installation

1. Coat the gasket on the new filter with oil. Place the filter in position on the adapter. Hand tighten the filter until the gasket contacts the adapter face. Then advance it 1/2 turn.
2. Operate the engine at fast idle and check for leaks. If oil leaks are evident, perform the necessary repairs to correct the leakage. Check the oil level and fill the crankcase if necessary.

CARTRIDGE-TYPE

The replaceable cartridge-type filter is shown in Fig. 42.

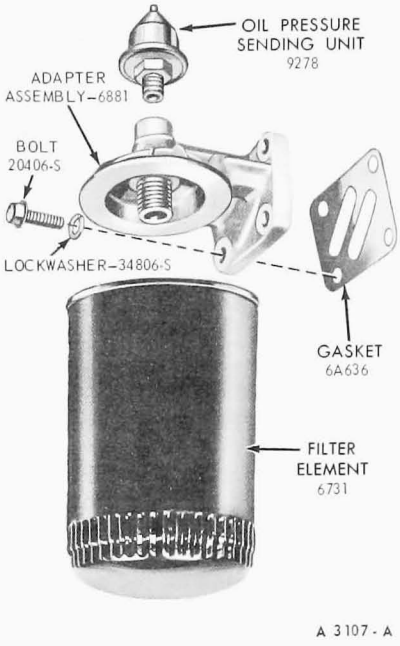

FIG. 41 Typical Oil Filter Assembly — Light Duty

Removal

1. Place a drip pan under the filter. Remove the filter center bolt and remove the filter assembly.
2. Remove the large gasket from filter mounting adapter.
3. Remove the small upper gasket, the replaceable cartridge, and the small lower gasket from the inside of the filter.
4. Remove the center bolt from the filter case, and remove the fiber gasket from the bolt.

Installation

1. Clean the mounting adapter recess, apply grease to a new gasket and position the gasket in the adapter recess.
2. Clean the filter case in solvent and wipe it dry. Position a new fiber gasket on the center bolt and position the bolt in the filter case.
3. Position the new lower gasket, filter cartridge and upper gasket in the filter case.
4. Install the filter assembly and torque the center bolt to specifications.
5. Operate the engine at fast idle and check for leaks. If oil leaks are evident, perform the necessary repairs to correct the leakage. Check the oil level and fill the crankcase if necessary.

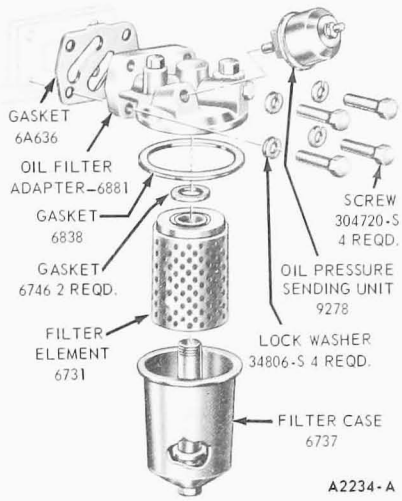

FIG. 42 Cartridge-Type Oil Filter and Adapter Mounting — Heavy Duty

DISASSEMBLY AND ASSEMBLY

When installing nuts or bolts (refer to torque specifications), oil the threads with lightweight engine oil. **Do not oil threads that require oil-resistant or water-resistant sealer.**

ENGINE ASSEMBLY

Disassembly

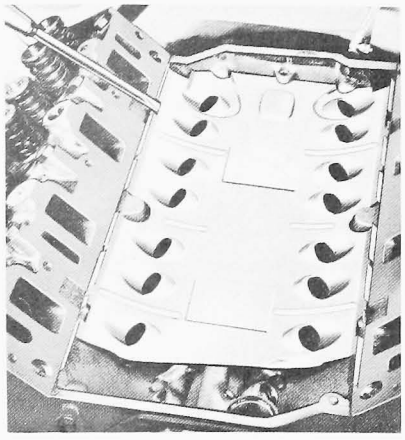
1. Remove the distributor cap and spark plug wire assembly.
2. Disconnect the distributor vacuum line at the distributor. Remove the carburetor fuel inlet line. Remove the fuel pump and discard the gasket.
3. Remove the water pump by-pass hose Remove the crankcase ventilation regulator valve and exhaust tube assembly. Remove the valve rocker arm covers.

Starting at the No. 4 cylinder, loosen the right rocker arm shaft support bolts in sequence, two turns at a time. After the bolts are all loosened remove the valve rocker arm shaft assembly and the oil baffle plate. Starting at the No. 5 cylinder, follow the same procedure on the left valve rocker arm shaft support bolts.

4. Remove the valve push rods in sequence and put them in a rack so that they can be installed in their original bores.
5. Remove the distributor hold-down bolt and clamp and remove the distributor.
6. Remove the intake manifold attaching bolts.
7. Install standard eye bolts with 5/16-18 threads in the left front and right rear rocker arm cover holes and attach the engine lifting sling (Fig. 12).
8. Raise the intake manifold and carefully remove it from the engine. Discard the intake manifold gaskets and seals.
9. Remove the baffle plate from the valve push rod chamber floor by prying up on the baffle with a screw driver (Fig. 43).
10. Using Tool T70P-14151, lift the

valve lifters from the cylinder block and place them in a rack so that they can be installed in their original bores (Fig. 18). The internal parts of each hydraulic valve lifter assembly are matched sets. Do not intermix the parts. Keep the assemblies intact until they are to be cleaned.

11. Remove the exhaust manifolds and the spark plugs.
12. Loosen the cylinder head bolts in sequence: remove them and install the cylinder head holding fixtures.
13. Lift the cylinder heads off the block. **Do not pry between the head and the block.** Discard the cylinder head gaskets.
14. Remove the oil filter. Remove the oil filter adapter assembly and oil pressure sending unit as an assembly. Discard the gasket.
15. Remove the alternator and drive belts.
16. Remove the water pump and fan.
17. Remove the crankshaft damper (Fig. 19) and the crankshaft sleeve (Fig. 20).
18. Loosen the cylinder front cover attaching bolts, then remove the engine front support bracket and alternator brackets.
19. Remove the cylinder front cover. Discard the gasket. Remove the crankshaft front oil slinger.
20. Check the timing chain deflection by following the procedure in Part 21-01.
21. Remove the camshaft sprocket cap screw and the fuel pump eccentric. Remove the crankshaft sprocket key. Remove the sprockets and timing chain as an assembly (Fig. 22).
22. Remove any ridge and/or carbon deposits from the upper end of the cylinder bores. Move the piston to the bottom of its travel and place a cloth on the piston head to collect the cuttings. Remove the cylinder ridge with a ridge cutter. Follow the instructions furnished by the tool manufacturer. **Never cut into the ring travel area in excess of 1/32 inch when removing ridges.** After the ridge has been removed, remove the cutter from the cylinder bore.
23. Remove the flywheel. Remove the engine rear cover plate.
24. Invert the engine. Remove the oil pan. Discard the gasket.
25. Remove the oil pump and inlet tube as an assembly. Remove the oil pump drive shaft. Discard the oil pump gasket.
26. **Make sure all connecting rods and caps are marked so that they can be installed in the original locations. Turn the crankshaft until the connecting rod being removed is down. Remove the rod cap.**
27. Push the connecting rod and piston assembly out of the top of the cylinder with the handle end of a hammer. Avoid damage to the crankpin or the cylinder wall when removing the piston and rod.
28. Remove the bearing inserts from the connecting rods and caps. Install the rod caps on the connecting rods from which they were removed.
29. Remove the main bearing caps.
30. Carefully lift the crankshaft out of the cylinder block so that the thrust bearing surfaces are not damaged. **Handle the crankshaft with care to avoid possible fracture or damage to the finished surfaces.**
31. Remove the rear journal oil seal from the block and rear bearing cap, and remove the cap-to-block side seals.
32. Remove the main bearing inserts from the block and bearing caps. Install the main bearing caps in their original positions.
33. Remove the camshaft thrust plate and spacer. Carefully remove the camshaft by pulling it toward the front of the engine. Use caution to avoid damaging the journals and lobes.
34. Remove the camshaft rear bearing bore plug. Remove the camshaft bearings.



A3160-A

FIG. 43 Removing Baffle Plate

For cleaning and inspection procedures, refer to Part 21-01.

Assembly

Many of the procedures given here are condensed from other sections of this Group. For more detailed steps, refer to the index at the beginning of this part or Part 21-01. These indexes will show the pages on which more detailed instructions can be found.

If the cylinder block is to be replaced, transfer the cylinder head dowels and cylinder block drain plugs to the new cylinder block. Also, omit steps 1 thru 6 below, if a new cylinder block is used.

1. Remove the glaze from the cylinder bores (Part 21-01).
2. Invert the engine on the work stand.
3. Position the new camshaft bearings at the bearing bores, and press them in place. Align the oil holes in the cylinder block when the bearings are installed. **Be sure the camshaft front bearing is installed 0.005-0.020 inch below the front face of the cylinder block (Fig. 40).**
4. Clean out the camshaft rear bearing bore plug recess thoroughly.
5. Coat the flange of a new plug with oil-resistant sealer and install it with the flange facing inward.
6. Drive the plug in until it is flush or slightly below the casting surface.
7. Oil the crankshaft journals and apply Lubriplate to all lobes, then carefully install the camshaft and thrust plate following the procedure under Camshaft Installation.
8. Clean the rear journal oil seal groove and the mating surfaces of the block and rear main bearing cap. Dip the seal halves in clean engine oil. Carefully install the upper seal (cylinder block) into its groove with the undercut side of seal toward the FRONT of the engine (Fig. 32), and approximately 3/8 inch protrudes above the parting surface.
9. If the crankshaft main bearing journals have been refinished to a definite undersize, install the correct undersize bearings. Be sure the bearing inserts and bearing bores are clean. Foreign material under the inserts will distort the bearing and cause a failure.

Place the upper main bearing inserts in position in the bore with the tang fitting in the slot provided.

10. Install the lower main bearing inserts in the bearing caps.
11. Carefully lower the crankshaft into place. **Be careful not to damage the bearing surfaces.**
12. Check the clearance of each main bearing, following the procedure under Main Bearing Replacement.
13. After the bearings have been fitted, apply a light coat of engine oil to the journals and bearings.
14. Be sure that the oil seal grooves in the rear main bearing cap are clean. Install the lower seal in the rear main bearing cap with the seal lip toward the FRONT of the engine (Fig. 32). Allow the seal to protrude approximately 3/8 inch above the

parting surface to mate with the upper seal when the cap is installed. Apply a thin coating of oil-resistant sealer to the rear of the top mating surface. **Do not apply sealer to the area forward of the side seal groove. Install the rear main bearing cap and the remainder of the caps, except the thrust bearing cap (No. 3 bearing).** Be sure that the main bearing caps are installed in their original locations. **Torque the bearing cap bolts to specifications.**

15. Dip the side seals in light SE engine oil, then immediately install them in the grooves. **Do not use sealer on the side seals. The seals are designed to expand when dipped in oil. Using sealer may retard this expansion.** It may be necessary to tap the seals into place for the last 1/2 inch of travel. Do not cut the seal projecting ends.

Check the retainer side seals for leaks by squirting a few drops of oil into the parting lines between the rear main bearing cap and the cylinder block from the outside. Blow compressed air against the seals from the inside of the block. If air bubbles appear in the oil, it indicates possible oil leakage. **This test should not be performed on newly installed seals until sufficient time has been allowed for the seals to expand into the seal grooves.**

16. Install the thrust bearing cap and check crankshaft end play by following the applicable steps under Crankshaft Installation.
17. Turn the engine on the work stand so that the front end is up.
18. Install the pistons and connecting rods, following the recommended procedure under Piston and Connecting Rod Installation.
19. Position the sprockets and timing chain on the camshaft and crankshaft (Fig. 22). Be sure the timing marks on the sprockets are positioned as shown in Fig. 21.
20. Lubricate the timing chain and sprockets with engine oil.
21. Install the fuel pump eccentric (Fig. 23) and the camshaft sprocket cap screw. Torque the sprocket cap screw to specifications. Install the crankshaft front oil slinger.
22. Clean the cylinder front cover and the cylinder block gasket surfaces. Install a new crankshaft front oil seal (Fig. 26).
23. Coat the gasket surface of the block and cylinder front cover and the cover bolt threads with oil-resistant sealer. Position a new gasket on the block.
24. Install the alignment pilot tool on the cylinder front cover so that the keyway in the pilot aligns with the key in the crankshaft. Position the cover and pilot over the end of the crankshaft and against the block (Fig. 24).
25. Position the engine front support bracket and alternator brackets on the cylinder front cover. Install the cylinder front cover bolts fingertight. Align the oil pan gasket surfaces on the cylinder block and front cover. While pushing in on the pilot tool, torque the cover bolts to specifications. Remove the pilot.
26. Lubricate the crankshaft with a white lead and oil mixture and lubricate the oil seal rubbing surface with grease.
27. Line up the damper keyway with the key on the crankshaft, and install the damper on the crankshaft (Fig. 25). Install the damper cap screw and washer, and torque the screw to specifications.
28. Clean the water pump gasket surfaces and apply sealer. Position new gaskets on the pump and install the water pump and fan as an assembly.
29. On a high-mount fan, install the fan and hub after the water pump is installed.
30. On a low-mount fan, install it on the crankshaft damper.
31. Using a new gasket, install the fuel pump. Install the alternator and drive belts.
32. Turn the engine on the work stand so that the top of the engine is up.
33. Clean the cylinder head and block gasket surfaces. Guided by the word FRONT on the gasket install the head gasket over the cylinder head dowels.
34. Place the cylinder head on the engine, and remove the holding fixtures. Oil the head bolt threads and install the bolts.
35. The cylinder head bolt tightening procedure is performed in three progressive steps. Torque the bolts in sequence (Fig. 15) to specifications. When the cylinder head bolts have been tightened by this procedure, it is not necessary to retorque the bolts after extended operation.
36. Coat the mating surfaces of the exhaust manifolds with a light film of graphite grease.
37. Position a new gasket over the muffler inlet pipe studs of the exhaust manifolds.
38. Position the exhaust manifolds on the cylinder heads and install the retaining bolts and tab washers. Torque the retaining bolts to specifications, working from the center to the end. Lock the bolts by bending one tab of the washer over a flat on the bolt.
39. Install the spark plugs.
40. Use the hydraulic valve lifter leakdown tester (Part 21-01) to fill the lifters with test fluid. Coat the outside of each valve lifter with engine oil to provide initial lubrication. Place each lifter in the bore from which it was removed.
41. Install the baffle plate in the valve push rod chamber. Position one side of the baffle plate and press the other side into place.
42. Clean the mating surfaces of the intake manifold, cylinder heads and cylinder block.
43. Coat the cylinder block seal surfaces with quick setting contact adhesive.
44. Position new seals on the cylinder block and new gaskets on the cylinder heads. Position the gasket slots in the end tabs over the ribs on the seals. Be sure the holes in the gaskets are aligned with the holes in the cylinder heads. The correct installation of the gaskets and seals is shown in Fig. 13. Follow the procedure as described under Intake Manifold Installation.
45. Install the eye bolts in the intake manifold and attach the engine lifting sling and carefully lower the intake manifold on the engine (Fig. 12).
46. Position the intake manifold by temporarily inserting the distributor in place. **After the intake manifold is in place, run a finger around the seal area to make sure the seals are in place. If the seals are not in place, remove the intake manifold and position the seals.**
47. Install the water pump by-pass hose on the intake manifold and on the water pump.
48. Be sure the holes in the manifold gaskets and manifold are in alignment. Install the manifold attaching bolts and torque them to specifications, in sequence as shown in Fig. 14.
49. Remove the distributor and the engine lifting sling and eye bolts.
50. Refer to Valve Rocker Arm Shaft Assembly Installation and install the valve rocker arm shaft assemblies.
51. Rotate the crankshaft damper until the No. 1 piston is on TDC at the end of the compression stroke, then position the distributor in the block with the rotor at the No. 1 firing position and the points open. Install the hold-down clamp.

52. Install the distributor cap. Install the valve rocker arm covers.
53. Install the crankcase ventilation regulator valve in the valve rocker arm cover or oil fill cap and connect the hose.
54. Connect the spark plug wires. Connect the carburetor fuel inlet line and the distributor vacuum line at the carburetor.
55. Invert the engine on the work stand. Position the oil pump drive shaft into the distributor socket. With the shaft firmly seated in the distributor socket, the stop on the shaft should touch the roof of the crankcase. Remove the shaft and position the stop as necessary.
56. With the stop properly positioned, insert the oil pump drive shaft into the oil pump.
57. Prime the oil pump by filling the inlet port with the engine oil. Rotate the pump shaft to distribute the oil within the pump body.
58. Position a new gasket on the pump housing and install the pump and shaft as an assembly. **Do not attempt to force the pump into position if it will not seal readily. The drive shaft hex may be misaligned with the distributor shaft. To align, rotate the intermediate shaft into a new position.**
59. Position a new gasket on the oil pan and place the oil pan assembly on the block. Install the attaching screws and torque them from the center outward to specifications.
60. Install the engine rear cover plate. Position the flywheel on the crankshaft and install the attaching bolts. Torque the bolts alternately to specifications.
61. Clean the oil filter adapter gasket surfaces. Apply sealer to a new adapter gasket, and install the adapter assembly and gasket.
62. Clean the adapter filter recess. Place the filter in position and install it on the adapter. Tighten the center bolt to specification. On 330 MD engines install the spin-on filter by hand tightening until the gasket contacts the adapter face. Then advance it 1/2 turn.
63. Install the engine in the vehicle. Install the air cleaner and operate the engine and check for oil and coolant leaks. Check the ignition timing. Connect the distributor vacuum line to the distributor. Adjust the engine idle speed and idle fuel mixture.

VALVE ROCKER ARM

The valve rocker arm shaft assembly is shown in Fig. 44.

Disassembly

1. Remove the cotter pins from each end of the valve rocker arm shaft. Remove the flat washer and spring washer from each end of the shaft.
2. Slide the rocker arms, spring and supports off the shaft. Be sure to identify all the parts.
3. If it is necessary to remove the plugs from each end of the shaft, drill or pierce one plug. Insert a steel rod through the drilled plug and knock out the plug on the opposite end. Working from the open end, knock out the remaining plug.

Refer to Part 21-01 for the cleaning, inspection and repair procedures.

Assembly

1. Oil all the moving parts with engine oil. Apply Lubriplate to the pad of the valve rocker arms.
2. If the plugs were removed from the ends of the shaft, use a blunt tool or large diameter pin punch and install a plug, cup side out, in each end of the rocker arm shaft.
3. Install the rocker arms, supports, and springs in the order shown in Fig. 44. **Be sure the oil holes in the shaft are facing downward.** When properly assembled, the identification notch (Fig. 11) on the end of the shaft must be downward and toward the front on the right bank and toward the rear on the left bank. Complete the assembly by installing the remaining flat washers and the spring washer, then install the cotter pin.

CYLINDER HEADS

Disassembly

1. Clean the carbon out of the cylinder head combustion chambers before removing the valves.
2. Compress the valve spring (Fig. 45). Remove the spring retainer locks and release the spring.
3. Remove the sleeve, spring retainer, spring, stem oil seal and valve. Discard the valve stem seals. Identify all valve parts.

Refer to Part 21-01 for the cleaning and inspection procedures.

Cylinder head repair procedures and checks such as valve and valve seat refacing, cylinder head flatness checks, etc., are covered in Part 21-01.

Assembly

1. Oil each stem and install each valve in the port from which it was removed or to which it was fitted. Install a new oil seal on the valve stem (Figs. 46 and 47).

Do not install the O-ring type seal

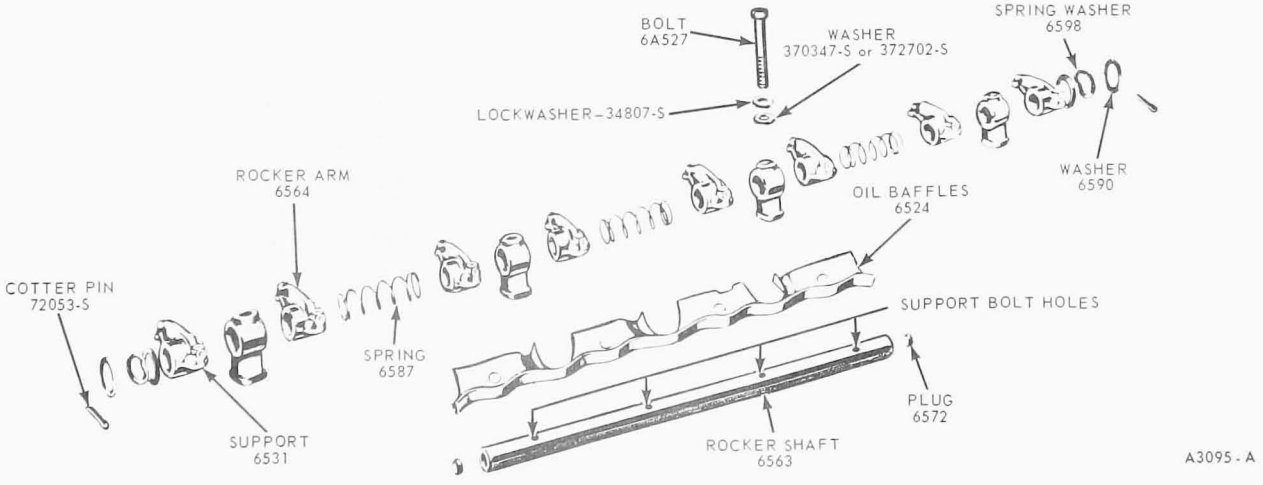


FIG. 44 Valve Rocker Arm Shaft Assembly

on the exhaust valve (Fig. 47) at this time.

2. Install the valve spring over the valve.

LD engines use a damper spring in conjunction with the valve spring (Fig. 47). Use a positive rotating spring retainer on the exhaust valves of all MD and HD engines (Fig. 46).

3. Compress the spring (Fig. 45). If working on a MD or HD engine, apply SE engine oil to the O-ring type seal, then install it on the exhaust valve. Install the retainer locks.
4. Measure the assembled height of the valve spring from the surface of the cylinder head spring pad to the underside of the spring retainer with dividers (Fig. 48). Check the dividers against a scale. If the assembled height is greater than specifications, install the necessary 0.030-inch thick spacer(s) between the cylinder head spring pad and the valve spring to bring the assembled height to the recommended height.

Do not install spacers unless necessary. Use of spacers in excess of recommendations will result in overstressing the vavle springs and overloading the camshaft lobes which could lead to spring breakage and worn camshaft lobes.

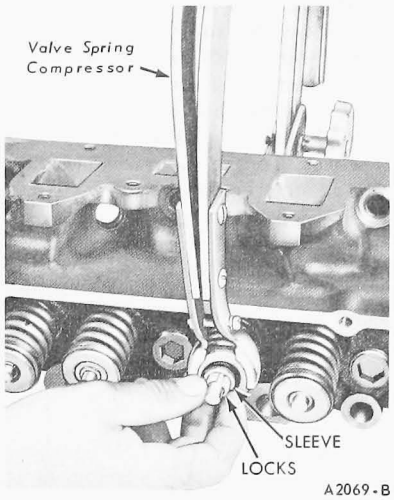

FIG. 45 Compressing Valve Spring — On Bench

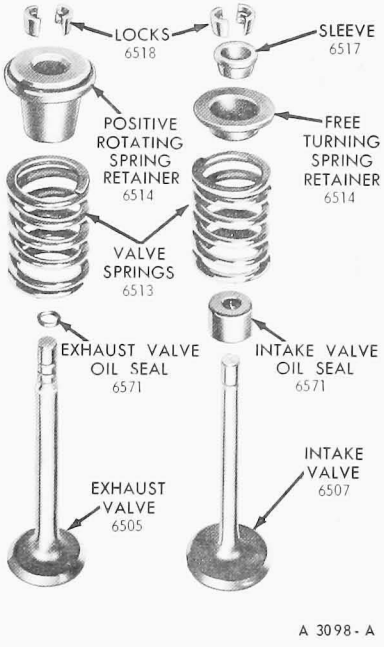

FIG. 46 Valve Assemblies — MD and HD Engines

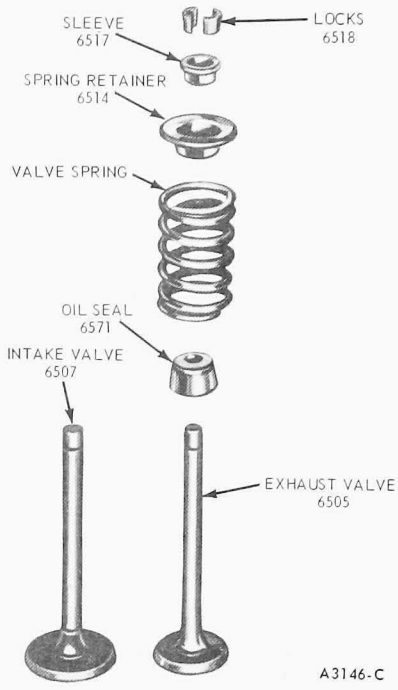

FIG. 47 Valve Assemblies — LD Engines

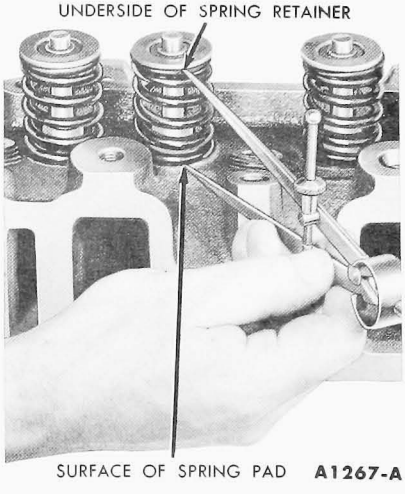

FIG. 48 Checking Valve Spring Assembled Height

VALVE LIFTER

A typical hydraulic valve lifter assembly is shown in Fig. 49.

Each valve lifter is a matched assembly. If the parts of one lifter are intermixed with those of another improper valve operation may result. Disassemble and assemble each lifter separately. Keep the lifter assemblies in proper sequence so that they can be installed in their original bores.

Disassembly

1. Grasp the lock ring with needle nose pliers to release it from the groove. It may be necessary to depress the plunger to fully release the lock ring.
2. Remove the push rod cup, plunger (Fig. 50), and spring.
3. Invert the plunger assembly and remove the disc valve retainer by carefully prying up on it with a screwdriver. Remove the disc valve and spring.

Refer to Part 21-01 for the cleaning, inspection and test procedures.

Assembly

1. Place the plunger upside down on a clean work bench.
2. Place the disc valve in position over the oil hole on the bottom of the plunger. Set the disc valve spring on top of the disc.
3. Position the disc valve retainer over the disc and spring, and push the retainer down into place on the plunger.
4. Place the plunger spring, and then the plunger (open end up) into the lifter body.
5. Place the push rod seat in the plunger.
6. Push the plunger and push rod cup into the body and install the lock ring (Fig. 51). Release the plunger, then depress it again to fully seat the lock ring.

OIL PUMP

A typical oil pump assembly is shown in Fig. 52.

Disassembly

1. Remove the oil inlet tube from the oil pump and remove the gasket.
2. Remove the cover attaching bolts then remove the cover. Remove the inner rotor and shaft assembly and the outer race.
3. Drill a small hole in the relief valve plug, then insert a self-threading sheet metal screw of the proper

diameter into the oil pressure relief valve chamber plug and pull the plug out of the chamber. Remove the spring and plunger.

Refer to Part 21-01 for the cleaning and inspection procedures.

Assembly

1. Oil all parts thoroughly.
2. Install the oil pressure relief valve plunger, spring and a new plug.
3. Install the outer race, and the inner rotor and shaft assembly. **Be sure the dimple (identification mark) on the outer race is facing outward and on the same side as identification mark on the rotor. The inner rotor and shaft and the outer race are serviced as an assembly. One part should not be replaced without replacing the other.** Install the cover. Torque the cover attaching bolts to specifications.
4. Position a new gasket and the oil inlet tube on the oil pump and install the attaching bolts.

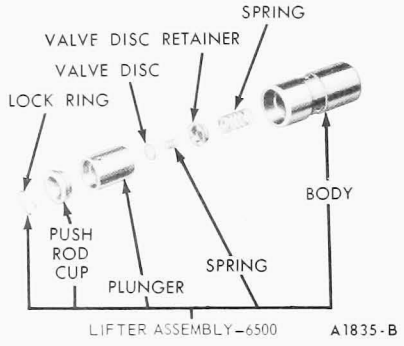

FIG. 49 Typical Hydraulic Valve Lifter Assembly

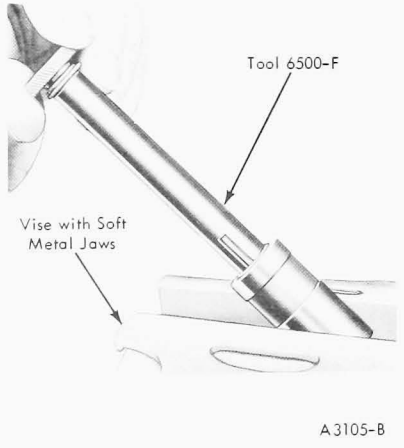

FIG. 50 Removing Lifter Plunger

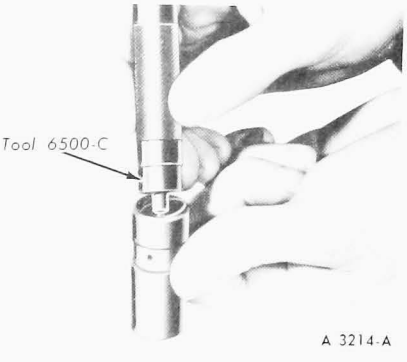

FIG. 51 Installing Valve Lifter Lock Ring

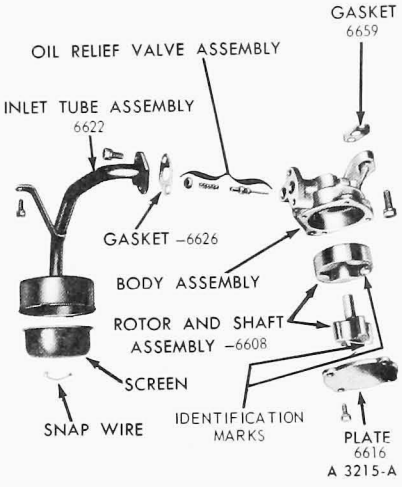

FIG. 52 Oil Pump Assembly — Typical

PISTON AND CONNECTING ROD ASSEMBLY

The piston, connecting rod and related parts are shown in Fig. 53.

Disassembly

1. Mark the pistons and pins to assure assembly with the same rod and installation in the same cylinder from which they were removed.
2. Remove the piston rings. Remove the piston pin retainers. Drive the pin out of the piston and connecting rod (Fig. 54). Discard the retainers.

Refer to Part 21-01 for the cleaning, inspection and repair procedures.

Assembly

1. Lubricate all parts with light engine oil. Position the connecting rod in the piston and push the pin into place. Assemble the piston and connecting rod as shown in Fig. 55.
2. Insert new piston pin retainers into the piston. Follow the instructions contained on the piston ring package and install the piston rings. Be sure the piston ring gaps are properly spaced (Figs. 34 or 35).
3. Check the ring side clearance of the compression rings with a feeler gauge (refer to Part 21-01).
4. Be sure the bearing inserts and the bearing bore in the connecting rod and cap are clean. Foreign material

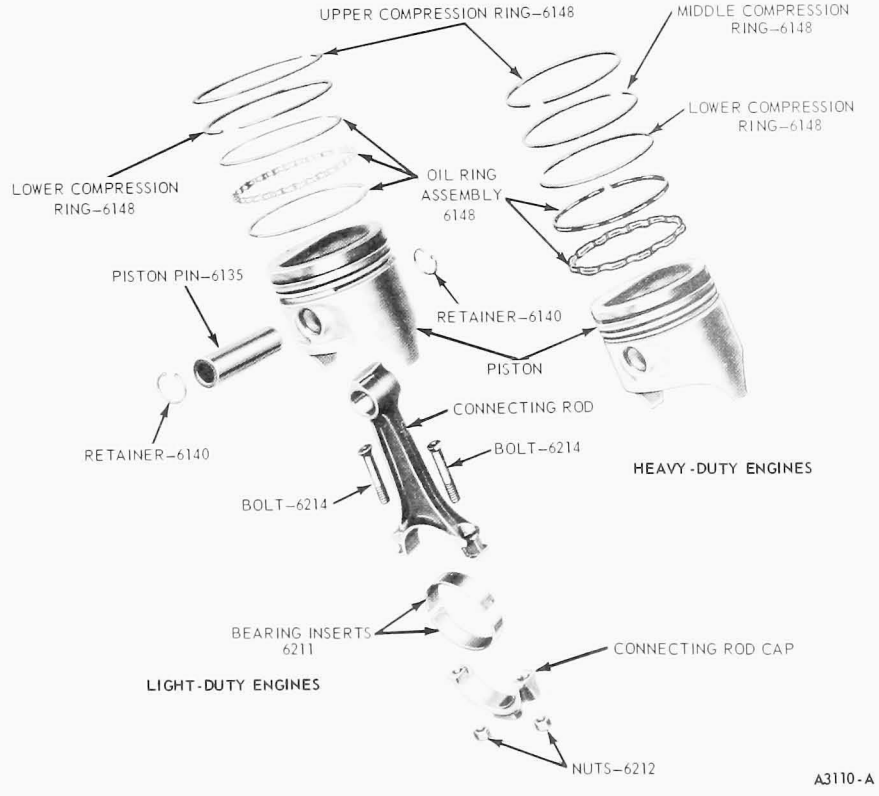

FIG. 53 Piston, Connecting Rod and Related Parts

under the inserts will distort the bearing and cause a failure. Install the bearing inserts in the connecting rod and cap with the tangs fitting in the slots provided.

CYLINDER ASSEMBLY

Disassembly

Follow steps 1 thru 11, 13 thru 20, and 24 thru 26 under Engine Disassembly. Remove the cylinder head dowels from the cylinder block. Remove the cylinder block drain plugs and remove the cylinder assembly from the workstand.

Clean the gasket and seal surfaces of all parts and assemblies (refer to Part 21-01).

Assembly

Install the replacement cylinder block assembly on a workstand. Install the cylinder block drain plugs and cylinder head dowels. Transfer all parts removed from the old cylinder assembly to the new cylinder assembly and check all assembly clearances and correct as required, following the procedures in steps 22 thru 39 and 41 thru 63 under Engine Assembly.

CYLINDER BLOCK

Before replacing a cylinder block, determine if it is repairable, and make the necessary repairs by following the procedures in Part 21-01.

Disassembly

Follow steps 1 thru 34 under Engine Disassembly. Remove the cylinder head dowels and cylinder block drain plugs. Remove the intake and exhaust manifolds and cylinder head as an assembly. Remove the cylinder block from the workstand.

Clean the gasket and seal surfaces of all parts and assemblies (Part 21-01).

Assembly

Install the replacement cylinder block on a workstand. Install the cylinder block drain plugs and cylinder head dowels. Transfer all parts removed from the old cylinder block to the new cylinder block and check all assembly clearances and correct as required, following steps 7 thru 62 under Engine Assembly. Install the manifolds and cylinder head as an assembly.

DESCRIPTION

ENGINE

The differences between the engine models and the vehicle model applications are listed in Fig. 1. The 401, 477 and 534 SD (Super Duty) V-8 engines (Figs. 2 and 3) have the same basic design.

The engines are equipped with a positive crankcase ventilation system.

On a closed-type crankcase ventilation system, the oil filler caps are sealed and connected to the air cleaner (L-LT-C-and CT-Series) (Fig. 4). Thus, the crankcase receives air from the air cleaner. If the system becomes restricted, a backflow condition will occur, thereby venting the crankcase gases into the air cleaner.

Rating Plate Identification	Engines	Piston Displacement (Cu. In.)	Bore (Inches)	Stroke (Inches)	Compression Ratio	Carburetor	Governor	Distributor	Vehicle Model Application
H	401 SD V-8	401	4.125	3.75	7.5:1	4-V	Mechanical-Centrifugal	'Centrifugal and Vacuum	L-900,LN-900,C-900 LT-900,LNT-900,CT-900, LTS-900
K	477 SD V-8	477	4.500	3.75	7.5:1	4-V	Mechanical-Centrifugal	Centrifugal and Vacuum	L-900,LN-900,C-900 LT-900,LNT-900,CT-900, LTS-900
L	534 SD V-8	534	4.500	4.20	7.5:1	4-V	Mechanical-Centrifugal	Centrifugal and Vacuum	L-900,LN-900,C-900 LT-900,LNT-900,CT-900, LTS-900

ADJUSTMENTS

VALVE CLEARANCE

It is important that the valve lash be held to the correct specifications. If the lash is set too close, the valve will open too early and close too late, resulting in rough engine idle. Burning and warping of the valves will occur also because the valves cannot make firm contact with the seats long enough to cool properly. If the lash is excessive, it will cause the valve to open too late and close too early, causing valve bounce. In addition, damage to the camshaft lobe is likely because the tappet foot will not follow the pattern of the camshaft lobe, causing a shock contact between these two parts.

PRELIMINARY (COLD) ADJUSTMENT

If some component of the valve train has been replaced; i.e., rocker arm, push rod, camshaft, etc., it will be necessary to make a preliminary (cold) valve lash adjustment before starting the engine. If the valve lash adjustment is made for an engine tune-up, follow the final (hot) adjustment procedure.

On V-8 engines, the cylinders are numbered from front to rear: right bank, 1-2-3-4-; left bank, 5-6-7-8. On the 401, 477 and 534 V-8 engines, the valves are arranged from front to rear on both banks, E-I-E-I-I-E-I-E.

1. Install an auxiliary starter switch. **Crank the engine with the ignition switch OFF.**
2. On the 401-477 and 534 V-8 engines, make three chalk marks on the crankshaft damper (Fig. 5). Space the marks approximately 90 degrees apart so that with the timing marks the damper is divided into four equal parts (90 degrees represents 1/4 of the distance around the damper circumference). Set the intake and exhaust valve lash (Fig. 6) to specifications with a step-type feeler gauge (go and no go).

Rotate the crankshaft until No. 1 piston is near TDC at the end of the compression stroke. Loosen the lock nut and turn the adjusting screw to adjust the following valves, and tighten the lock nut to specifications:

No. 1 Exhaust No. 1 Intake
No. 4 Exhaust No. 2 Intake
No. 5 Exhaust No. 7 Intake

Rotate the crankshaft 180 degrees or 1/2 turn in the direction shown in Fig. 5 (this puts No. 4 piston on TDC). Adjust the following valves:

No. 6 Exhaust No. 4 Intake
No. 8 Exhaust No. 5 Intake

Rotate the crankshaft another 3/4 turn in the same direction (this puts No. 3 piston on TDC). Adjust the following valves:

No. 2 Exhaust No. 3 Intake
No. 3 Exhaust No. 6 Intake
No. 7 Exhaust No. 8 Intake

FINAL (HOT) ADJUSTMENT

1. Be sure the engine is at normal operating temperature before attempting to set the valve lash.
2. With the engine idling, set the valve lash (Fig. 6) using a step-type feeler gauge only (go and no go). The final (hot) intake and exhaust valve lash settings are listed in the specifications.

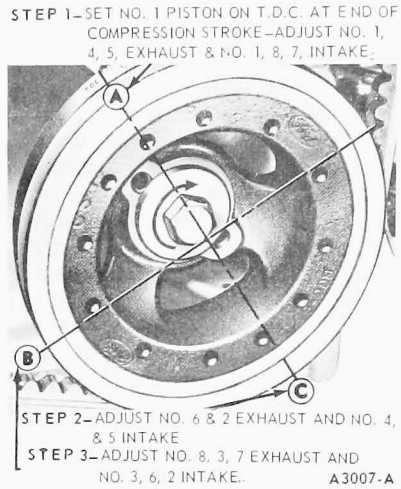

FIG. 5 Preliminary (Cold) Valve Clearance Adjustment

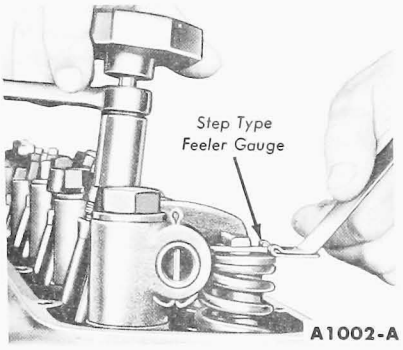

FIG. 6 Final (Hot) Valve Clearance Adjustment

REMOVAL AND INSTALLATION

When installing nuts or bolts that must be torqued (refer to the end of this Part for torque specifications), oil the threads with light weight engine oil. **Do not oil threads that require oil-resistant or water-resistant sealer.** Lubricate all bearing and/or mating surfaces with engine oil.

ENGINE

The engine removal and installation procedures are for the engine only without the transmission attached.

L, LT AND LTS-SERIES

Removal

1. Support the hood and fenders in a vertical position.
2. Drain the cooling system and the crankcase.
3. Disconnect the battery ground strap. Disconnect the crankcase ventilation system hose. Remove the carburetor air cleaner.
4. Remove the fan, radiator shutter, and the fan shroud.

Disconnect the vacuum assist brake line at the intake manifold.

On a vehicle with power steering, disconnect the power steering return line and the pump pressure line at the bracket on the frame left side member. Drain the oil into a suitable container. Disconnect the power steering return line at the pump steering return line at the pump reservoir and the pressure line at the pump housing.

On a vehicle with an air compressor, loosen the outlet line at the air compressor and allow the air to escape,

then disconnect the line. Disconnect the air compressor governor line at the air compressor.

5. Disconnect the heater hose at the water pump and at the intake manifold.
6. Disconnect the wires at the coil, and the oil pressure and temperature sending unit wires at the sending units. Remove the wiring harness from the clip at the coil and on the intake manifold, then position the wiring harness on the dash panel.
7. Disconnect the choke cable at the carburetor and position it on the dash panel.
8. Disconnect the oil pressure safety switch wires at the switch.
9. Disconnect the fuel filter inlet line at the flexible hose and remove the retaining clamp at the intake manifold.
10. Disconnect the tachometer drive cable at the governor.
11. Remove the accelerator retracting spring, and remove the accelerator linkage retaining clip at the carburetor.
12. Remove the hand throttle cable from the carburetor and position it on the dash panel. Disconnect the engine ground strap at the dash panel.
13. Disconnect the wiring harness at the alternator.
14. Remove the oil filter.
15. Disconnect the right and left muffler inlet pipes at the exhaust manifolds.
16. Place a jack under the front bumper at the right side and raise the right front of the vehicle. Remove the starter shield and starter, then lower the vehicle and remove the jack.
17. Install the engine lifting eye bolts and sling (Fig. 7).
18. Remove the engine front support to frame attaching bolts, nuts, and washers. Remove the flywheel housing dust cover.
19. Position a jack under the transmission and remove the flywheel housing to engine attaching bolts.
20. Remove the engine from the chassis and install it on a work stand (Fig. 8).

Installation

1. Install guide pins in the two flywheel housing lower bolt holes in the engine.
2. Place new muffler inlet pipe gaskets over the exhaust manifold studs.
3. Attach the engine lifting eye bolts and sling (Fig. 7) and remove the engine from the work stand.
4. Carefully lower the engine into the chassis. Make sure the exhaust manifolds are properly aligned with the muffler inlet pipes and that the guide pins in the cylinder block engage the holes in the flywheel housing.
5. Install two flywheel housing bolts and remove the guide pins. Install the remaining bolts, then tighten all the bolts to speicifcations.
6. Remove the jack from transmission. Install the flywheel housing dust cover.
7. Install the engine front support bolts, washers, and nuts; then tighten them to specifications. Install the oil filter. Connect the muffler inlet pipes.
8. Place a jack under the front bumper at the right side and raise the right front of the vehicle. Install the starter and starter shield; then lower the vehicle and remove the jack.
9. Remove the engine lifting eyes and sling. Connect the ignition wires.

Connect the vacuum assist brake line at the intake manifold.

On a vehicle with an air compressor, connect the governor line and the outlet at the air compressor.

On a vehicle with power steering, connect the power steering return line to the pump reservoir and the pressure line at the pump housing. Connect the return line and pressure line to the bracket on the frame left side member.

10. Connect the hand throttle cable, accelerator linkage and retaining clip, and the accelerator return spring.
11. Connect the fuel inlet line and connect the retaining clamp to the intake manifold. Position the wiring harness in the retaining clip at the left rear corner of the intake manifold.
12. Connect the ignition coil wires, the alternator wires, the choke control cable, the tachometer drive cable, the oil pressure and engine temperature sending unit wires, and the oil pressure safety switch wires.
13. Connect the heater return hose to the water pump and the heater inlet hose at the engine.
14. Position the fan shroud in the engine compartment; then install the radiator and radiator shutter. Install the fan blade assembly, then install the fan shroud. Connect the radiator inlet and outlet hoses.
15. Connect the battery ground strap.
16. Fill and bleed the cooling system. Fill the crankcase with the proper grade and quantity of engine oil.

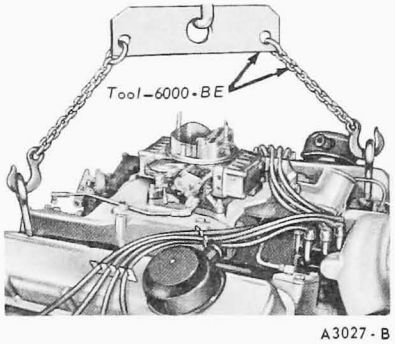
On a vehicle with power steering, fill the power steering pump following the recommended procedure.

17. Operate the engine at fast idle and check all gaskets and hose connections for leaks.
18. Install the air cleaner and connect the closed crankcase ventilation system hose. Secure the hood and fenders in the locked position.

C-AND CT-SERIES

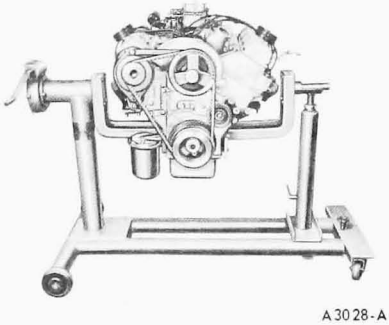
Removal

1. Release the cab lock and tilt the cab forward.
2. Drain the cooling system and the crankcase.
3. Disconnect the battery ground cable at the battery. Disconnect the crankcase ventilation hose, and remove the carburetor air cleaner. Remove the oil level dipstick.
4. Disconnect the oil filler hose at the valve rocker arm cover. Disconnect the radiator supply tank tube at the front thermostat housing. Disconnect the cab latch anti-rattle springs, then remove the bracket and tank assembly.
5. Disconnect the resistor, tachometer and distributor wires from the coil. Disconnect the oil pressure and engine temperature wires at the



A3027-B

FIG. 7 Engine Lifting Sling—Typical



A3028-A

FIG. 8 Engine Mounted on Work Stand—Typical

sending units. Disconnect the choke control cable at the carburetor.
6. Disconnect the oil pressure safety switch wires at the switch. Disconnect the heater hoses at the engine and remove the hose retaining bracket from the intake manifold. Remove the heater return hose adapter from the water pump.
7. Disconnect the radiator outlet hose at the water pump and slide the hose downward.
8. Disconnect the wires at the alternator. Loosen the alternator mounting bolts and the adjusting arm bolts, then remove the two drive belts. Remove the oil filter.
9. Remove the starter shield and starter.
10. Disconnect the hand throttle control cable and the accelerator cable at the carburetor. Remove the accelerator cable bracket and the accelerator return spring.
11. Remove the bracket that secures the choke and throttle cables to the radiator bracket. Remove the accelerator cable retaining bracket from the radiator bracket and air deflector.
12. Disconnect the fuel line at the flex line, then remove the line. Disconnect the tachometer drive cable at the governor.
13. Remove the radiator inlet hose. Remove the fan assembly attaching bolts.
14. Remove the radiator shutter assembly, radiator, fan, and shroud.

On a vehicle with conventional brakes, disconnect the vacuum assist brake line at the intake manifold.

On a vehicle with power steering, disconnect the power steering return line at the pump reservoir and the pressure line at the pump housing. Drain the oil into a suitable container. Loosen the pump assembly and remove the drive belt.

On a vehicle with an air compressor, loosen the outlet line at the air compressor and allow the air to escape; then disconnect the line. Disconnect the air compressor governor line at the air compressor. Loosen the air compressor idler pulley and remove the drive belt. Remove the air compressor pulley.

15. Install the engine lifting eye bolts and sling (Fig. 7).
16. Disconnect the muffler inlet pipes at the exhaust manifold.
17. Remove the oil pan. Position a floor jack under the transmission with no pressure applied. Remove the flywheel housing dust cover and the flywheel housing-to-engine bolts.
18. Disconnect the parking brake clevis pin. Disconnect the engine front support at the frame crossmember.
19. Raise the engine approximately one inch and support the transmission with the jack.
20. Remove the engine from the chassis and install it on a work stand (Fig. 8).

Installation

1. Install guide pins in the two lower bolt holes in the cylinder block.
2. Place a new gasket over the exhaust manifold studs.
3. Attach the engine lifting eye bolts and sling (Fig. 7) and remove the engine from the work stand.
4. Carefully lower the engine into the chassis. Make sure the exhaust manifolds are properly aligned with the muffler inlet pipes and the guide pins in the cylinder block engage the holes in the flywheel housing.
5. Install two flywheel housing-to-engine bolts and remove the guide pins. Install the remaining bolts, then tighten all the bolts to specifications.
6. Install the engine front support bolts, washers, and nuts, then tighten them to specifications.
7. Remove the jack from the transmission. Install the flywheel housing dust cover and the parking brake clevis pin.
8. Install the starter. The engine ground strap is retained by the starter mounting at the starter shield bolt.
9. Connect the muffler inlet pipes to exhaust manifold. Install oil pan and the oil filter.
10. Remove the engine lifting eye bolts and sling.
11. Connect the fuel line to the flex line.

Connect the vacuum assist brake line at the intake manifold.

On a vehicle with an air compressor, install the air compressor pulley and the drive belt. Adjust the belt tension, then tighten the idler pulley. Connect the air compressor governor line and outlet at the air compressor.

On a vehicle with power steering, install the drive belt. Adjust the belt tension, then tighten the pump assembly. Disconnect the power steering return line at the pump housing, and connect the lines at the bracket on the frame left side member.

12. Install the alternator drive belts. Adjust the tension of the belts, then tighten the alternator mounting bolts and the adjusting arm bolts. Connect the alternator wires.
13. Install the oil pressure safety switch. Connect the oil pressure safety switch wires, the choke control cable, and the oil pressure and engine temperature sending unit wires.
14. Install the radiator and shroud assembly in the chassis with the fan positioned in the shroud.
15. Install the fan on the crankshaft damper. Install the radiator shutter assembly.
16. Connect the radiator outlet hose at the water pump and the radiator inlet hose at the intake manifold. Install the radiator drain cock.
17. Apply sealer to the heater return hose adapter and install the adapter in the water pump.
18. Connect the heater hose and install the retaining bracket on the intake manifold.
19. Install the radiator supply tank and bracket (with the coil). The cab lock release spring bracket is retained by the radiator supply tank upper bolt. Connect the radiator supply tank tube to the front thermostat housing. Connect the oil filter hose at the valve rocker arm cover. Connect the cab latch anti-rattle springs.
20. Connect the resistor, tachometer and distributor wires to the coil. Install the oil level dipstick.
21. Install the accelerator cable retaining bracket on the radiator bracket and air deflector. Install the bracket for the choke and throttle cable and tachometer wire on the radiator bracket. Install the accelerator retracting spring.
22. Connect the hand throttle control cable and the accelerator cable at the carburetor. Connect the tachometer drive cable.
23. Connect the battery ground strap.
24. Fill and bleed the cooling system. Fill the crankcase with proper grade and quantity of engine oil.

On a vehicle with power steering, fill the power steering pump following the recommended procedure.

25. Operate the engine at fast idle and check all gaskets and hose connections for leaks.
26. Install the air cleaner. Connect the closed positive crankcase ventilation hose, if so equipped. Lower and lock the cab.

LN AND LNT-SERIES

Removal

1. Support the hood and fender in a vertical position.
2. Disconnect the battery ground strap at the battery.
3. Drain the cooling system and the crankcase.
4. Disconnect the radiator upper hose

at the intake manifold and the radiator lower hose at the water pump.
5. Disconnect the crankcase ventilation system hose at the air cleaner, and remove the air cleaner assembly.
6. Remove two nuts attaching the radiator support rods to the radiator.
7. Bleed the air system and disconnect the lines from the shutterstat. Disconnect the power steering lines, if so equipped. Drain the oil into a suitable container.
8. Remove the bolts attaching the fan blade to the water pump hub. Remove the fan blade, pulley and belts.
9. Remove the nuts attaching the radiator support to frame crossmember.
10. Remove the bolts attaching the regulator to radiator support and position the regulator aside.
11. Remove the shutter, radiator and support assembly from the vehicle.
12. Disconnect the heater hoses at the water pump and at the intake manifold.
13. Disconnect the accelerator linkage at the pedal extension.
14. Disconnect the choke control and throttle control cables at the carburetor.
15. Disconnect the tachometer cable at the governor.
16. Disconnect the flex fuel line at the tank line.
17. Disconnect the fuel cut-off switch and the oil pressure sending unit wires.
18. Disconnect the temperature and safety switch wires fron the sending units.
19. Disconnect the coil secondary high tension wire from the coil and remove the bolt attaching the wiring harness to the intake manifold. Disconnect the coil primary wire from the coil. Position the harness out of the way.
20. Remove the nut attaching the alternator-ground wire to the alternator. Disconnect alternator lead wires.
21. Remove the nuts attaching the right exhaust inlet pipe to the exhaust manifold. Remove the pipe.
22. Remove the nuts attaching the left exhaust inlet pipe to the exhaust manifold. Remove the pipe.
23. Disconnect the starter cable at the starter and remove the starter shield and starter.
24. Remove the bolts attaching the flywheel housing cover to the engine and flywheel housing.
25. On a vehicle equipped with an air compressor, loosen the outlet line at the air compressor and allow the air to escape, then disconnect the line. Disconnect the air compressor governor line at the air compressor.
26. Remove the engine front support attaching bolts, nuts and washers.
27. Remove the accelerator retracting spring and the fuel inlet line from the carburetor.
28. Disconnect the distributor vacuum line at the carburetor and the governor control rod from the carburetor.
29. Remove the nuts and washers attaching the carburetor to the intake manifold and remove the carburetor.
30. Install eye bolts in the left front and right rear cylinder head tapped holes. Attach lifting tool 6000-BE.
31. Position the floor crane to the engine and attach the chain to the lifting tool.
32. Position a floor jack under the transmission and raise it approximatley 1/2 inch.
33. Remove the bolts attaching the engine to the flywheel housing.
34. Remove the engine from the vehicle.

Installation

1. Attach the engine lifting eye bolts and sling and remove the engine from the work stand.
2. Carefully lower the engine into the chassis. Make sure the exhaust manifolds are properly aligned with the muffler inlet pipes, and that the clutch disc is properly centered (Group 16).
3. Install the bolts that attach the engine to the flywheel housing and tighten to specifications.
4. Remove the lifting sling and eye bolts from the engine.
5. Remove the jack from under the transmission.
6. Install the engine front support bolts, washers, and nuts, then tighten them to specifications.
7. Position the carburetor to intake manifold gasket on the manifold, and install the carburetor with the washers and nuts.
8. Connect the governor control rod to the carburetor.
9. Connect the distributor vacuum line and fuel inlet line to the carburetor.
10. Connect the tachometer cable to the governor.
11. Connect the throttle cable and choke to the carburetor. Connect the accelerator retracting spring.
12. Connect the accelerator linkage to pedal extension.
13. Connect the lead wires and ground wire to the alternator.
14. Position the wiring harness to the engine and connect the temperature sending unit, safety switch, and coil. Install a ground bolt to the intake manifold. Connect the coil secondary high tension wire to the coil.
15. On a vehicle equipped with an air compressor, connect the outlet line and governor line to the compressor. On a vehicle equipped with power steering, connect the power steering lines.
16. Connect the fuel line to the tank line.
17. Position the starter gasket and install the starter to the engine with one bolt, washer, and nut. Do not tighten.
18. Install the starter shield and tighten the starter attaching nuts and bolts.
19. Connect the starter cable to the starter.
20. Install the flywheel housing cover and attaching bolts.
21. Position the left exhaust manifold to muffler inlet pipe gasket and connect the pipe to the manifold.
22. Position the right exhaust manifold to muffler inlet pipe gasket and connect the pipe to the manifold.
23. Position the radiator shutter, radiator, and support assembly in the vehicle.
24. Install the washers and nuts attaching the radiator support to the crossmember.
25. Install the water pump pulley, drive belts and fan.
26. Connect the radiator lower hose to the water pump and the upper hose to the intake manifold.
27. Connect the heater hose to the water pump and the intake manifold.
28. Adjust the belt tension.
29. Connect the radiator support rods to the radiator support.
30. Connect the lines to the shutterstat.
31. Install the air cleaner assembly. Connect the crankcase ventilation system hose to the air cleaner.
32. Install the regulator on the radiator support.
33. Fill and bleed the cooling system.
34. Fill the crankcase with the proper grade and quantity of engine oil.

On a vehicle with power steering, fill the power steering pump following the recommended procedure.

35. Connect the battery ground strap to the battery.
36. Operate the engine at fast idle and check all gaskets and hose connections for leaks. Make necessary adjustments.
37. Close the hood and fenders and lock in place.

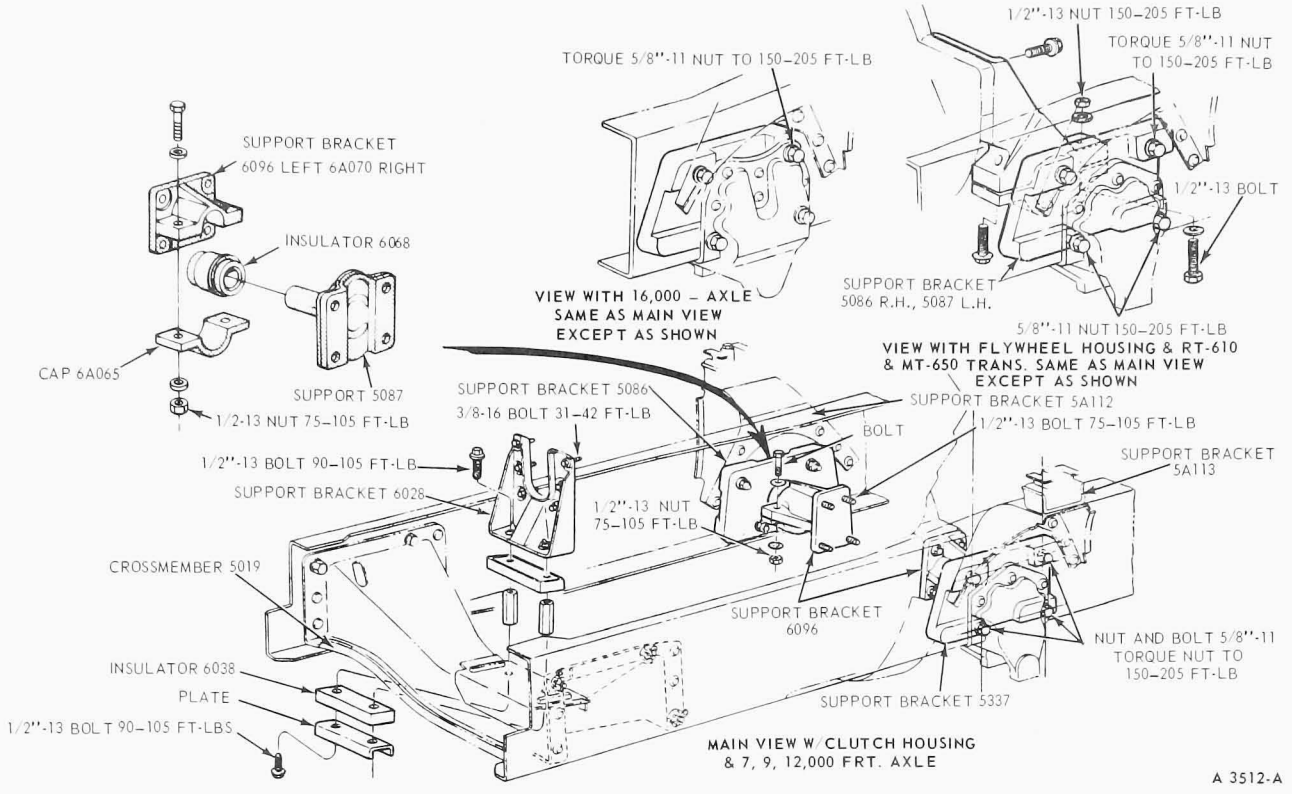


FIG. 9 Engine Supports—L, LT, LTS, LN and LNT-Series

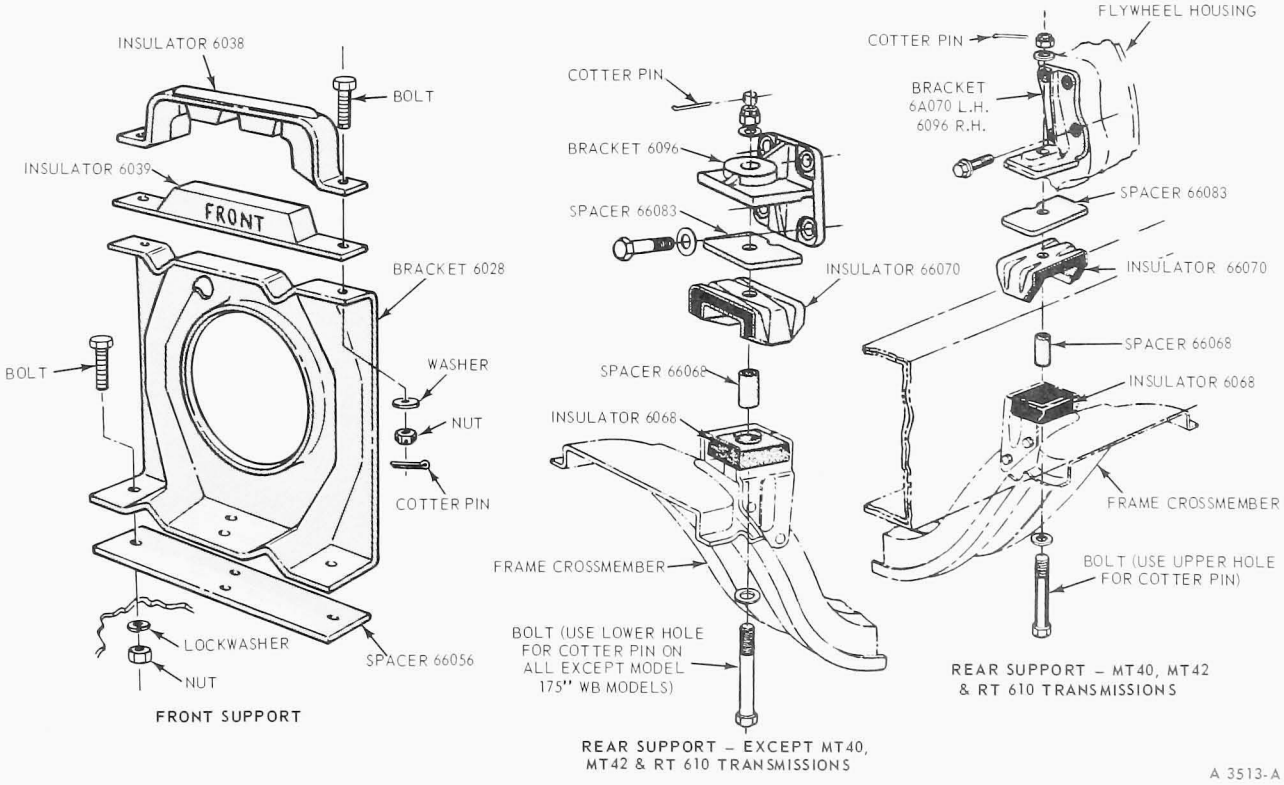

FIG. 10 Engine Supports—C and CT-Series

ENGINE FRONT SUPPORTS

The engine is supported at the front and on each side at the rear of the crankcase (Figs. 9 and 10).

L, LT, LTS, LN AND LNT-SERIES

Removal

1. Remove the two upper insulator attaching bolts (Fig. 9).
2. Remove the two lower insulator attaching bolts and remove the lower insulator, spacers and plate.
3. Place a wood block on a jack, then raise the engine high enough to remove the upper insulator.

Installation

1. Torque the engine support bracket-to-crossmember attaching bolts to specification.
2. Position a new upper insulator on the support bracket (Fig. 9).
3. Lower the engine enough to start the attaching bolts and washers in the spacers, then remove the jack.
4. Secure the lower insulator and plate to the support bracket with the attaching bolts and washers. Torque the four insulator attaching bolts to specification.

C AND CT-SERIES

Removal

1. Disconnect the alternator adjusting arm at the engine front support insulator and remove the air compressor idler pulley.
2. Remove the front support insulators to front support bracket cotter pins, attaching nuts, flat washers and bolts (Fig. 10).
3. Position a jack and wood block under the oil pan and raise the engine slightly.
4. Remove the upper and lower insulators.

Installation

1. Position the upper and lower insulators on the front support bracket.
2. Install, but do not tighten, the front support insulator bolts, flat washers, and nuts.
3. Lower the engine and remove the jack and wood block. Tighten the nuts and attaching bolts to specifications and insert new cotter pins.
4. Connect the alternator adjusting arm and install the air compressor idler pulley.
5. Adjust the drive belts.

ENGINE REAR SUPPORTS

L, LT, LTS, LN AND LNT-SERIES

Removal

1. Remove the two capscrews from the engine rear support bracket and remove the cap.
2. Place a wood block on a jack and raise the rear of the engine just enough to remove the weight from the rear supports.
3. Remove the four bolts that attach the engine rear support to the frame side rail and remove the support and insulator.

Installation

1. Position a new insulator on the engine rear support (Fig. 9). Position the support and insulator to the frame side rail. Install and torque the attaching bolts to specification.
2. Lower the engine and remove the jack.
3. Install and torque the capscrews in each engine rear support bracket and cap.

C AND CT-SERIES

Removal

1. Remove the cotter pin from the engine rear mount bolt, then remove the mounting bolt, lower insulator, and spacer (Fig. 10).
2. Position a jack under the transmission and raise the rear of the engine.
3. Remove the upper insulator.

Installation

1. Position the upper insulator.
2. Lower the rear of the engine and remove the jack.
3. Align the rear of the engine with a drift pin and position the lower insulator and spacer.
4. Install the engine mounting bolt and nut and tighten them to specifications.
5. Install a new cotter pin in the mounting bolt. Be sure the cotter pin is in the correct hole in the bolt according to the vehicle model. The hole nearest the end of the mounting bolt is used for 175 inch wheel base. The other hole is used for the remainder of the vehicle series.

OIL COOLER

Removal

1. Drain the cooling system.
2. Remove the oil cooler cover and gasket and the oil cooler and gasket.
3. Remove the relief valve plug and gasket; then remove the spring and plunger. The oil cooler assembly is shown in Fig. 11.

Installation

1. Install the relief valve plunger (with the open chamber up), spring, gasket and plug in the cover.
2. Place a new cooler gasket, with sealer on both sides, on the block. Position the oil cooler in the block.
3. Place a new cover gasket on the cover with sealer on both sides and install the cover, then tighten the cover bolts to specifications.
4. Open the air bleed valve at the front of the intake manifold and fill and bleed the cooling system.

CRANKCASE VENTILATION REGULATOR VALVE

Removal

1. Remove the crankcase ventilation exhaust tube by disconnecting the exhaust tube from the crankcase ventilation outlet and from the regulator valve in the intake manifold (Fig. 12).
2. Remove the regulator valve assembly and the rubber connection.

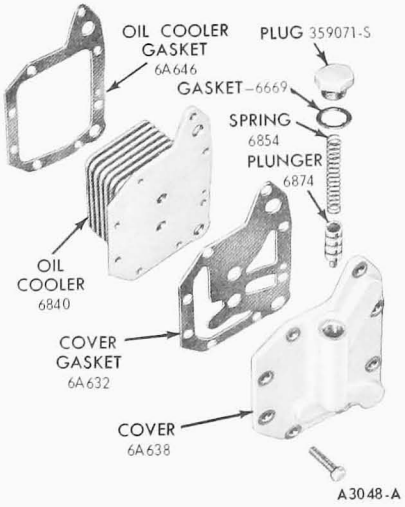

FIG. 11 Oil Cooler Assembly

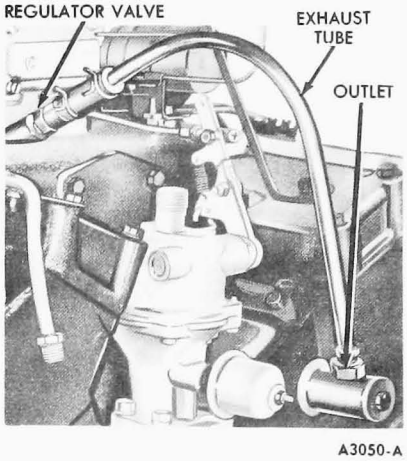

FIG. 12 Crankcase Ventilation System Regulator Valve Installed

Installation

1. Install the regulator valve in the intake manifold.
2. Position and install the rubber connection and exhaust tube on the engine.

VALVE ROCKER ARM COVER AND ROCKER ARM

Removal

Because five cylinder head bolts also serve to retain the pedestals for the valve rocker arm shaft assembly, each time the valve rocker arm shaft assembly is removed, the cylinder head gasket must be replaced.

1. Follow steps 1 thru 4 under Cylinder Head Removal.
2. Release the spring tension on the valve rocker arms by loosening the adjusting screws.
3. Remove the valve rocker arm shaft assembly and the oil baffle plate.
4. Follow steps 7 thru 10 under Cylinder Head Removal.

Installation

1. Follow steps 1 thru 7 under Cylinder Head Installation.
2. Position the oil baffle plate and the valve rocker arm shaft assembly on the cylinder head. Install the bolts and flat washers but do not tighten.
3. Follow steps 9 thru 17 under Cylinder Head Installation.

INTAKE MANIFOLD

Removal

1. Drain the cooling system. Disconnect the radiator upper hose at the water pump.
2. Remove the clamp retaining the radiator shutter air lines to the cross braces. Remove the cross braces.
3. Disconnect the air tubes at the carburetor air duct, then remove the air duct assembly.

On a tilt cab, unclamp the oil filler hose at the valve rocker arm cover, then remove the oil filler hose and radiator supply tank, brackets, and hoses. Disconnect the hose at the air cleaner and remove the air cleaner and brackets.

4. Disconnect the coil secondary high tension lead and the distributor primary wire at the coil.
5. Remove the distributor cap and spark plug wires as an assembly.
6. Remove the cooling system air vent lines.
7. Disconnect the heater hoses at the engine and the radiator inlet and outlet hoses.
8. Remove the coil bracket attaching bolts and washers and disconnect the wire at the temperature sending unit, then position the coil assembly and sending unit wire out of the way.
9. Disconnect the choke control cable at the carburetor and the governor control rod at the governor. Disconnect the vacuum assist brake line and the positive crankcase ventilation exhaust tube at the intake manifold.
10. Disconnect the accelerator linkage at the accelerator assembly and the hand throttle control cable at the carburetor. Remove the accelerator retracting spring.
11. Disconnect the oil pressure safety switch wires.
12. Disconnect the carburetor fuel inlet line and remove the retaining clamps from the manifold.
13. Slide the clamp on the intake manifold coolant outlet hose toward the water pump.
14. Disconnect the tachometer cable at the governor and position the cable out of the way.
15. Remove the intake manifold attaching bolts, then remove the intake manifold and carburetor as an assembly.

Installation

The intake manifold assembly is shown in Fig. 13.

1. Clean the intake manifold gasket surfaces. Apply sealer to the intake manifold gaskets and position them on the cylinder heads.
2. Position the intake manifold and carburetor as an assembly on the cylinder heads. Install the bolts and lock washers, then tighten the bolts to specifications.
3. Connect the crankcase ventilation exhaust tube.
4. Connect the carburetor inlet line and retaining clamps. Connect the oil pressure safety switch wires.
5. Install the accelerator retracting spring. Connect the hand throttle control cable, the accelerator linkage and the tachometer cable.
6. Connect the choke control cable, the governor and control rod, the heater hoses, and the radiator hoses.
7. Install the coil and connect the temperature sending unit wire. Connect the distributor primary wire and coil high tension lead at the coil. Connect the vacuum assist brake line.
8. Install the cooling system air vent lines, and the distributor cap and spark plug wire assembly. Connect the radiator upper hose.
9. Install the cross braces and the clamp retaining the radiator shutter air lines.

On a tilt cab, install the air cleaner and brackets. Install the radiator support tank, bracket, and hoses. Connect the oil filler hose to the valve rocker arm cover.

10. Open the air bleed valve at the front of the intake manifold. Fill the cooling system. When coolant is discharged at the bleed valve, close it finger tight. Operate the engine at fast idle and check for coolant leaks.
11. Install the carburetor air duct assembly and connect the air tubes. Connect the hose to the air cleaner.

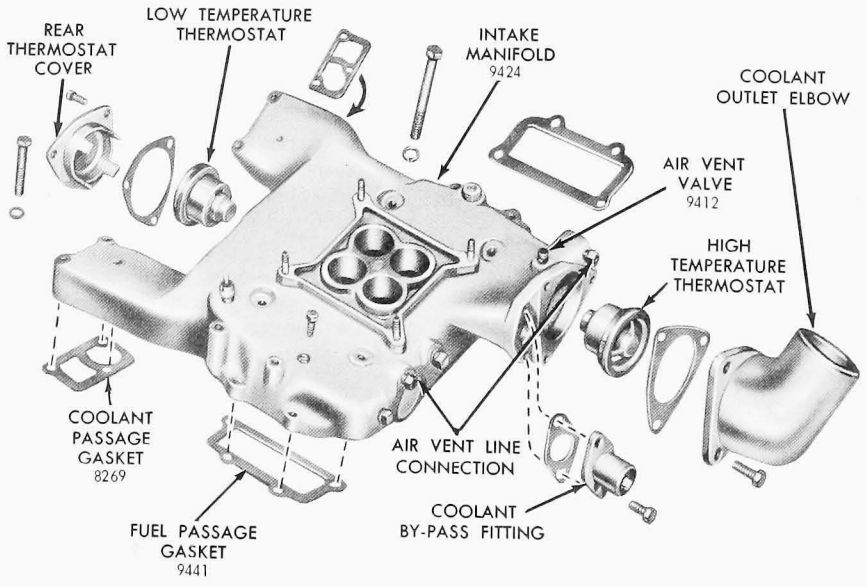

FIG. 13 Intake Manifold Assembly

EXHAUST MANIFOLDS

Removal

1. Disconnect the exhaust manifold(s) at the muffler inlet pipe(s).
2. Straighten the lock tab on the washers. Remove the exhuast manifold attaching bolts and remove the exhaust manifold and heat shield.

Installation

1. Clean the mating surfaces of the exhaust manifold and cylinder head. Scrape the gasket material from the mounting flange of the exhaust manifold and muffler inlet pipe. Position a new muffler inlet pipe gasket over the studs of the exhaust manifolds.
2. Apply graphite grease to the mating surface of the exhaust manifold. Position the heat shield and exhaust manifold on the cylinder head. Connect the exhaust manifold to the muffler inlet pipe. Install the exhaust manifold tab washers and attaching bolts. Torque the bolts to specifications, working from the center to the ends. Lock the bolts by bending one tab on the washer over a flat on the bolt. Install the muffler inlet pipe lock washers and attaching nuts. Torque the nuts to specifications.

CYLINDER HEADS

Removal

1. Remove the intake manifold assembly following the procedure under Intake Manifold Removal.
2. Remove the air cleaner and support bracket. Disconnect the oil pressure sending unit wire and tachometer cable at the governor. Remove the governor.
3. Remove the valve push rod cover and valve rocker arm covers.
4. Disconnect the muffler inlet pipes at the exhaust manifolds.
5. Release the spring tension on the valve rocker arm by loosening the adjusting screws.
6. Remove the valve rocker arm shaft assembly and the oil baffle plate.
7. Remove the valve push rods in sequence (Fig. 14).
8. Install standard eye bolts with 5/8-18 threads in he cylinder head and attach the engine lifting sling (Fig. 15).
9. Remove the remaining cylinder head bolts. Raise the cylinder head and remove it from the engine. Remove and discard the cylinder head gasket.
10. Place the cylinder head on a work bench and remove the exhaust manifold and heat shield. Install the holding fixtures.

Installation

1. Clean the cylinder head and cylinder block gasket surfaces. Coat the threads of the cylinder head bolts with engine oil.
2. Remove the cylinder head holding fixtures and install the heat shield and the exhaust manifold. Install the spark plugs.
3. Install standard eye bolts with 5/8-18 threads in the cylinder head and attach the engine lifting sling.
4. Guided by the word TOP on the gasket, install the gasket over the cylinder head dowels. **Gasket sealer must not be used on the cylinder head gasket.**
5. Position the cylinder head on the engine (Fig. 15). **Slide the flat washers on the cylinder head bolts.**
6. Install the five outside bolts with the flat washers but do not tighten. Remove the lifting sling and eye bolts.
7. Apply Lubriplate or equivalent to both ends of the push rods. Install the push rods in their proper sequence making sure the lower ends are positioned in the tappet socket.
8. Position the oil baffle plate and the valve rocker arm shaft assembly on the cylinder head. Install the remaining five cylinder head bolts with flat washers but do not tighten.
9. The cylinder head bolt tightening procedure is performed in three progressive steps. Follow the sequence shown in Fig. 16. Tighten the bolts to specification. When the cylinder head bolts have been tightened following this procedure it is not necessary to retorque them after extended operation. They may, however, be checked and retorqued if desired.
10. Perform a preliminary valve clearance adjustment. Install the governor. Connect the tachometer cable and oil pressure sending unit wire.
11. Coat one side of the valve push rod cover gasket with oil-resistant sealer. Lay the cemented side of the gasket in place on the block and cylinder head. Position the cover making sure that the gasket seats evenly all around the block. Install the bolts with new washers. Be sure the washers are installed with the rubber side toward the cover. Tighten the bolts following the sequence in Fig. 17.
12. Install the intake manifold and related parts following steps 1 thru 8 under Intake Manifold Installation.

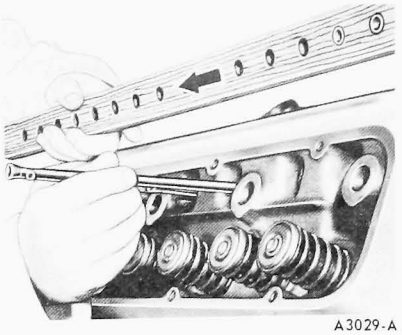

FIG. 14 Removing Push Rod

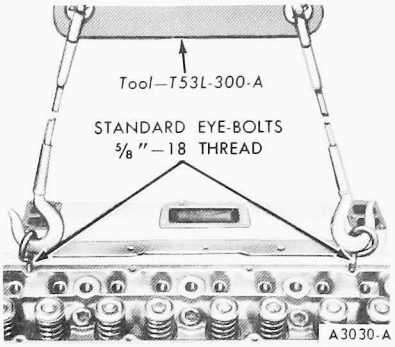

FIG. 15 Removing or Installing Cylinder Head

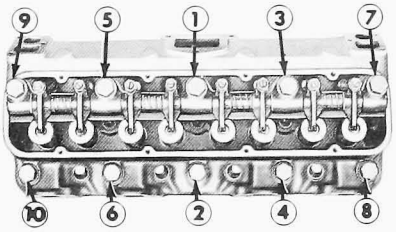

FIG. 16 Cylinder Head Bolt Tightening Sequence

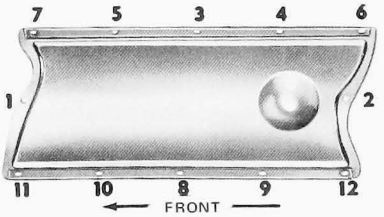

FIG. 17 Valve Push Rod Cover Bolt Tightening Sequence

13. Connect the muffler inlet pipes to the exhaust manifolds.
14. Open the air bleed valve at the front of the intake manifold and fill and bleed the cooling system. Operate the engine until the engine temperatures have stabilized. Check the valve clearance when engine temperatures are stabilized with the engine idling and adjust it if necessary.
15. Check all hose connections and gaskets for leaks. Coat one side of the valve rocker arm cover gaskets with oil-resistant sealer, and lay the cemented side of the gaskets in place in the covers.
16. Install the valve rocker arm covers, making sure that the gaskets seat evenly all around the head. Install the attaching screws and tighten them to specifications. Install the air cleaner and support brackets.
17. Adjust the engine idle speed and fuel mixture.

VALVE SPRING, RETAINER AND STEM SEAL

Broken valve springs or leaking or damaged valve stem seals and retainers may be replaced without removing the cylinder head, provided damage to the valve or valve seat has not occurred.

Removal

1. Remove the air cleaner and the valve rocker arm cover.
2. Remove the applicable spark plug. Install an auxiliary starter switch. **Crank the engine with the ignition switch off.**
3. Crank the engine until the applicable piston is on TDC after the compression stroke. Be sure that both valves are closed. **Be sure that the piston is on TDC to prevent the crankshaft from turning when the air is applied.**
4. Backout the adjustment screw and remove the push rod. Install an air line with an adapter in the spark plug hole.
5. Push the rocker arm to one side and secure it in this position.
6. Turn on the air supply. Using the valve spring compression tool (tool K-D915), compress the valve and remove the valve spring retainer locks, the sleeve, spring retainer, and the valve spring.
7. Remove the valve stem seal.

Installation

1. Install a new valve stem seal. Place the spring in position over the valve. Install the spring retainer and sleeve. Compress the valve spring and install the valve spring retainer lock.
2. Apply Lubriplate or equivalent to both ends of the push rod. Install the push rod, making sure the lower end of the rod is positioned in the tappet push rod cup.
3. Remove the wire securing the valve rocker arm and slide the rocker arm into position. Turn off the air and remove the air line and adapter. Install the spark plug and spark plug wire.
4. Perform a preliminary valve clearance adjustment (Part 21-01).
5. Temporarily install the valve rocker arm cover and connect the spark plug wires.
6. Start the engine, and after engine temperatures are stabilized, perform a hot valve clearance adjustment (Part 21-01).
7. Install the air cleaner.

VALVE LIFTERS

Removal

1. Drain the cooling system.
2. Remove the intake manifold and valve push rod cover following the procedure outlined in this section.
3. Remove the valve rocker arm covers.
4. Back off the valve clearance adjusting screws, turning the crankshaft damper as necessary to follow the firing order and remove the valve push rods keeping them in order so that they can be installed in their original locations.
5. Remove and replace one tappet at a time. If the tappets are difficult to remove, use the tool shown in Fig. 18. Apply Lubriplate or equivalent to each tappet foot. Then coat the remainder of each tappet and tappet bore with heavy engine oil before installation.

Installation

1. Install the valve push rod cover by following step 11 under Cylinder Head Installation.
2. Lubricate each end of the push rods with Lubriplate or equivalent. Install the valve push rods (in sequence) and the intake manifold following the procedure under Intake Manifold Installation.
3. Perform a preliminary valve clearance adjustment (Part 21-01). Install the distributor cap and connect the spark plug wires and the coil secondary high tension lead.
4. Open the air bleed valve at the front of the intake manifold and fill and bleed the cooling system. Start the engine. Adjust the ignition timing. Check the hose connections and gaskets for leaks.
5. Operate the engine until the engine temperatures have stabilized. Check and adjust the valve clearance. Install the air cleaner. Adjust the engine idle speed and fuel mixture.

WATER PUMP

Removal

1. Drain the cooling system. Disconnect the radiator lower hose, heater hose, and the water by-pass hose at the water pump. Remove the fan belt(s).

On L-and LT-Series vehicles, remove the fan and pulley and lower them into the bottom of the radiator shroud. Remove the bolts attaching the water pump to the water pump housing and remove the water pump and gaskets.

On C-Series vehicles, remove the water pump attaching bolts and remove the water pump, pulley, and gaskets as an assembly.

Installation

Before a water pump is re-installed, check it for damage. If it is damaged and requires repair, replace it with a new pump or install a rebuilt pump obtained from a Ford-Authorized Reconditioner.

1. Position new gaskets coated on both sides with water-resistant sealer, on the water pump housing, then install the water pump. Install the attaching bolts and torque them to specifications. Install the fan and pulley on the hub, then install the fan belt(s). Adjust the belt tension.

On C-Series vehicles, install the water pump, pulley, and gaskets as an assembly.

2. Connect the radiator lower hose, heater hose, and water by-pass hose to the water pump. Open the air bleed valve at the front of the intake manifold and fill and bleed the cooling system, warm up the engine, and check for leaks.

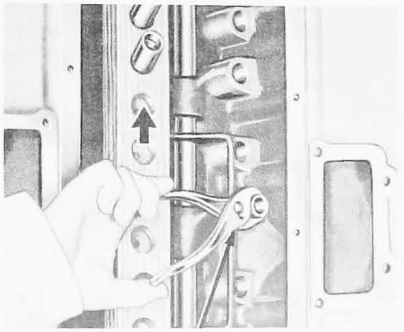

FIG. 18 Removing Tappet

CYLINDER FRONT COVER AND TIMING GEARS

Removal

1. Drain the cooling system and the crankcase.
2. Remove the fan, shroud, radiator and radiator shutter.
3. Remove the alternator, power steering pump, and air compressor drive belts.

On the L-or LT-Series vehicles, remove the upper front support insulator attaching bolts. Lift the front of the engine approximately one inch with a floor jack to allow removal of the damper.

4. Remove the damper capscrew and washer. Install the removal tool and remove the damper (Fig. 19).
5. Remove the air compressor idler pulley and disconnect the alternator adjusting arm at the cylinder front cover.
6. Remove the water pump and housing as an assembly.
7. Remove the engine front support bracket, and the oil level dipstick.
8. Remove the bolts fastening the cylinder front cover to the block and to the oil pan. Using a thin bladed knife cut the oil pan gasket flush with cylinder block face prior to separating the cover from the cylinder block. Remove the cylinder front cover.
9. Discard the cylinder front cover gasket.
10. Remove the crankshaft front oil slinger.
11. Check the backlash between the camshaft gear and the crankshaft gear with a dial indicator. Hold the gear firmly against the block while making the check. Refer to the specifications for the backlash limits.
12. Check the camshaft and crankshaft gear runout with a dial indicator. If the gear runout is excessive, replace the gear or gears.
13. Align the timing marks on the timing gears (Fig. 20). Remove the camshaft gear attaching bolts, then remove the camshaft gear.
14. To remove the crankshaft gear, install the tool shown in Fig. 21 and pull the gear off the shaft.

Installation

1. Install the crankshaft gear (Fig. 22) and the camshaft gear with the timing marks aligned (Fig. 20), then install the camshaft gear attaching bolts. **The bolts are unequally spaced. Tighten the bolts to specifications.**
2. Install the crankshaft front oil slinger.
3. Clean all oil pan and cylinder block-to-front cover gasket surfaces.
4. Coat the gasket surface of the oil pan with sealer, cut and position the required section of a new gasket on the oil pan, apply sealer at the corners.
5. Coat the gasket surfaces of the block and cover with sealer, and position a new gasket on the block.
6. Position the cylinder front cover on the cylinder block. **Use care when installing the cover to avoid seal damage or possible gasket mislocation.**
7. Install the cylinder front cover-to-seal alignment tool into proper position. It may be necessary to force the cover downward in a manner to slightly compress the pan gasket. This operation can be facilitated by using a suitable tool at the cover attaching bolt hole locations in the cylinder block.
8. Coat the threads of the attaching bolts with oil-resistant sealer. While

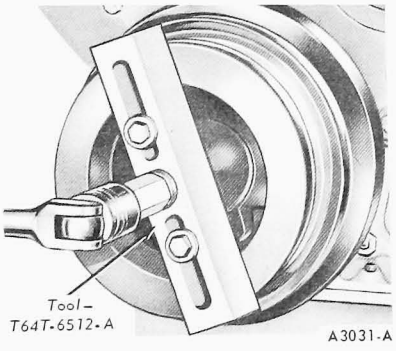

FIG. 19 Removing Damper

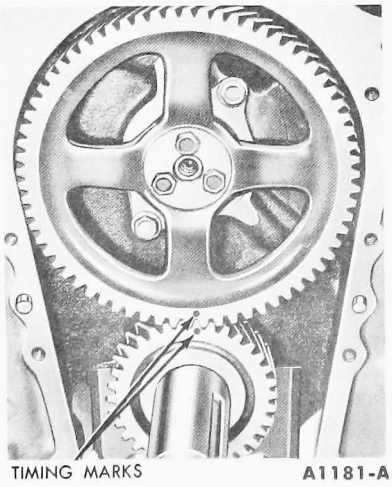

FIG. 20 Timing Mark Alignment

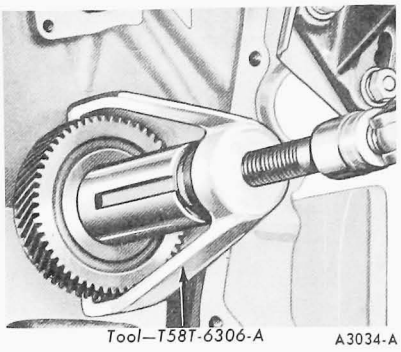

FIG. 21 Removing Crankshaft Gear

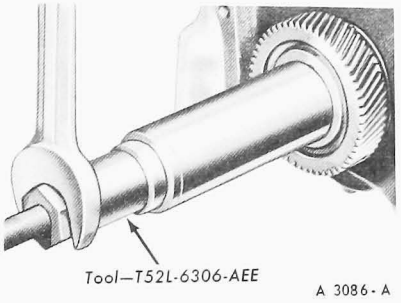

FIG. 22 Installing Crankshaft Gear

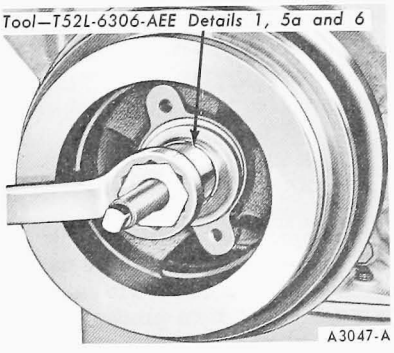

FIG. 23 Installing Damper

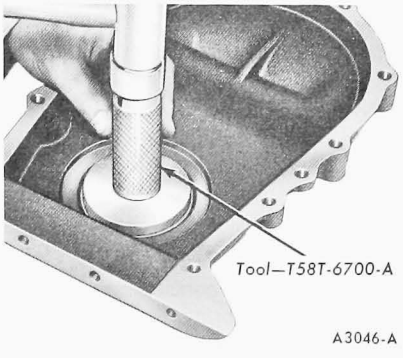

FIG. 24 Installing Oil Seal

pushing in on the pilot, install and torque the oil pan-to-cover attaching bolts to specifications. Install and torque the cover attaching bolts to specification. Remove the pilot.
9. Install the engine front support bracket.
10. Apply sealer to the water pump housing gasket and position it on the block; then install the water pump and housing assembly.
11. Install the air compressor idler pulley and the alternator adjusting arm on the cylinder front cover.
12. Lubricate the crankshaft with a white lead and oil mixture and lubricate the oil seal rubbing surface with grease.
13. Clean and inspect the oil sealing surface on the crankshaft damper hub, following the procedures in Part 21-01. Apply Lubriplate or equivalent to this surface. Align the damper keyway with the key on the crankshaft, then install the damper (Fig. 23).
14. Install and adjust the drive belts.
15. Install the fan, shroud, radiator and radiator shutter.
16. Fill and bleed the cooling system.
17. Fill the crankcase with the proper grade and quantity of engine oil.

FRONT OIL SEAL

It is good practice to replace the oil seal each time the cylinder front cover is removed.
1. Drive out the old seal with a pin punch.
2. Clean out the recess in the cover.
3. Coat a new seal with grease (Fig. 24). Drive the seal in until it is fully seated in the recess. Check the seal after installation to be sure the spring is properly positioned in the seal.

CAMSHAFT

Removal
1. Following the procedures outlined in their respective sections, remove the intake manifold and the cylinder front cover.
2. Turn the crankshaft as necessary to follow the firing order, then back off the valve clearance adjustment screw. Slide the rocker arm to one side and remove the valve push rods in sequence.
3. Remove the distributor and governor. Remove the push rod cover.
4. Remove the valve tappets keeping them in order so that they can be replaced in their original position (Fig. 18).
5. Remove the crankshaft front oil slinger. Align the timing marks on the camshaft and crankshaft timing gears (Fig. 20).
6. Remove the camshaft thrust plate attaching bolts. Remove the camshaft gear, spacer, thrust plate and camshaft as an assembly (Fig. 25).

Installation

The camshaft and related parts are shown in Fig. 26.

If a new camshaft is to be installed, remove the gear, spacer, and thrust plate from the old camshaft and install them on the new camshaft. Apply a coating of Lubriplate or equivalent to each camshaft lobe. Apply heavy engine oil to each camshaft bearing journal and to each bearing in the cylinder block.
1. Oil the camshaft bearing journals and apply Lubriplate or equivalent to all the lobes as detailed above then carefully slide it through the bearings. Be sure the camshaft is installed so that the timing mark on the camshaft gear is aligned with the timing mark on the crankshaft gear (Fig. 20).

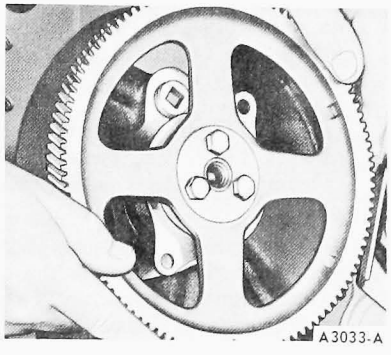

FIG. 25 Removing or Installing Camshaft

2. Install the thrust plate attaching bolts and torque them to specifications. Check the camshaft end play and gear backlash.
3. Install the crankshaft front oil slinger. Install the cylinder front cover and related parts and the crankshaft damper following the procedure under Cylinder Front Cover and Timing Gears Installation.
4. Apply Lubriplate or equivalent to the foot of each tappet. Coat the tappet bore and the remainder of each tappet with heavy engine oil. Install the valve tappets in sequence.
5. Lubricate the ends of each push rod with Lubriplate or equivalent. Install the push rods in sequence.
6. Perform a preliminary valve clearance adjustment.
7. Install the valve push rod chamber gasket and cover by following step 11 under Cylinder Head Installation. Install the governor.
8. Install the water pump, and the oil level dipstick.
9. Crank the engine until No. 1 piston is on TDC.
10. Install the governor and position the distributor in the block with the rotor at the No. 1 firing position with the breaker points open. Install the distributor hold-down clamp.
11. Install the intake manifold assembly and related parts following the procedure under Intake Manifold Installation.
12. Install the distributor cap and connect the spark plug wires and the coil secondary high tension lead.
13. Install the radiator shutter, fan, shroud, and radiator.
14. Open the air bleed valve at the front of the intake manifold. Fill the cooling system. When coolant is

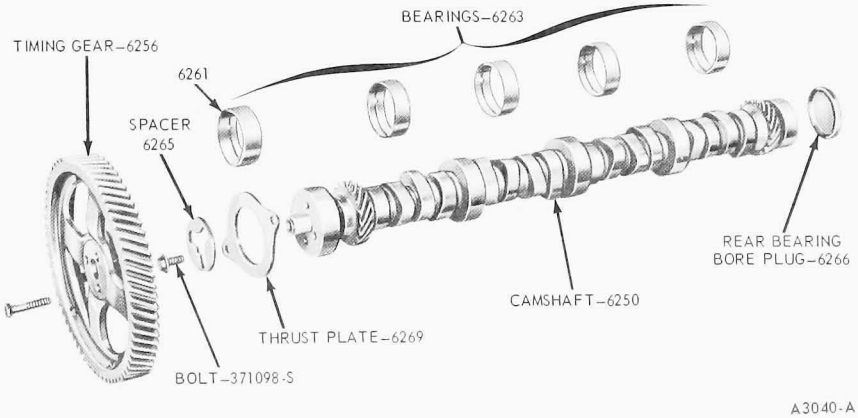

FIG. 26 Camshaft Assembly

discharged at the bleed valve, close it finger tight.

15. Start the engine. Adjust the ignition timing. Check all hose connections and gaskets for leaks.
16. Operate the engine until the engine temperatures have stabilized, then check and adjust the valve clearance.
17. Install the valve rocker arm covers and the air cleaner.

FLYWHEEL

Removal

1. Remove the transmission from the flywheel housing (Group 16).
2. Remove the clutch from the flywheel (Group 16). After these components are removed, remove the flywheel attaching bolts and remove the flywheel through the bottom of the housing.

Installation

1. Install the flywheel on the crankshaft flange, then tighten the attaching bolts to specifications.
2. To check flywheel face runout or replace flywheel ring gear for manual-shift transmissions, refer to Part 21-01.
3. Install the clutch (Group 16) and the transmission (Group 16). Install the flywheel housing dust cover.

CLUTCH PILOT BUSHING

Removal

1. Disconnect the transmission from the engine and slide it to the rear as outlined in Group 16.
2. Remove the pressure plate and the clutch disc.
3. Remove the pilot bushing.
4. Coat the pilot bushing bore in the crankshaft with a small quantity of wheel bearing lubricant. Avoid using too much lubricant because it may be thrown onto the clutch disc when the clutch rotates.

Installation

1. Install the replacement bushing.
2. Install the clutch disc and the pressure plate assembly.
3. Connect the transmission to the engine (Group 16).

CAMSHAFT BEARING BORE PLUG

Removal

1. Slide the transmission to the rear and remove the clutch pressure plate and disc.
2. Remove the flywheel attaching bolts and remove the flywheel.
3. Follow the instructions in Part 21-01, Core Plug Replacement to install the plug.

Installation

1. Install the flywheel.
2. Install the clutch pressure plate and disc, and install the transmission.

OIL PAN AND OIL PUMP

Removal

1. Drain the oil from the crankcase and remove the oil level dipstick. Remove the oil pan and discard the gasket.
2. If the oil pump is to be removed, remove the oil pump and pick-up tube assembly. Discard the oil pump gasket. Remove the intermediate drive shaft from the engine.

Installation

1. Insert the oil pump drive shaft (intermediate shaft) into the oil pump.
2. Position a new gasket on the pump housing, prime the pump by filling the inlet opening with oil and rotate the pump shaft until oil emerges from the outlet opening. Install the oil pump, shaft, and pick-up tube as an assembly (Fig. 27). **Do not attempt to force the pump into position if it will not seat readily. The drive shaft hex may be misaligned with the distributor shaft. To align, rotate the intermediate shaft into a new position.**
3. Tighten the oil pump attaching bolts to specifications. Remove the oil gasket from the oil pan and block gasket surfaces. Position a new gasket on the oil pan.
4. Hold the oil pan in place against the cylinder block and install two of the attaching bolts on each side of the pan. Install the remaining bolts and tighten them from the center outward to specifications.
5. Fill the crankcase and install the oil level dipstick. Operate the engine and check for oil leaks.

CRANKSHAFT REAR OIL SEAL

To correct an oil leakage condition both the upper and lower crankshaft rear seals must be replaced. Remove the engine; then, remove the crankshaft and replace the seals, following the procedure under Crankshaft Removal and Installation.

If only the main bearings are being replaced while the engine is in the vehicle, it is generally only necessary to replace the lower seal.

MAIN BEARING

The main and connecting rod bearing inserts are selective fit. **Do not file or lap bearing caps or use shims to obtain the proper bearing clearance. Bearings are available for service in standard sizes, 0.001 and 0.002 inch undersize. Refer to the Parts Catalog for other available undersize bearings. Undersized bearings are available for use on journals that have been refinished. Bearings should be checked and fitted to the crankshaft with Plastigage as detailed in Part 21-01 prior to final installation in the engine.**

Removal

1. Drain the crankcase. Remove the oil pan following the procedures under Oil Pan and Oil Pump Removal.
2. **Replace one bearing at a time, leaving the other bearing securely fastened.** Remove the main bearing cap to which new bearings are to be installed.
3. Insert the upper bearing removal tool (Tool 6331E) in the oil hole in the crankshaft journal.
4. Rotate the crankshaft slowly in the direction of engine rotation to force the bearing out of the block.

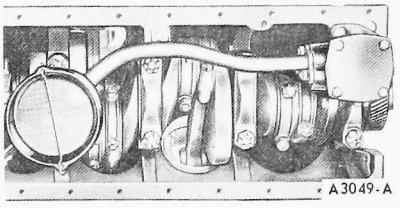

FIG. 27 Oil Pump and Pick-Up Tube Installed

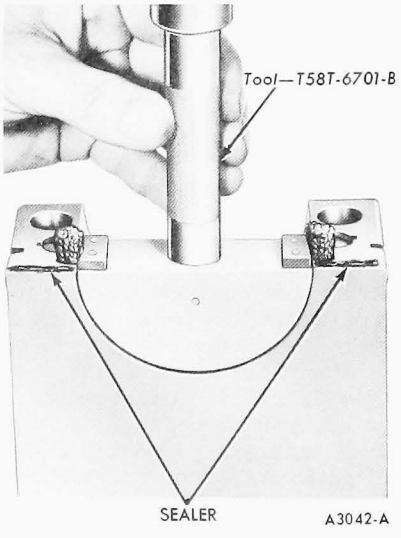

FIG. 28 Installing Seal in Rear Bearing Cap

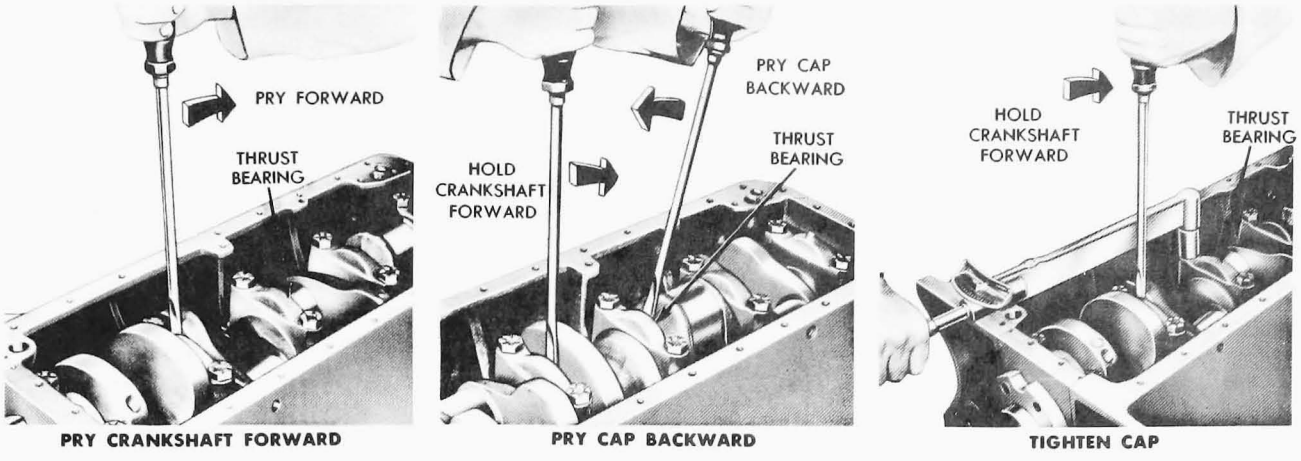

FIG. 29 Aligning Thrust Bearing

5. Clean the crankshaft journal and bearing inserts.

Installation

1. To install the upper main bearing, place the plain end of the bearing over the shaft on the locking tang side of the block. Using Tool 6331E in the oil hole in the crankshaft journal, rotate the crankshaft slowly in the opposite direction of engine rotation until the bearing seats itself. Remove the tool.
2. After the bearing has been checked with Plastigage and found to be satisfactory, apply a light coat of heavy engine oil to the journal and bearings, then install the bearing cap. Torque the cap bolts to specifications.
3. Repeat the procedure for the remaining bearings that require replacement.
4. If the rear main bearing is replaced, replace the lower seal and side seals in the rear main bearing cap. Remove and discard the rear seal and side seals.
5. Preform the new seal by hand to the approximate radius of the cap. Insert the seal in the oil seal groove, seating the center of the oil seal first and allowing the seal to extend equally on both ends. Press the seal down firmly with the thumb at the center of the seal, and then press both ends of the seal into the groove, working from the ends to the center.

Position the seal forming tool as shown in Fig. 28 and complete the seal installation. After installation, cut the ends of the seal 0.015 inch above the cap mounting surface.

6. Apply a thin coating of oil-resistant sealer to the rear main bearing cap at the rear of the top mating surface. **Do not apply sealer to the area forward of the side seal groove. Sealer should be applied up to but not past the side seal.** Install the rear main bearing cap. Torque the main bearing cap bolts to specifications.
7. Dip the side seals in light engine oil, then immediately install them in the grooves. **Do not use sealer on the side seals. The seals are designed to expand when dipped in oil. Using sealer may retard this expansion.** It may be necessary to tap the seals into place for the last 1/2 inch of travel. Do not cut the seal projecting ends.
8. Check the side seals for leaks by squirting a few drops of oil into the parting lines between the retainer and the cylinder block from the outside. Blow compressed air against the seals from the inside of the block. If air bubbles appear in the oil, it indicates possible oil leakage. **This test should not be performed on newly installed seals until sufficient time has been allowed for the seals to expand into the grooves.**
9. If the thrust bearing (No. 3) is replaced, install the thrust bearing cap with the bolts finger tight.
10. Pry the crankshaft forward against the thrust surface of the upper half of the bearing (Fig. 29).
11. Hold the crankshaft forward and pry the thrust bearing cap to the rear. This will align the thrust surfaces of both halves of the bearing.
12. Retain the forward pressure on the crankshaft. Torque the cap bolts to specifications.
13. Force the crankshaft toward the rear of the engine.

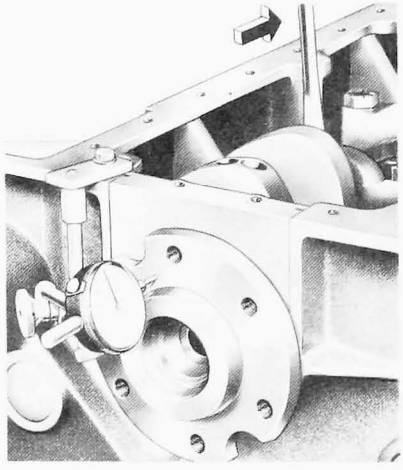

FIG. 30 Checking Crankshaft End Play

14. Install a dial indicator so the contact point rests against the crankshaft flange and the indicator axis is parallel to the crankshaft axis (Fig. 30).
15. Zero the dial indicator. Push the crankshaft forward and note the reading on the dial.

If the end play exceeds the wear limit, replace the thrust bearing. If the end play is less than the minimum limit, inspect the thrust bearing faces for scratches, burrs, nicks, or dirt. If the thrust faces are not damaged or dirty, they probably require alignment. Install the thrust bearing and align the faces following the recommended procedure (steps 19 thru 22) then check the end play.

16. Install the oil pan following the procedures under Oil Pan and Oil Pump Installation.

17. Fill the crankcase with the proper amount and viscosity oil.
18. Operate the engine and check for oil leaks.

CONNECTING ROD BEARINGS

Removal

1. Follow step 1 under Main Bearing Replacement.
2. Remove the cap from the connecting rod to which a new bearing is to be fitted.
3. Follow step 5 under Main Bearing Replacement.

Installation

1. Install the new bearings in the connecting rod and cap.
2. Pull the connecting rod assembly down firmly on the crankshaft journal.
3. After the bearings have been fitted as detailed in Part 21-01, apply a light coat of heavy engine oil to the journal and bearings, then install the connecting rod cap. Torque the nuts to specifications.
4. Repeat the procedure for the remaining connecting rods that require new bearings.

PISTONS AND CONNECTING RODS

Removal

1. Drain the cooling system and the crankcase. Remove the valve rocker arm shaft assemblies, intake manifold, cylinder heads, oil pan, and oil pump following the procedures in this section.
2. Turn the crankshaft until the piston to be removed is at the bottom of its travel. Place a cloth on the piston head to collect the cuttings. Remove any ridge and/or deposits from the upper end of the cylinder bore with Tool T64L-6011-EA or its equivalent. Follow the instructions furnished by the tool manufacturer. **Never cut into the ring travel area in excess of 1/32 inch when removing ridges.**
3. Make sure all connecting rod caps are marked so that they can be installed in their original locations.
4. Turn the crankshaft until the connecting rod being removed is down.
5. Remove the connecting rod cap.
6. Push the connecting rod and piston assembly out the top of the cylinder with the handle end of a hammer. **Avoid damaging the crankshaft journal or the cylinder wall with the connecting rod studs when removing the piston and connecting rod.**
7. Remove the bearing inserts from the connecting rod and cap.
8. Install the cap on the connecting rod from which it was removed.

Installation

1. If new piston rings are to be installed, remove the cylinder wall glaze (Part 21-01, Cylinder block). Follow the instructions of the tool manufacturer. After performing cylinder bore repairs clean the bore(s), following the procedure in Part 21-01.
2. Oil the piston rings, pistons, and cylinder walls with heavy engine oil before installation.

Be sure to install the pistons in the same cylinders from which they were removed, or to which they were fitted. The connecting rod and bearing caps are numbered from 1 to 4 in the right bank, and from 5 to 8 in the left bank, beginning at the front of the engine. The numbers on the connecting rod and bearing cap must be on the same side when installed in the cylinder bore. If a connecting rod is ever transposed from one block or cylinder to another, new bearings should be fitted, and the connecting rod should be numbered to correspond with the new cylinder number.

3. Make sure the ring gaps are properly spaced around the circumference on the piston (Fig. 31).
4. Install a piston ring compressor on the piston and push the piston in with a hammer handle until it is slightly below the top of the cylinder (Fig. 32). Be sure to guide the connecting rods to avoid damaging the crankshaft journals. **Install the piston with the step toward the inside of the engine V.**
5. Check the clearance of each bearing following the procedure in Part 21-01, Fitting Bearings with Plastigage.
6. After the bearings have been fitted, apply a light coat of engine oil to the journal and bearings.
7. Turn the crankshaft throw to the bottom of its stroke; then push the piston all the way down until the rod bearing seats on the crankshaft journal.
8. Install the connecting rod cap. Torque the nuts to specifications.
9. After the piston and connnecting rod assemblies have been installed, check the side clearance between the connecting rods on each connecting rod crankshaft journal (Fig. 33).
10. Clean the oil pump inlet tube screen and the oil pan and block gasket surface. Prime the oil pump and install the pump, oil pan, cylinder heads, valve rocker arm shaft assemblies, and intake manifold following the procedures in this section.
11. Open the air bleed valve at the front of the intake manifold and fill and bleed the cooling system. Close the air bleed valve when the coolant comes out. Fill the crankcase with the proper amount and viscosity oil.
12. Operate the engine and check for oil and coolant leaks. Perform a final (hot) valve clearance adjustment. Adjust the engine idle speed and fuel mixture. Install the valve rocker arm covers. Install the air cleaner.

CRANKSHAFT

The crankshaft and related parts are shown in Fig. 34.

Removal

1. Remove the alternator adjusting arm attaching bolt and spacer from the cylinder front cover. Loosen the alternator mounting bolts and pivot the alternator toward the engine and remove the drive belts.
2. Remove the power steering pump and drive belts.

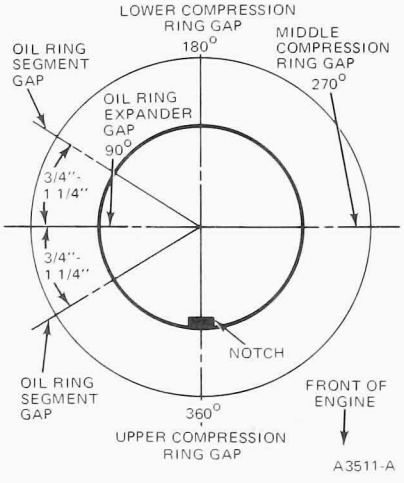

FIG. 31 Piston Ring Gap Spacing

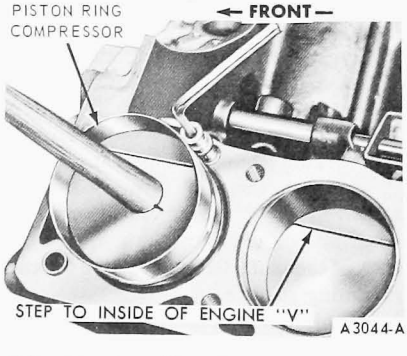

FIG. 32 Installing Piston

3. Remove the air compressor idler pulley and drive belt.
4. Remove the crankshaft damper attaching nut, then remove the crankshaft damper (Fig. 19).
5. Remove the key from the crankshaft. Remove the cylinder front cover.
6. Remove the oil slinger. If it is necessary to remove the crankshaft gear, remove the gear at this time with the tool shown in Fig. 16.
7. Invert the engine on the workstand. Remove the clutch pressure plate and disc. Remove the flywheel. Remove the oil pan and gasket. Remove the oil pump.
8. **Make sure all bearing caps (main and connecting rod) are marked so that they can be installed in the original locations.** Remove the connecting rod bearing caps. Turn the crankshaft until the connecting rod from which the cap is being removed is at the bottom of its stroke. After the cap is removed, push the connecting rod and piston assembly up in the cylinder.
9. Remove the main bearing caps.
10. Carefully lift the crankshaft out of the block so that the thrust bearing surfaces are not damaged. **Handle the crankshaft with care to avoid damage to the finish surfaces.**

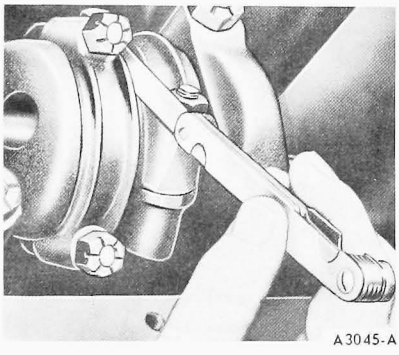

FIG. 33 Checking Connecting Rod Side Clearance

Installation

1. Remove the rear journal oil seal from the block and rear main bearing cap. Remove the side seals.
2. Remove the main bearing inserts from the block and bearing caps.
3. Remove the connecting rod bearing inserts from the connecting rods and caps.
4. Clean the rear journal oil seal groove and the mating surfaces of the block and rear main bearing cap. Preform the new seal by hand to the approximate radius of the cap.

Insert the seal in the oil seal groove, seating the center of the seal first and allowing the seal to extend equally on both ends. Press the seal down firmly with the thumb at the center of the seal, and then press both ends of the seal into the groove, working from the ends to the center. Position the seal forming tool as shown in Fig. 28 and complete the seal installation. After installation, cut the ends of the seals 0.015 inch above the cap mounting surface.

This prevents rough edges which may project from the groove and lodge between the bearing cap and cylinder block.

5. If the crankshaft main bearing journals have been refinished to a definite undersize, install the correct undersize bearings. Be sure the bearing inserts and bearing bores are clean. Foreign material under the inserts will distort the bearing and cause a failure.
6. Place the upper main bearing inserts in position in the bores with the tang fitting in the slot provided.
7. Install the lower main bearing inserts in the bearing caps.
8. Carefully lower the crankshaft into place. **Be careful not to damage the bearing surfaces.** Align the timing mark on the crankshaft gear with the mark on the camshaft gear as the gears are meshed.
9. Check the clearances of each main bearing as detailed in Part 21-01.
10. After the bearings have been fitted, apply a coat of heavy engine oil to the journals and bearings. Install all the bearing caps, except the thrust bearing cap (No. 3 bearing). **Be sure that the main bearing caps are installed in the original locations. Torque the bearing cap bolts to specifications.**
11. Install the thrust bearing cap with the bolts finger tight.
12. Pry the crankshaft forward against the thrust surface of the upper half of the bearing (Fig. 32).

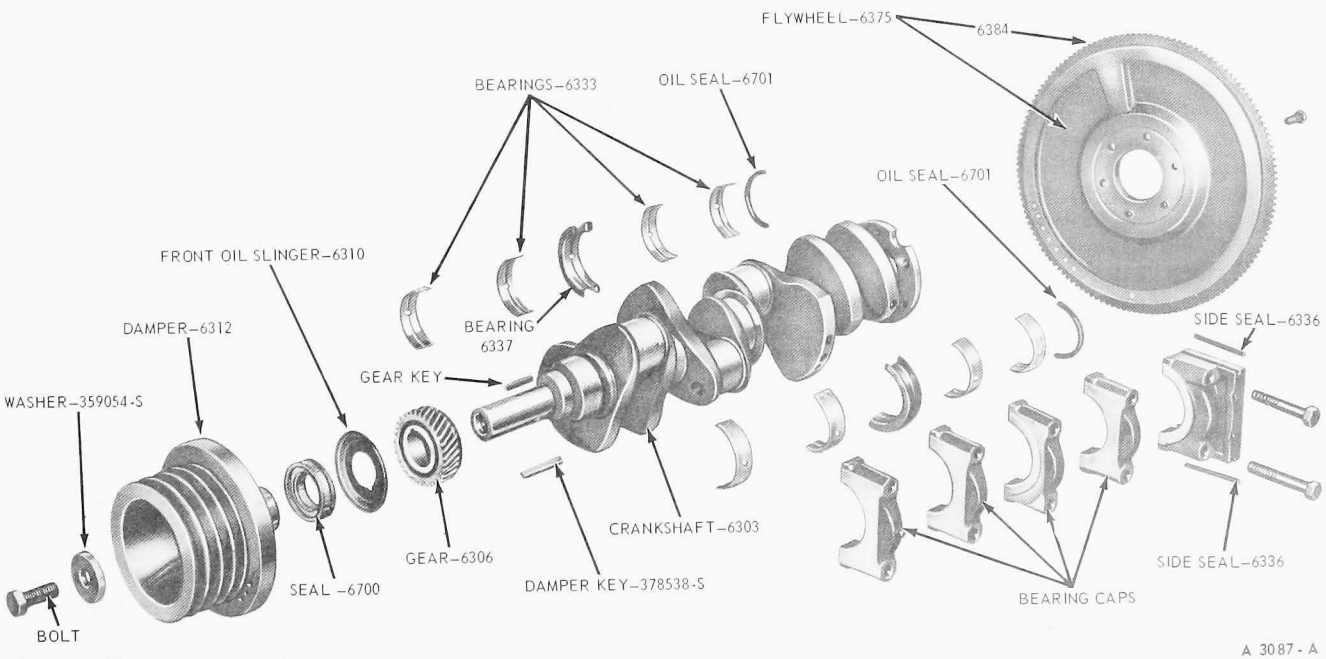

FIG. 34 Crankshaft Assembly

13. Hold the crankshaft forward and pry the thrust bearing cap to the rear. This will align the thrust surfaces of both halves of the bearing.
14. Retain the forward pressure on the crankshaft. Torque the cap bolts to specifications.
15. Force the crankshaft toward the rear of the engine.
16. Install a dial indicator so the contact point rests against the crankshaft flange and the indicator axis is parallel to the crankshaft axis (Fig. 30).
17. Zero the dial indicator. Push the crankshaft forward and note the reading on the dial.

If the end play exceeds the wear limit, replace the thrust bearing. If the end play is less than the minimum limit, inspect the thrust bearing faces for scratches, burrs, nicks, or dirt. If the thrust faces are not damaged or dirty, they probably need alignment. Install the thrust bearing and align the faces following the recommended procedure (steps 11 thru 14), then check the end play.

18. Install the rear main bearing cap oil seal and side seals; then check the seals for leaks by following steps 16 thru 19 under Main Bearing Replacement.
19. Turn the crankshaft throw to the bottom of its stroke. Push the piston all the way down until the rod bearing seats on the crankshaft journal.
20. Install new bearing inserts in the connecting rods and caps. Check the clearance of each bearing following the procedure under Connecting Rod Bearing Replacement.
21. After the bearings have been fitted, apply a light coat of engine oil to the journals and bearings.
22. Install the connecting rod cap. Torque the nuts to specifications.
23. After the piston and connecting rod assemblies have been installed, check the side clearance between the connecting rods on each connecting rod crankshaft journal (Fig. 33).
24. Clean the oil pan, oil pump, and oil pump screen.
25. Position the flywheel on the crankshaft. Install the attaching bolts. Torque the bolts to specifications.

Use Tool 7653 to center the clutch disc. Install the pressure plate.

If the crankshaft gear was removed, install it on the crankshaft with the tool shown in Fig. 22 with timing marks on the camshaft gear and crankshaft gear in alignment (Fig. 20).

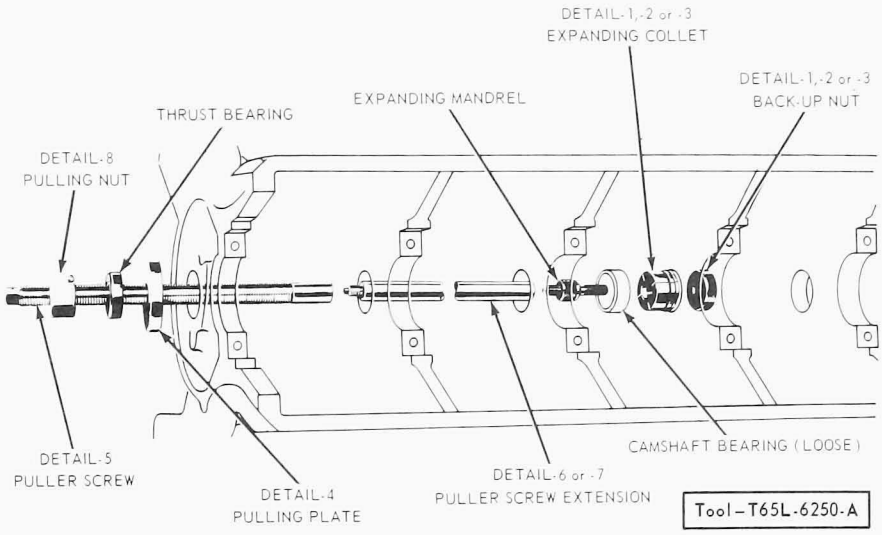

FIG. 35 Replacing Camshaft Bearing

26. Install the oil slinger. Install the cylinder front cover and related parts and the crankshaft damper following the procedure under Cylinder Front Cover and Timing Gears Installation.
27. Prime the oil pump and install the oil pump and the oil pan.
28. Install the air compressor idler pulley and drive belt. Adjust the drive belt tension. Position the alternator adjusting arm and spacer on the cylinder front cover. Install the drive belt and adjust the tension. Tighten the alternator attaching bolts.

CAMSHAFT BEARINGS

Camshaft bearings are available prefinished to size for standard and 0.015 inch undersize journal diameters. The No. 1 camshaft bearing is not interchangeable with the other bearings.

Removal

1. Remove the flywheel, crankshaft and camshaft.
2. Push the pistons to the top of the cylinders to move the connecting rods out of the way.
3. Remove the camshaft rear bearing bore plug.
4. Remove the camshaft bearings.

If the camshaft bearings are being removed with the tool shown in Fig. 35 the following procedure will apply. Select the proper size expanding collet and back-up nut and assemble on the expanding mandrel. With the expanding collet collapsed, install the collet assembly in the camshaft bearing, and tighten the back-up nut on the expanding mandrel until the collet fits the camshaft bearing. Assemble the puller screw and extension (if necessary) as shown and install on the expanding mandrel. Tighten the pulling nut against the thrust bearing and pulling plate to remove the camshaft bearing. Be sure to hold a wrench on the end of the puller screw to prevent it from turning. Repeat the procedure for each bearing. To remove the front bearing, install the

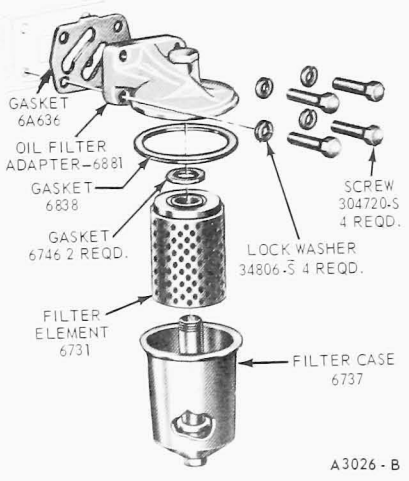

FIG. 36 Oil Filter Assembly

puller screw from the rear of the cylinder block.

Installation

1. Position the new bearing at the bearing bores, and press them in place with the tool shown in Fig. 35. Be sure to center the pulling plate and the puller screw to avoid damage to the bearing. Wrap a cloth around the threads of the puller screw to protect the front bearing or journal. **Failure to use the correct expanding collet can cause severe bearing damage.** Align the oil holes in the bearings with the oil holes in the cylinder block when the bearings are installed. Particular care should be taken with the No. 2 and 4 bearings because they supply oil to the valve rocker arms. Be sure the front bearing is installed below the front face of the cylinder block to specifications.
2. Install the camshaft rear bearing bore plug as detailed in Part 21-01.
3. Clean and install the camshaft, crankshaft, flywheel, and related parts. Install the engine in the vehicle.

OIL FILTER

The oil filter assembly is shown in Fig. 36.

Removal

1. Place a drip pan under the filter. Remove the filter center bolt, then remove the filter assembly and gasket.
2. Remove the filter element, neoprene gasket, spring and retainer.
3. Remove the center bolt from the container and the fiber gasket from the bolt. Discard the filter element.
4. Wash all parts in solvent. Make sure all the openings in the center bolt are clean.

Installation

1. Install the new filter element in the housing following the instructions furnished with the new element.
2. Clean the filter adapter recess, then install a new gasket. Place the filter assembly in position, and thread the center bolt into the adapter finger tight.
3. Rotate the filter assembly slightly, in each direction to make sure the gasket is seated evenly. Tighten the center bolt to specifications. **Do not overtighten the center bolt.**
4. Add oil to the crankcase as necessary; then operate the engine at fast idle, and check for leaks.

DISASSEMBLY AND ASSEMBLY

When installing nuts or bolts (refer to the torque specifications at end of this Part), oil the threads with light weight engine oil. **Do not oil threads that require oil-resistant or water-resistant sealer.**

ENGINE

Disassembly

1. Remove the distributor cap and spark plug wires as an assembly.
2. Remove the cooling system air vent lines.
3. Remove the coil.
4. Disconnect the governor control rod at the governor.
5. Remove the carburetor fuel inlet line. Remove the crankcase ventilation regulator valve and exhaust tube.
6. Slide the clamp on the intake manifold coolant outlet hose toward the water pump.
7. Remove the intake manifold attaching bolts; then remove the intake manifold.
8. Remove the intake manifold coolant outlet hose elbow and gasket from the intake manifold and remove the front thermostat.
9. Remove the rear thermostat housing cover and gasket; then remove the rear thermostat.
10. Remove the distributor.
11. Remove the governor.
12. Remove the valve push rod cover attaching screws, then remove the cover. Discard the cover gasket.
13. Remove the spring tension on the valve rocker arms by loosening the adjusting screws.
14. Remove the valve rocker arm shaft assembly and the oil baffle plate.
15. Remove the valve push rods in sequence (Fig. 14).
16. Install standard eye bolts with 5/8-18 threads in the cylinder head and attach the engine lifting sling (Fig. 15).
17. Remove the remaining cylinder head bolts. Raise the cylinder head and carefully remove it from the engine.
18. Place the cylinder head on a work bench and remove the exhaust manifold and heat shield, then install the holding fixtures. The flat washers can be reused.
19. Loosen the oil filter center bolt; then remove the filter assembly and gasket.
20. Remove the oil filter adapter and discard the gasket.
21. Remove the oil cooler cover, gasket, oil cooler, and gasket.
22. Remove the relief valve plug and gasket; then remove the spring and plunger.
23. Invert the engine on the work stand.
24. Remove the oil pan. Discard the gasket.
25. Remove the oil pump. Discard the gasket. Remove the intermediate drive shaft from the engine.
26. Remove the clutch from the flywheel.
27. Remove the flywheel.
28. Remove the drive belts.
29. Remove the damper capscrew and washer. Install the removal tool and remove the damper (Fig. 19).
30. Remove the alternator and adjusting arm as an assembly.
31. Remove the air compressor.
32. Remove the water pump and housing as an assembly and the engine front support bracket.
33. Remove the cylinder front cover. Discard the gasket.
34. Remove the valve tappets keeping them in order so that they can be installed in their original position (Fig. 18).
35. Remove the camshaft gear, spacer, thrust plate and camshaft as an assembly (Fig. 25).
36. Remove the crankshaft front oil slinger.
37. Remove the crankshaft gear (Fig. 21).
38. Turn the engine on the workstand so that the front is up.
39. Remove any ridge and/or deposits from the upper end of the cylinder bores with Tool T64L-6011-EA, or equivalent. Turn the crankshaft until the piston to be removed is at the bottom of its travel. Place a cloth on the piston heads to collect the cuttings. Remove any ridge and/or deposits from the upper end of the cylinder bore. Remove the cylinder ridge with a ridge cutter. Follow the instructions furnished by the tool manufacturer. **Never cut into the ring travel area in excess of 1/32 inch when removing ridges.**
40. Make sure all bearing caps (main and connecting rod) are marked so

that they can be installed in the original locations.

41. Turn the crankshaft until the connecting rod being removed is down.
42. Remove the nuts from the connecting rod bolts, then pull the cap off the rod.
43. Push the connecting rod and piston assembly out the top of the cylinder with the handle end of a hammer. **Avoid damage to the crankshaft journal or the cylinder wall when removing the pistons and rod.**
44. Remove the bearing inserts from the connecting rod and caps.
45. Remove the main bearing caps.
46. Carefully lift the crankshaft out of the cylinder block so that the thrust bearing surfaces are not damaged. **Handle the crankshaft with care to avoid possible damage to the finished surfaces.**
47. Remove the rear journal oil seal from the block and rear main bearing cap. Remove the rear bearing cap to block side seals.
48. Drill a 1/2 inch hole in the crankshaft rear bearing bore plug and use Tools T59L-100-B and T58-L-101-A to remove the plug.
49. Remove the camshaft bearings (Fig. 35).

Assembly

Many of the procedures given here are condensed from other sections of this group. For more detailed steps, refer to the index at the beginning of this part or Part 21-01. These indexes will show the pages on which more detailed instructions can be found.

1. Position the new camshaft bearing at the bearing bore, and align the oil holes in the bearings with the oil holes in the cylinder block. Press each bearing into place as shown in Fig. 35. **Be sure the camshaft front bearing is installed below the front face of the cylinder block to specifications.**
2. Check the oil passage that feeds the rocker arm shafts for obstructions by squirting oil into the opening on each cylinder bank and observing the flow through the oil holes at No. 4 camshaft bearing for the left bank and No. 2 camshaft bearing for the right bank.
3. Install a new camshaft rear bearing bore plug as detailed in Part 21-01.
4. If a new camshaft is to be installed, remove the gear, spacer, and thrust plate from the old camshaft and install them on the new camshaft, then install the camshaft.
5. Apply heavy oil on the camshaft bearing journals, camshaft gear and bearings. Apply Lubriplate or equivalent to all camshaft lobes. Carefully slide it through the bearings with the gear, spacer, and thrust plate attached (Fig. 25). Be sure the camshaft is installed so that the timing mark on the camshaft gear is aligned with the center of the crankshaft front bearing bore.
6. Install the thrust plate attaching bolts and tighten them to specifications. Check camshaft end play.
7. Be sure that the rear journal oil seal grooves are clean. Install a new rear journal oil seal in the block. Preform the new seal by hand to the approximate radius of the cap.

Insert the seal in the oil seal groove, seating the center of the seal first and allowing the seal to extend equally on both ends. Press the seal down firmly with the thumb at the center of the seal, and then press both ends of the seal into the groove, working from the ends to the center. Position the seal forming tool as shown in Fig. 28 and complete the seal installation. After installation, cut the ends of the seal 0.015 inch above the cap mounting surface.

8. If the crankshaft main bearing journals have been refinished to a definite undersize, install the correct undersize bearings. Be sure the bearing inserts and bearing bores are clean.

Place the upper main bearing inserts in position in the bores with the tang fitting in the slot provided.

10. Carefully lower the crankshaft into place so that the timing mark on the gear is aligned with the timing mark on the camshaft gear (Fig. 20). **Be careful not to damage the bearing surfaces.**
11. Check the clearance of each main bearing following the procedure in Part 21-01 Fitting Bearings with Plastigage.
12. After the bearings have been fitted, apply a light coat of heavy engine oil to the journals and bearings, then install all the bearing caps except the thrust bearing cap (No. 3 bearing). Install the rear main bearing cap oil seal and side seals, then check the side seals for leaks by following steps 16 thru 19 under Main Bearing Replacement. Torque the bearing cap bolts to specifications.
13. Install the thrust bearing cap and check crankshaft end play by following steps 11 thru 17 under Crankshaft Installation. Check the camshaft gear backlash (Part 21-01).
14. Turn the engine on the workstand so that the front end is up.
15. Install the pistons and connecting rods by following steps 1 thru 8 under Piston and Connecting Rod Installation.
16. Clean the cylinder front cover, water pump, and the cylinder block gasket surfaces. Install a new front oil seal.
17. Coat the gasket surface of the cover and block and the cover bolt threads with sealer.
18. Position a new gasket on the block; then install the cylinder front cover.
19. Install the engine front support bracket. Clean, inspect and polish the oil seal rubbing surface on the crankshaft damper hub (Part 21-01). Install the crankshaft damper (Fig. 23).
20. Refer to Fig. 11 for the oil cooler assembly. Install the relief valve plunger (with the open end up), spring, gasket and plug in the cover. Place a new oil cooler gasket with sealer on both sides on the block. Position the oil cooler in the block. Place a new gasket on the cover with sealer on both sides of the gasket. Install the cover. Tighten the cover bolts to specifications.
21. Apply water-resistant sealer to the water pump housing gaskets and position them on the block. Install the water pump and housing assembly.
22. Install the alternator.
23. Install the air compressor. Install the air compressor idler arm pulley on the cylinder front cover.
24. Install and adjust the drive belts. Install the fan.
25. Invert the engine on the workstand.
26. Insert the oil pump drive shaft into the oil pump.
27. Position a new gasket on the oil pump housing, prime the pump, and install the oil pump, shaft, and pick-up tube as an assembly (Fig. 27). Tighten the oil pump attaching screws to specifications.
28. Remove old gasket sealer from the oil pan and block gasket surfaces.
29. Position a new gasket on the oil pan. Hold the oil pan in place against the cylinder block and install two of the attaching screws on each side of the pan. Install the remaining screws and tighten them from the center outward to specifications.
30. Position the flywheel on the crankshaft and install the attaching bolts. Tighten the bolts to specifications.
31. Install the clutch on the flywheel.
32. Clean the oil filter adapter gasket surfaces. Apply oil-resistant sealer to a new adapter gasket, and install the adapter assembly and gasket.

Install the oil filter assembly following the procedure under Oil Filter Replacement.

33. Clean the old gasket from the cylinder head and block gasket surfaces. Coat the threads of the cylinder head bolts with engine oil.
34. Remove the cylinder head holding fixtures.
35. Install the gaskets and the exhaust manifolds and the spark plugs.
36. Install standard eye bolts with 5/8-18 threads in the cylinder head and attach the engine lifting sling.
37. Guided by the word TOP on the gasket, install the gasket over the cylinder head dowels. **Gasket sealer must not be used on the cylinder head gasket.**
38. Position the cylinder head on the engine (Fig. 15). Slide the flat washers on the cylinder head bolts. Install the five outside bolts with the flat washers but do not tighten. Remove the lifting sling and eye bolts.
39. Dip the tappet foot in Lubriplate or equivalent. Coat the remainder of each tappet and tappet bore with heavy engine oil. Install the tappets in their original bore.
40. Apply Lubriplate or equivalent to both ends of the push rods. Install the push rods in their proper sequence, making sure the lower ends are positioned in the tappet socket.
41. Position the oil baffle plate and the valve rocker arm shaft assembly on the cylinder head.
42. Install the remaining five cylinder head bolts and flat washers but do not tighten.
43. The cylinder head bolt tightening procedure is performed in three progressive steps. Follow the sequence shown in Fig. 16. Tighten the bolts to specifications. When the cylinder head bolts have been tightened as detailed in this procedure, it is not necessary to retorque them after extended operation.
44. Perform a preliminary valve clearance adjustment (Part 21-01). The final valve clearance adjustment is made with the engine installed in the vehicle.
45. Coat one side of the valve push rod cover gasket with oil-resistant sealer. Lay the cemented side of the gasket in place on the block and cylinder head. Install the cover by following step 11 under Cylinder Head Installation.
46. Using a new gasket, position the governor assembly on the cylinder block and install the washers and attaching nuts.
47. Crank the engine until No. 1 piston is on TDC at the end of the compression stroke.
48. Inspect the distributor 0-ring seal and replace it if it is damaged. Position the distributor in the block with the rotor at the No. 1 firing position and the breaker points just start to open. Install the hold down clamp.
49. Clean the intake manifold gasket surfaces (including the front and rear thermostat housing gasket surface if the thermostats were removed).
50. If the thermostats were removed, position them in their respective housing. **Be sure the lower temperature thermostat is installed in the rear of the manifold and the higher temperature thermostat is installed in the front of the manifold.** Apply water-resistant sealer to the thermostat housing gaskets and position them on the intake manifold. Install the intake manifold coolant outlet elbow and the rear thermostat housing cover.
51. Apply oil-resistant sealer to the intake manifold gaskets and position them on the cylinder heads.
52. Position the intake manifold assembly on the cylinder heads. Install the intake manifold bolts and lock washers; then tighten the bolts to specifications.

Install the crankcase ventilation valve and tube.

53. Install the cooling system air vent lines, the distributor cap and spark plug wire assembly. Install the coil. Connect and adjust the governor linkage.
54. Clean the valve rocker arm cover(s). Apply oil-resistant sealer to one side of new cover gasket(s). Lay the cemented side of the gasket(s) in place in the cover(s).
55. Position the cover(s) on the cylinder head(s). Make sure the gasket seats evenly all around the head. Install the bolts (and the wire harness clamps on the left cover). The cover is tightened in two steps. Torque the bolts to specifications. Two minutes later, torque the bolts to the same specifications.

VALVE ROCKER ARM

Disassembly

1. Remove the cotter pins from each end of the valve rocker arm shaft.
2. Slide the rocker arms, springs, and the supports off the shaft. Be sure to identify all parts.
3. If it is necessary to remove the plugs from each end of the shaft, drill or pierce one plug; then insert a steel rod through the drilled plug and knock out the plug on the opposite end. Working from the open end, knock out the remaining plug.

Assembly

1. Lubricate all valve parts with heavy engine oil. Apply Lubriplate or equivalent to the pad of the valve rocker arms.
2. If the plugs were removed from the ends of the shaft, use a blunt tool, or large diameter pin punch and install a plug, cup side out, in each end of the valve rocker arm shaft.
3. Install a cotter pin in one end of the shaft; then install the rocker arms, supports, and springs in the order shown in Fig. 37. Complete the assembly by installing a cotter pin in the end of the shaft.

CYLINDER HEAD

Disassembly

The cylinder head assemblies are interchangeable from one side of the block to the other, provided the coolant air vent line plate is installed at the front of each cylinder head.

1. Install the cylinder head holding fixtures. Remove the deposits from the cylinder head and valve heads with a scraper and a wire brush before removing the valves. **Be careful not to scratch the cylinder head gasket surface.**
2. Compress the valve springs (Fig. 38), then remove the spring retainer lock, and release the spring.
3. Remove the spring retainer, spring, stem seal, and valve. Discard the valve stem seals. Identify all valve parts.

Assembly

1. Lubricate the valve guides and valve stems with heavy engine oil. Apply Lubriplate or equivalent to the tip of the valve stems.
2. Install each valve (Fig. 39) in the valve guide from which it was removed or to which it was fitted.
3. Install a new stem seal on the valve.
4. Position the valve spring over the valve, then install the spring retainer.
5. Compress the spring and install the retainer lock (Fig. 38).
6. Measure the assembled height of the valve spring from the surface of the cylinder head spring pad to the underside of the spring retainer with a scale (Fig. 40).

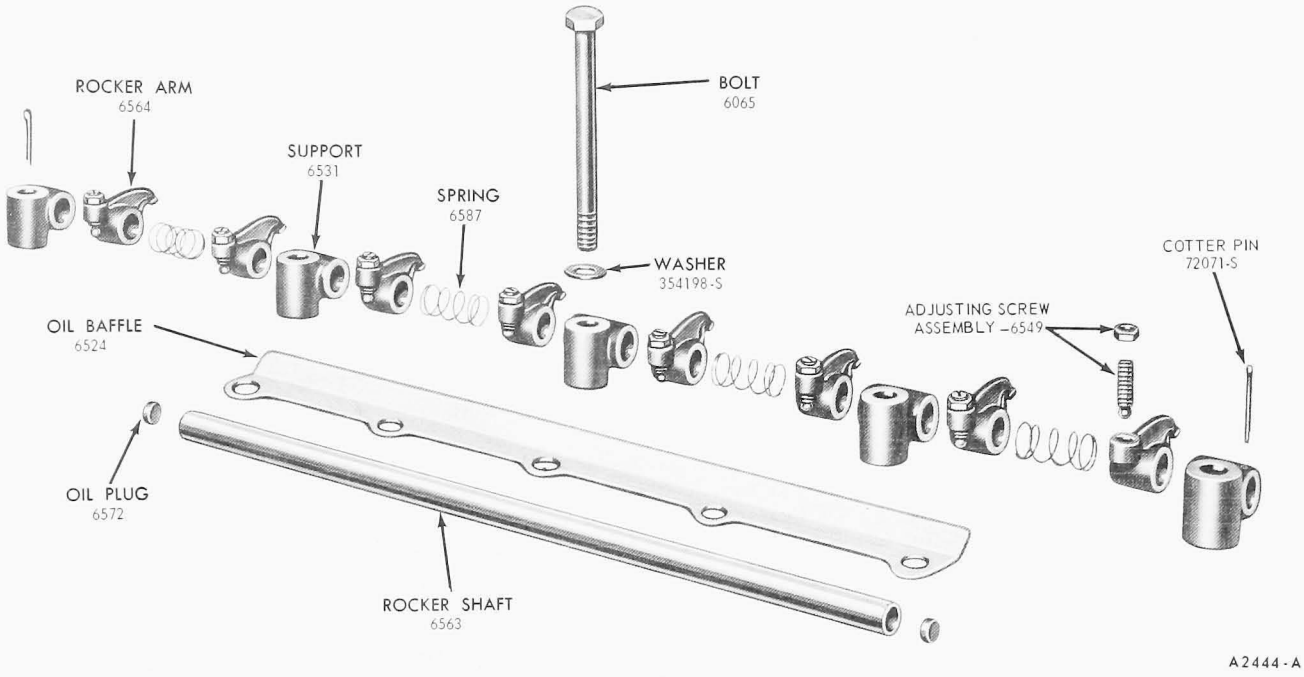

FIG. 37 Valve Rocker Arm Shaft Assembly

7. If the assembled height is greater than the specified height, install the necessary 0.030 inch thick spacer(s) between the cylinder head spring pad and the valve spring to bring the assembled height to within specified length. **Do not install spacers unless necessary. Use of spacers in excess of recommendations will result in overstressing the valve springs and overloading the camshaft lobes which could lead to spring breakage and worn camshaft lobes.**

OIL PUMP

Disassembly

The oil pump assembly is shown in Fig. 41.

1. Remove the oil pick-up tube and screen assembly from the oil pump and discard the gasket.
2. Remove the oil screen retaining wire and remove the screen.
3. Remove the cover attaching bolts, then remove the cover.
4. Remove the inner rotor and shaft assembly, then remove the outer race.
5. Insert a self-threading sheet metal screw of the proper diameter into the oil pressure relief valve chamber plug and pull the plug out of the chamber. Remove the spring and plunger.

Assembly

1. Clean and oil all parts thoroughly.
2. Install the oil pressure relief valve plunger, spring, gasket, and new plug.
3. Install the outer race, and the inner rotor and shaft assembly (Fig. 41). **Be sure to assemble the outer race so the dimple identification on the race is on the same side as the dimple on the rotor. The inner rotor and shaft, and the outer race are serviced as an assembly. One part should not be replaced without replacing the other.**
4. Install the cover and tighten the cover attaching bolts to specifications.
5. Install the screen and retaining wire in the pick-up tube.
6. Position a new gasket and the oil pick-up tube on the oil pump and install the attaching bolts.
7. Prime the pump installing it on the engine by filling the inlet port with engine oil. Rotate the pump shaft to distribute the oil within the pump body.

PISTON AND CONNECTING ROD

Disassembly

1. Mark the pistons and pins to assure assembly with the same rod and installation in the same cylinder from which they were removed.
2. Remove the piston rings. Remove the piston pin retainers using retaining ring pliers. Drive the pin out of the piston and rod. Discard the retainers.

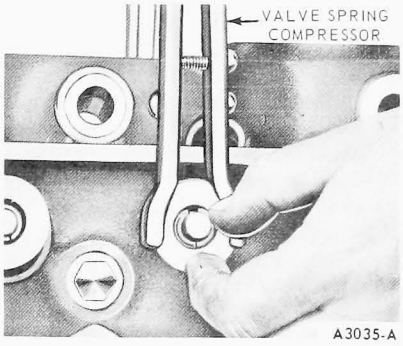

FIG. 38 Compressing Valve Spring

Assembly

The piston, connecting rod, and related parts are shown in Fig. 42.

1. Lubricate all parts with heavy engine oil prior to installation.
2. Position the connecting rod in the piston and push the pin into place. **Assemble the piston and connecting rod as shown in Fig. 43.**
3. Insert new piston pin retainers using retaining ring pliers.
4. Follow the instructions contained on the piston ring package and install the piston rings.
5. Check the ring side clearance of the compression rings with a feeler gauge inserted between the ring and its lower land (step 6 under Fitting Piston Rings).

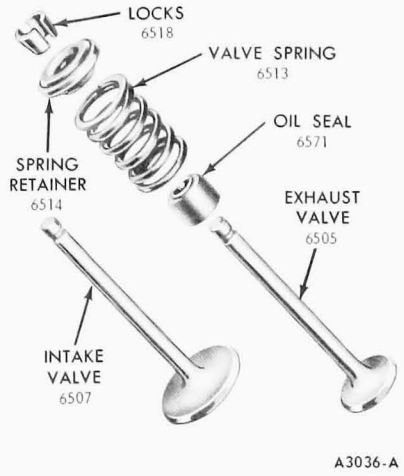

FIG. 39 Valve Assembly

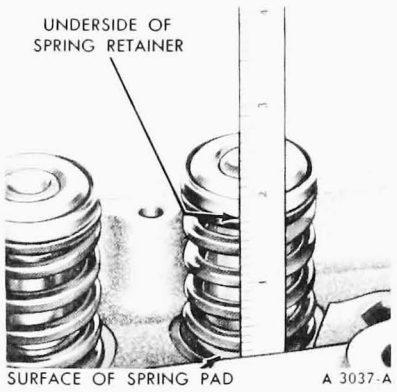

FIG. 40 Valve Spring Assembled Height

6. Be sure the bearing inserts and the bearing bore in the connecting rod and cap are clean. Foreign material under the inserts will distort the bearing and cause a failure. Install the bearing inserts in the connecting rod and cap with the tangs fitting in the slots provided.

GENERAL INFORMATION

This Group covers the adjustments, repairs and the Cleaning and Inspection recommendations for all Diesel engines used in FORD TRUCK VEHICLES. An engine code and application chart is shown in Fig. 1.

Refer to the Truck Diagnosis Manual to assist in resolving any problems that may occur.

Recommendations for periodic maintenance, maintenance instructions, including tests and adjustments, and lubrication charts, including lubricant specifications are contained in Volume 5 of the 1972 Ford Truck Shop Manual.

Refer to the applicable Diesel Shop Manual for complete adjustment, repair and overhaul procedures.

FIG. 1 Engine Identification

CLEANING AND INSPECTION

Strict adherence to thorough cleaning, accompanied by reliable inspections, are important factors in providing satisfactory Diesel engine operation.

When delays in completion of repairs or adjustments involve exposure of any openings into the engine or connected systems, close them off with a cover or fill the openings with clean, lint-free cloths until ready to resume work.

When inspection reveals for a definite series of checks or the complete or partial disassembly of a unit, specific instructions will be found in the applicable Diesel Engine Manual.

PART 22-03 Cummins Diesel Engines

Applies to L-,LT-,LTS-,LN-,LNT-,W- and WT-9000 Series

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ENGINE		ENGINE SUPPORTS	
Removal and Installation	03-01	Removal and Installation	03-01
		GENERAL INFORMATION	03-01

GENERAL INFORMATION

This part provides information for in-chassis service of Ford Diesel Trucks equipped with naturally aspirated Cummins Diesel engines. For service procedures on the turbo-charged NTC-335 and NTC-270-CT and -E custom torque Series Cummins engines, refer to the Cummins Engine Shop Manual.

Overhaul procedures, test stand procedures, specifications, and wear limits are covered in the Cummins engine Shop Manuals.

The four-stroke-cycle, Cummins Diesel engines have a compression ratio of 15.5:1. Overhead valves are push tube actuated by cam followers operated off the camshaft.

The PT (pressure-time) fuel pump is driven by the air compressor at engine speed. The engine speed governor is incorporated in the fuel pump. The tachometer is coupled to the fuel pump main shaft.

REMOVAL AND INSTALLATION

ENGINE SUPPORTS—L, LT, LTS, LN, LNT AND W-SERIES

ENGINE FRONT SUPPORT INSULATOR

Removal

1. On W-Series trucks, release the cab locks and tilt the cab forward.
2. Loosen the two engine support clamp bolts (Figs. 1 and 2).
3. Remove the two upper insulator attaching bolts.
4. Remove the two lower insulator attaching bolts and remove the insulator.
5. Place a wood block on a jack, then raise the engine high enough to remove the upper insulator and spacers.

Installation

1. Torque the engine support bracket-to-crossmember attaching bolts to specification.
2. Position a new upper insulator on the support bracket (Figs. 1 and 2).
3. Lower the engine enough to start the attaching bolts and washers in the spacers, then remove the jack.
4. Secure the lower insulator to the support bracket with the attaching bolts and washers. Torque the four insulator attaching bolts to specification.
5. Torque the two support clamp bolts to specification. **If the engine rear mounts were removed, do not torque the cap bolts until the engine rear supports are installed.**
6. On W-Series trucks, return the cab to its normal position and secure it with cab locks.

ENGINE REAR SUPPORT INSULATOR

Removal

1. On W-Series trucks, release the cab locks and tilt the cab forward.
2. Loosen the two engine front support clamp bolts (Figs. 1 and 2).
3. Remove the two capscrews from the engine rear support bracket and remove the cap.
4. Place a wood block on a jack and raise the rear of the engine just enough to remove the weight from the rear supports.
5. Remove the four bolts that attach the engine rear support to the frame side rail and remove the support and insulator.

Installation

1. Position a new insulator on the engine rear support (Figs. 1 and 2). Position the support and insulator to the frame side rail, install and torque the attaching bolts to specification.
2. Lower the engine and remove the jack.
3. Install and torque the cap screws in each engine rear support bracket and cap.
4. Torque the two engine front support clamp bolts to specification.
5. On W-Series trucks, return the cab to its normal position and secure it with the cab locks.

ENGINE

LN-SERIES

Removal

1. Remove the vehicle cab and engine hood assembly, following the procedures under Cab Removal.
2. Drain the engine crankcase and oil filters.
3. Disconnect the radiator upper and lower hoses at the engine. Disconnect the radiator shutter air line at the radiator. Remove the cooling fan and spacer.
4. Remove the radiator brace attaching

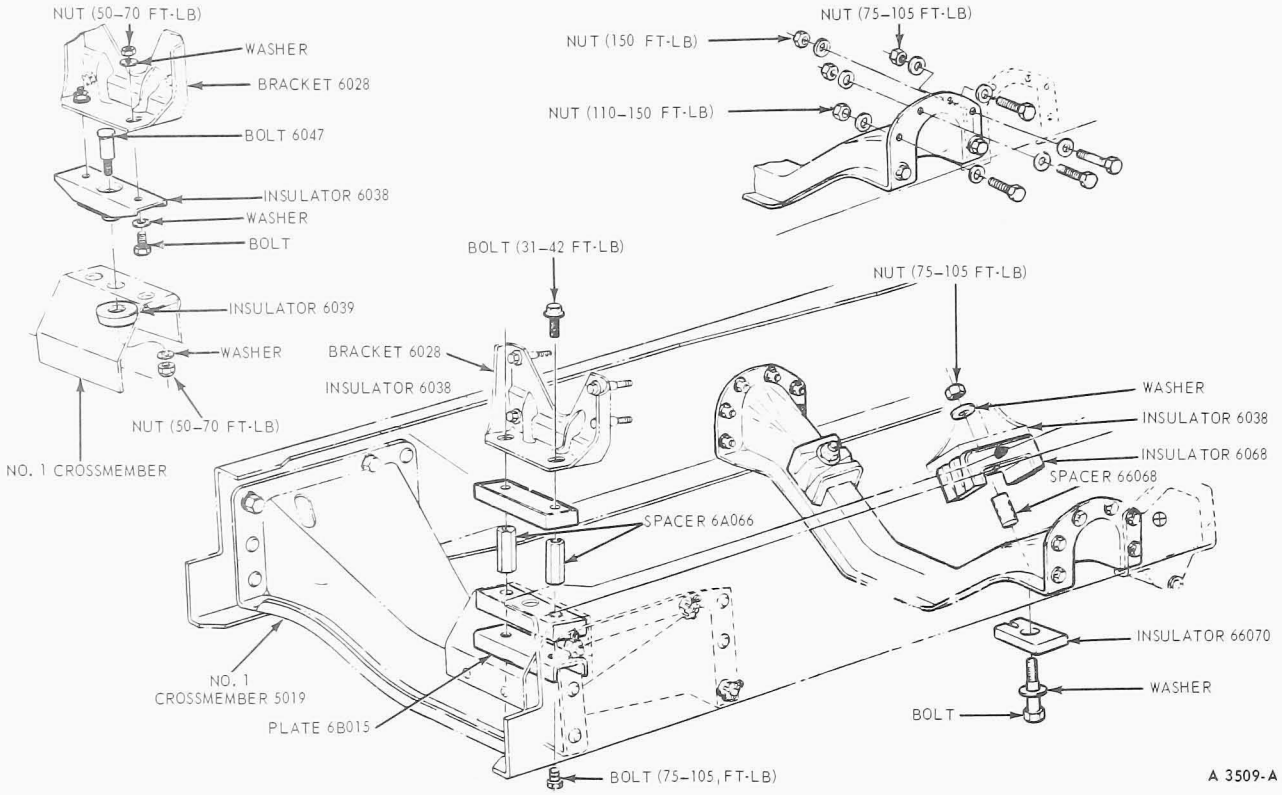

FIG. 1 Cummins Engine Supports L, LT, LN, LNT Series

nuts, washers and insulators at the radiator brackets. Remove the cooling fan and spacer. Remove the radiator support to frame mounting nuts, washers, insulator and springs. Use a hoist to lift the radiator, radiator support and shutter assembly off the vehicle.

5. Disconnect the oil filter lines from the Luber-Finer oil filter to the engine at the engine oil cooler and at the engine.
6. Loosen the power steering pump adjustment bolts, and disengage the drive belts. Remove the power steering pump to bracket mounting bolts, and position the pump out of the way on the left fender apron.
7. Disconnect the air reservoir supply line at the air compressor.
8. Remove the alternator wiring harness from the frame clips, and position it on the engine.
9. Disconnect the muffler inlet pipe from the exhaust manifold.
10. Disconnect the fuel return line from the rear cylinder head. Disconnect the fuel injection pump supply line at the fuel filter.
11. Disconnect the starter cables and identify them for proper connection.
12. Remove the clutch return spring and slave cylinder from the flywheel housing.
13. Remove the transmission.
14. Install the engine lifting brackets. Attach a hoist and the engine lifting fixture (Cummins ST-125) to the engine lifting brackets.
15. Remove the engine front support bracket cap (Figs. 1 and 2). Remove the engine rear support bolts, nuts and lower insulators. Carefully lift the engine out of the vehicle. Install the engine on a work stand or skid.

Installation

1. Check the crankshaft end clearance to be sure it is within specification. Then, install the engine lifting brackets, and attach a lifting fixture (Cummins ST-125) and hoist to the brackets. Remove the engine from the work stand or skid. Carefully position the engine in the vehicle and set it on the front support bracket and rear support insulators.
2. Install the engine rear supports. Install the engine front supports. Remove the hoist and lifting sling. Torque the engine front support bolts and the rear support nuts to specifications.
3. Remove the engine lifting brackets.
4. Install the transmission.
5. Install the clutch return spring and slave cylinder on the flywheel housing. Adjust the slave cylinder linkage.
6. Connect the starter cables to the same starter terminals from which they were removed.
7. Place a new gasket between the flanges of the muffler inlet pipe and exhaust manifold. Install the attaching bolts and nuts.
8. Connect the fuel injection pump supply line at the fuel filter. Connect the fuel return line to the rear cylinder head.
9. Place the alternator wiring harness in the frame clips.
10. Connect the air reservoir supply line to the air compressor.
11. Position the power steering pump on the pump bracket, and install the mounting bolts. Position the drive belts on the pulleys. Adjust the belt deflection to specifications.
12. Connect the oil filter lines at the oil cooler and at the engine.
13. Position the radiator support to frame insulator on the frame front crossmember. Use a hoist to lift the radiator, radiator support and shutter assembly onto the vehicle. Position the assembly on the radiator support insulator, and install the springs, washers and attaching nuts. Connect the radiator braces to the radiator support, and install the insulators and attaching nuts. Tighten the radiator brace and support nuts.
14. Use a new gasket and install the cooling fan and spacer. Check and adjust the cooling fan to fan shroud clearance; it should be uniform at 4 equidistant points.

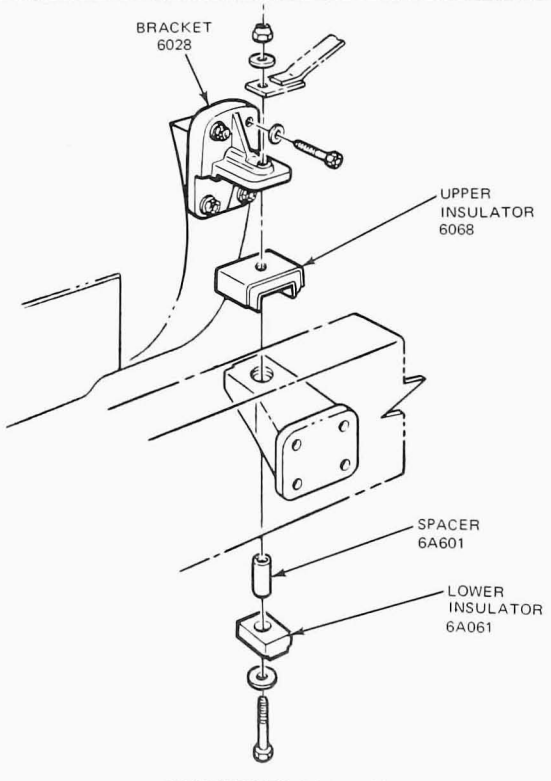
REAR SUPPORT



REAR SUPPORT INSULATOR
INSTALLATION (ALL ENGINES)

A3518-A

FIG. 2 Cummins Engine Supports—W-Series

15. Connect the radiator upper and lower hoses at the engine. Connect the radiator shutter air line at the radiator.
16. Install the truck cab and engine hood assembly, following the procedures under Cab Installation.
17. Fill the engine crankcase with the recommended lubricating oil. Fill and bleed the cooling system with the recommended coolant.
18. Start the engine and check for coolant, oil and fuel leaks. After operating the engine for a few minutes, stop it, and check the crankcase oil level. Add oil, as necessary, to bring the level up to the proper mark on the dipstick.

W-SERIES

The engine installation is shown in Figs. 3 and 4.

Removal

1. Release the cab locks and tilt the cab forward.
2. Drain the cooling system and the crankcase.
3. Disconnect the battery cables.
4. Remove the bolts and clamps and remove the air tubes from the air cleaner to the air manifold.
5. Disconnect the overflow and the by-pass hoses at the radiator.
6. Disconnect the upper and the lower radiator hoses at the engine.
7. Remove the fan assembly and spacer from the water pump.
8. Attach chain fall or crane, remove the attaching bolts and remove the radiator and shroud assembly.
9. Remove the power steering pump and bracket assembly and position it to one side.
10. Disconnect the heater hoses from the engine.
11. Remove the alternator and position it to one side.
12. Disconnect the ground wires from the cylinder block.
13. Disconnect the muffler inlet pipe from the exhaust manifold and discard the gasket.
14. Disconnect the throttle linkage from the fuel pump.
15. Remove button and bezel of the air starter control and position it to one side, if so equipped.
16. Disconnect the quick start cable from the fluid container.
17. Remove the shift lever knob and the two speed axle selector switch, and remove the tray from the shift lever support.
18. Disconnect the lead from the fuel shut down solenoid, and remove and position the wiring harness out of the way.
19. Disconnect the fuel line from the fuel filter.
20. Disconnect the fuel return line at the rear of the cylinder head.
21. Disconnect the starter air line at the tank, if equipped with air starter.
22. Disconnect and remove the temperature sending unit at the water manifold and the retainer at the cylinder block.
23. Remove the retaining clips and remove the oil temperature and the air pressure lines from the air compressor.
24. Remove the retainer and the air line and the air starter control lines at

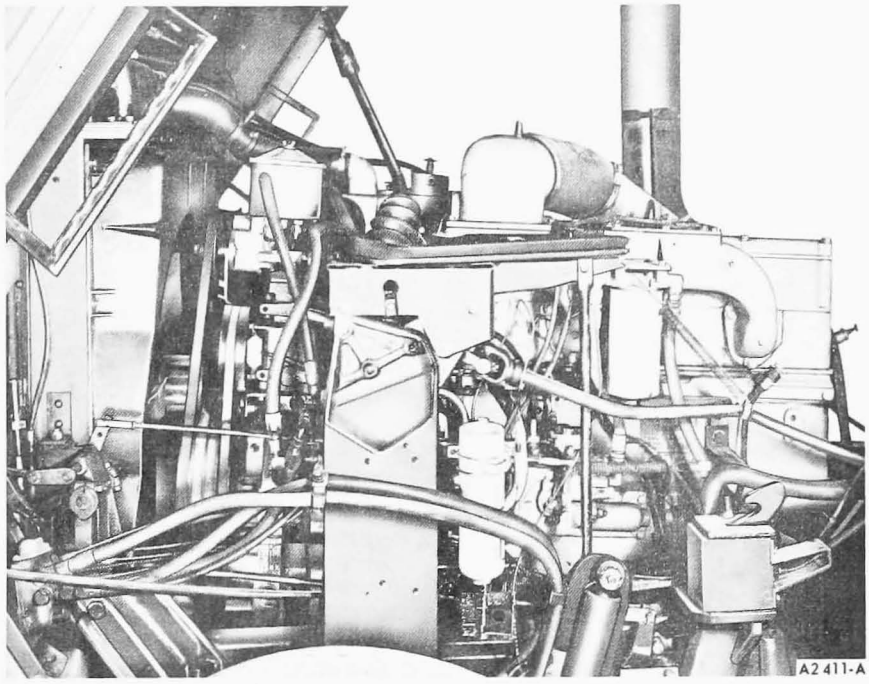


FIG. 3 W-Series Installation—Left View

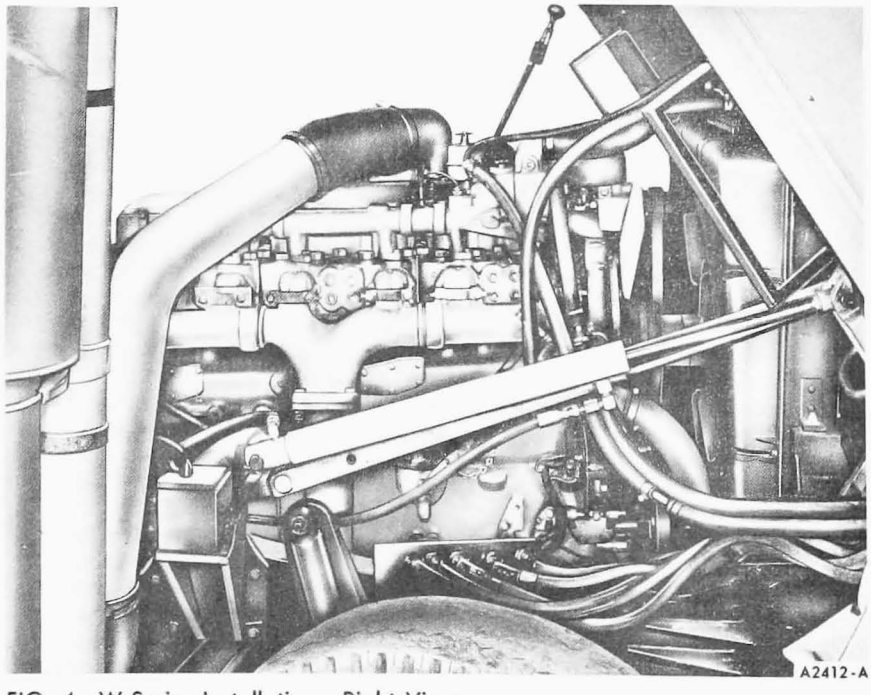

FIG. 4 W-Series Installation—Right View

the cylinder block, if so equipped.
25. Disconnect the oil pressure gauge line at the cylinder block.
26. Remove the oil temperature sending unit from the crankcase.
27. Disconnect the oil line (connected to the oil filter) at the crankcase.
28. Disconnect the oil line that connects the chassis mounted oil filter to the engine mounted oil filter, at the engine mounted oil filter.
29. Disconnect the tachometer cable at the fuel pump.
30. Disconnect the quick start line at the manifold.
31. Remove the air horn from the air manifold.
32. Disconnect the clutch linkage rods at the rear equalizer arm, remove the equalizer arm mounts and remove the equalizer arm.
33. Remove the nuts and bolts that attach the front engine support to the number one crossmember.
34. Remove the cap from the engine front support.
35. Support and raise the transmission slightly while attaching chain fall and taking up slack.
36. Remove transmission to clutch housing bolts.
37. Remove engine rear support nuts.
38. Some installations may require removing the left chassis support frame side rail. If so remove the bolts and slide it past the starter and lift it out.
39. Carefully lift engine, easing it forward, lifting out engine front support as this is done. Remove engine from the chassis.

Installation

1. Remove the inspection cover from the bottom of the transmission clutch housing.
2. Carefully ease the engine down to the chassis and to the transmission aligning the throw out bearing fork with the throw out bearing. Position the engine front support and install the bolts and nuts and torque to specifications.
3. Install the transmission to clutch housing bolts and torque to specifications.
4. If it was removed, install the left hand chassis support frame side rail.
5. Install the rear engine support nuts, and install the inspection cover to the bottom of the transmission clutch housing.
6. Install the cap to the front engine support.
7. Install the equalizer arm mounts and the equalizer arm, and connect the clutch linkage rods.
8. Install the air horn on the air manifold.
9. Connect the quick start line at the manifold.
10. Connect the tachometer cable at the fuel pump.
11. Connect the oil line to the engine mounted air filter.
12. Connect the oil filter line at the crankcase.
13. Install the oil temperature sending unit on the crankcase.
14. Connect the oil pressure gauge line at the cylinder block.
15. If so equipped, position the air line and the air starter control lines at the cylinder block and install the retainer and the attaching bolt.
16. Position the oil temperature and air pressure lines and install the retaining clip on the air compressor.
17. Connect the temperature sending unit at the water manifold and the retainer at the cylinder block.
18. If equipped with an air starter, connect the air line at the tank.
19. Connect the fuel return line at the rear of the cylinder head.
20. Connect the fuel line to the fuel filter.
21. Position the wiring harness, and connect the lead to fuel shut down solenoid on the fuel pump.
22. Install the tray on the shift lever support, the two speed axle selector switch, and the shift lever knob.
23. Connect the quick start cable to the fluid container.
24. If so equipped, install the button and bezel of the air starter control.
25. Connect the throttle linkage at the fuel pump.
26. Position the gasket and connect the muffler inlet pipe to the exhaust manifold.
27. Connect the ground wires to the cylinder block.
28. Install the alternator.
29. Connect the heater hoses.
30. Position the power steering pump and bracket assembly and install the attaching bolts.
31. Ease the radiator and shroud assembly down into position and install the attaching bolts.
32. Install the spacer and the fan assembly on the water pump.
33. Connect the upper and lower radiator hoses.
34. Connect the overflow and the by-pass hoses at the radiator.
35. Position the air tubes from the air cleaner to the intake manifold and install the clamps and the bolts.
36. Connect the battery cables.
37. Fill the crankcase with the proper grade and quantity of engine oil. Fill and bleed the cooling system.
38. Lower and lock the cab.
39. Operate the engine and check for fuel, oil, and coolant leaks.

All adjustment, removal, installation, and repair operations will be performed by authorized Detroit Diesel Engine Dealers and Ford Truck Dealers who are authorized to repair Detroit Diesel Engines.

Service operations on Ford-warranted parts attaching to the Detroit Diesel engines are the responsibility of Ford truck dealers, and procedures for these operations are included in this part.

DESCRIPTION

The 8V-71N and 6-71N Detroit Diesel Engines are a 2-stroke cycle having a 4 1/4 inch bore and a 5 inch stroke. The total piston displacement is 567.5 CID for the 8V-71N and 426 CID for the 6-71N. The compression ratio is 18.7:1 for both engines. The 6V-53N has 3.87 inch bore and a 4 1/2 inch stroke. The total piston displacement is 318.4.

The patent plate identification symbols for the engines are shown in the engine application chart.

ADJUSTMENTS

When installing nuts or bolts (refer to the end of this Group for torque specifications), oil the threads with light weight engine oil. **Do not oil threads that require oil-resistant or water-resistant sealer.**

ENGINE SUPPORTS

FRONT SUPPORT INSULATORS

Removal

1. On W-Series trucks, release the cab locks and tilt the cab forward.
2. Loosen the two engine support clamp bolts (Figs. 2 and 3).
3. Remove the two upper insulator attaching bolts (Fig. 1).
4. Remove the two lower insulator attaching bolts (Fig. 1) or through bolts (Figs. 2 and 3) and remove the plate and insulator.
5. Place a wood block on a jack, then raise the engine high enough to remove the upper insulator and spacers.

Installation

1. Torque the engine insulator bracket-to-crossmember attaching bolts to specification.
2. Position a new upper insulator on the insulator bracket (Figs. 1, 2 and 3).
3. Lower the engine enough to start the attaching bolts and washers in the spacers (Fig. 1) then remove the jack.
4. Secure the lower insulator to the insulator bracket with the plate and (Figs. 1, 2 and 3) attaching bolts and washers or through bolts. Torque the insulator attaching bolts to specification. Secure the through bolts with cotter pins.
5. Torque the two support clamp bolts (Fig. 2) to specification. **If the engine rear mounts were removed, do not torque the cap bolts until the engine rear supports are installed.**
6. On W-Series trucks, return the cab to its normal position and secure it with the cab locks.

REAR SUPPORT INSULATORS

Removal

1. On W-Series trucks, release the cab locks and tilt the cab forward.
2. Loosen the two engine front support clamp bolts (Fig. 2 working on a vehicle equipped with a 6-71N or 8V-71N engine).
3. Remove the two capscrews from the engine rear support bracket and remove the cap.
4. Place a wood block on a jack and raise the rear of the engine just enough to remove the weight from the rear supports.
5. Remove the bolts that attach the engine rear support to the frame side rail and remove the support and insulator.

Installation

1. Position a new insulator on the engine rear support (Figs. 1, 2 and 3). Position the support and insulator to the frame side rail.

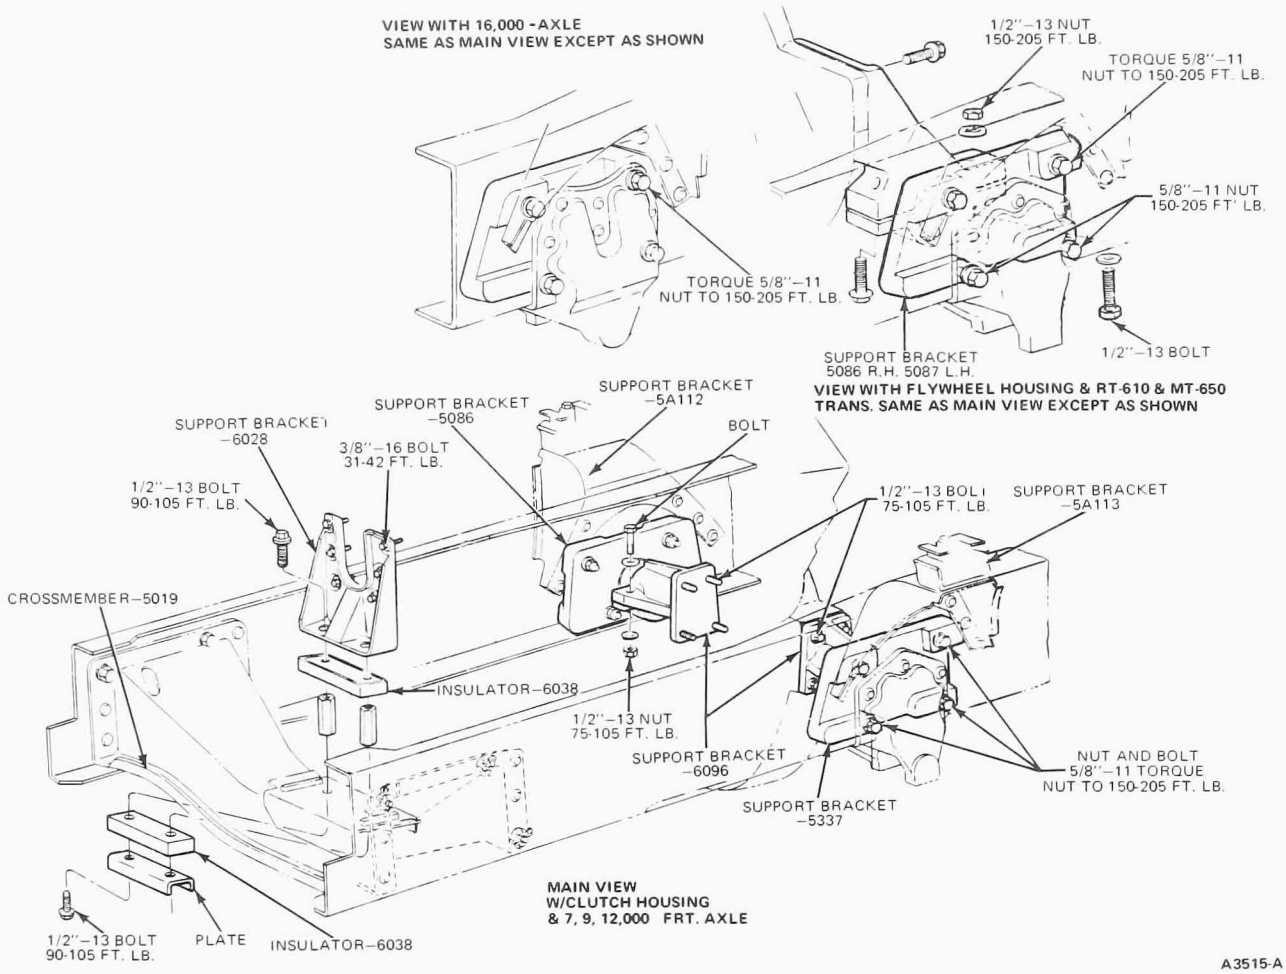

FIG. 1 Engine Supports—6V-53N Engine

Install and torque the attaching bolts to specification.

2. Lower the engine and remove the jack.
3. Install and torque the capscrews in each engine rear support bracket and cap.
4. Torque the two engine front support clamp bolts (Figs. 2 and 3) to specification if they were loosened.
5. On W-Series trucks, return the cab to its normal position and secure it with the cab locks.

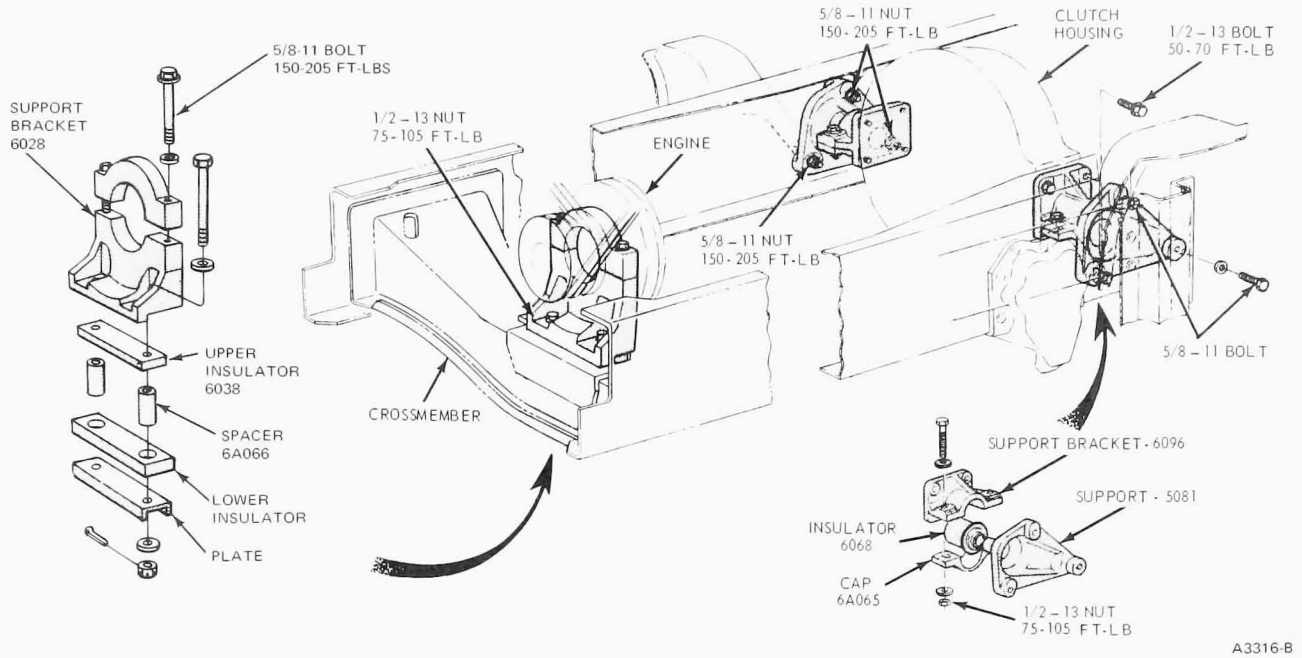

FIG. 2 Engine Support—6-71N Engine

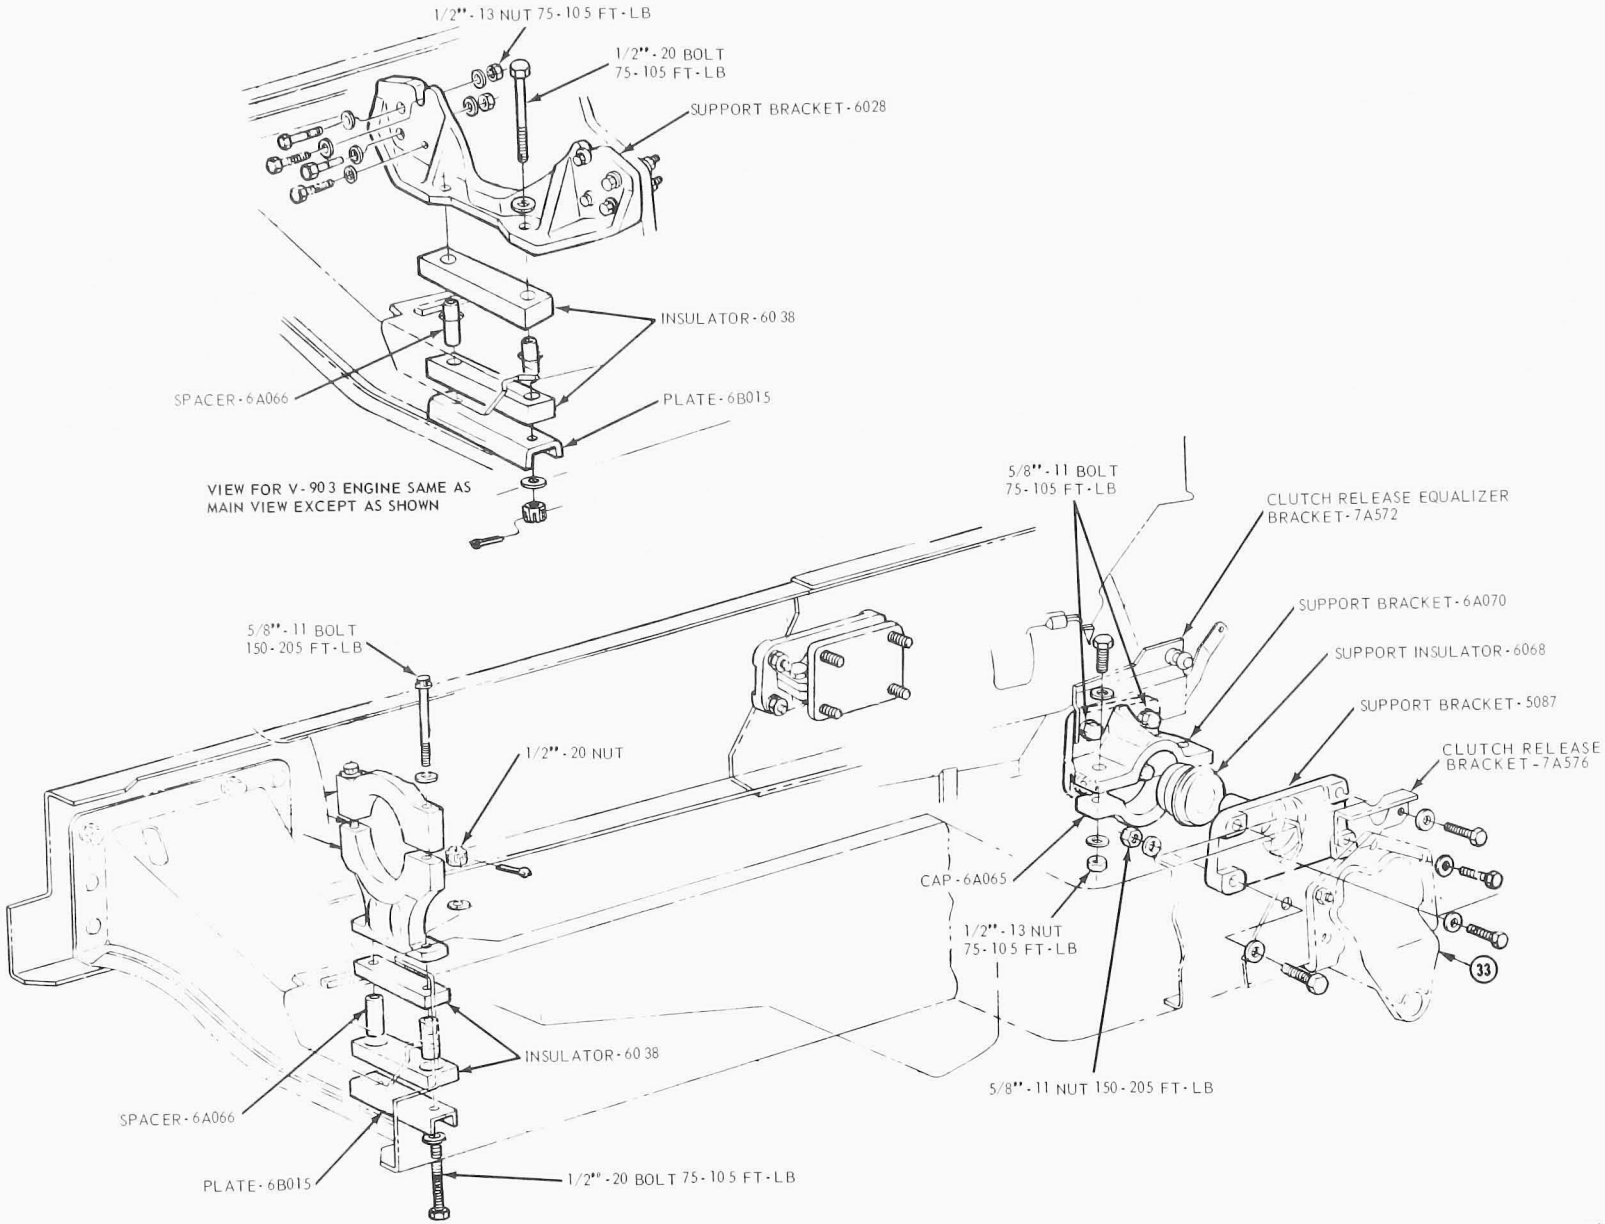

FIG. 3 Engine Supports 8V-71N and V903 Engines

REMOVAL AND INSTALLATION

The 6-V 53N engine installation is shown in Fig. 5. The following engine removal and installation procedure is basic and applies to the 8V-71N, 6-71N and the 6-V 53N engines.

The 8V-71N engine installation is shown in Fig. 4.

ENGINE ASSEMBLY

Removal

1. Release the cab locks and tilt the cab all the way forward if working on a W-Series truck. If working on an L-Series truck, disconnect the hood check cables and springs, then support the hood and fenders in a vertical position.
2. Drain the cooling system and the crankcase. Disconnect the battery cables from the batteries.
3. Disconnect the radiator hoses and automatic shutter air line. Remove the radiator attaching bolts and remove the radiator and shroud as an assembly.
4. Disconnect the oil filter (Luber-Finer) oil lines at the engine.
5. Loosen the hose clamps and remove the inlet air tube and hoses from the air shut-down housing and air cleaner outlet duct.
6. Disconnect the fuel return line from the fuel return manifold. Disconnect the fuel supply line at the fuel strainer. Remove the lines and attaching clips from the engine.
7. Disconnect the air compressor air lines at the compressor.
8. Disconnect the alternator leads and identify them for connection to the proper terminals. Disconnect the leads from the oil pressure and temperature sending units and coolant temperature sending unit. Remove the engine wiring harness from the clips and position it out of the way.
9. Disconnect the fuel shut-off valve lead. Disconnect the tachometer cable. Disconnect the engine stop cable from the air shut-down housing air valve.
10. Disconnect the muffler inlet pipes at the exhaust manifolds and inlet pipe adapters. Remove the inlet pipes.
11. Remove the power steering pump adjusting and mounting bolts and position the pump out of the way. Disconnect the accelerator linkage.
12. Disconnect the heater hoses.
13. Disconnect the starter cables.
14. Disconnect the engine rear supports. Disconnect the engine front support.

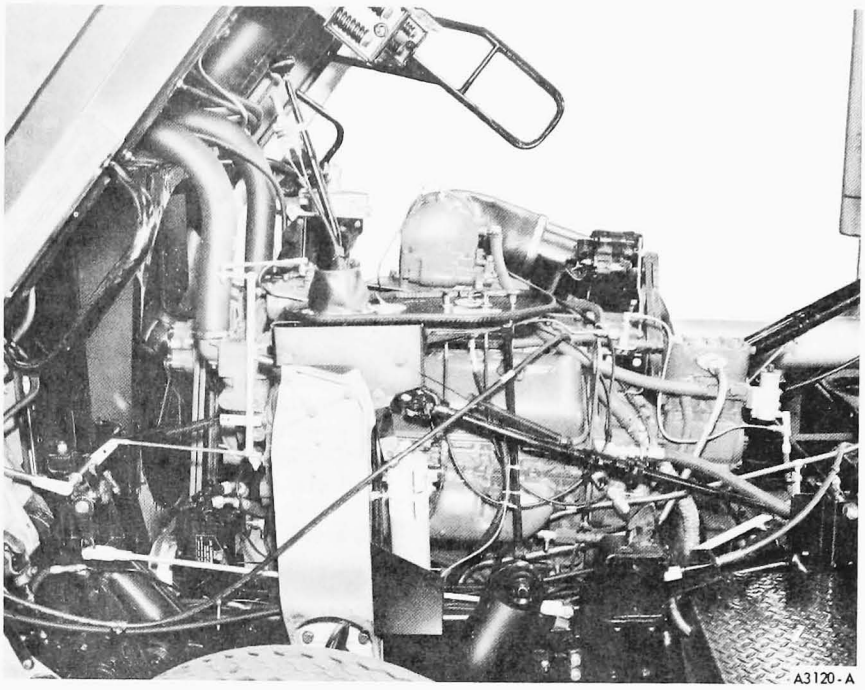

FIG. 4 8V-71N Engine Installed in W-Series Vehicle

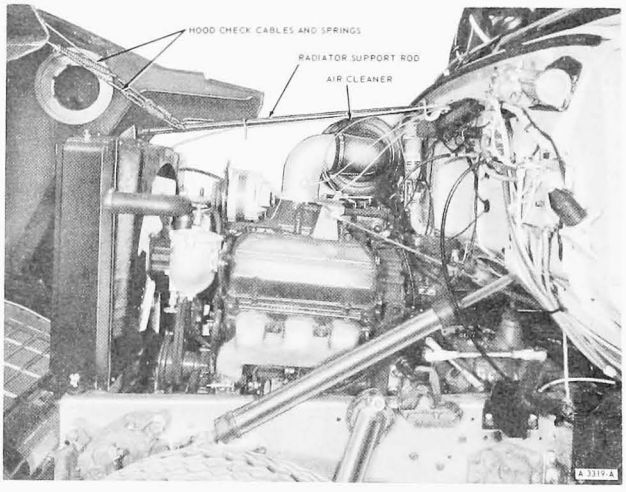

FIG. 5 6-V 53N Engine Installed in L-Series Vehicle

15. Support the transmission with a jack. Disconnect the clutch linkage (slave cylinder) as necessary. Remove the transmission to engine flywheel housing bolts.
16. Use a hoist and lifting sling (use a spreader bar type) to raise the engine. Separate the engine from the transmission. Carefully remove the engine and install it on a work stand or skid. Remove the hoist and lifting sling.

Installation

1. Attach a hoist and lifting fixture to the engine lifting brackets. Remove the engine from the skid or work stand.
2. Carefully lower the engine into the chassis. Make sure the exhaust manifolds are properly aligned with the muffler inlet pipes, and that the clutch disc is properly centered on the transmission input shaft (Fgroup 16), then slide the engine back onto the transmission. Install the transmission attaching bolts.
3. Install the front and the rear supports.
4. Connect the starter cable.
5. Connect the heater hoses.
6. Install the muffler inlet pipe(s) using new gasket(s) at the exhaust manifold(s). Tighten the nuts and clamp(s) to specifications.
7. Connect the accelerator linkage. Install the power steering pump on the engine. Adjust the belt tension to specifications.
8. Connect the hand throttle control. Attach the tachometer cable. Connect the fuel shut-off valve lead. Connect the engine stop cable to the air shut-down housing air valve.
9. Position the engine wiring harness on the engine and secure it with the harness clips. Connect the oil pressure and temperature sending unit leads. Connect the coolant temperature sending unit wire. Connect the alternator leads to the proper alternator terminals.
10. Install the compressor air lines.
11. Position the fuel lines on the engine and install the attaching clips. Connect the fuel supply line to the fuel strainer. Connect the fuel return line to the fuel return manifold.
12. Install the inlet air tube and hoses to the air shut-down housing and air cleaner outlet duct. Tighten the hose clamps.
13. Connect the oil filter (Luber-Finer) oil lines to the engine.
14. Install the radiator and shutter assembly. Connect the radiator hoses and shutter air hose.
15. Connect the battery cables to the batteries. Fill and bleed the cooling system. Fill the crankcase.
16. Lower the cab and lock it in position if working on a W-Series truck. If working on an L-Series truck, install the radiator support bar and connect the hood check cables and springs.
17. Operate the engine and check for fuel, oil, air and coolant leaks. Check the crankcase oil level and add oil as necessary.
18. Adjust the clutch free-travel.
19. Adjust the accelerator linkage as required.

PART 22-05 Ford V-8 Diesel Engines

Applies To B-, C-, F-, L-, LN-, LNT-, LT, LTS-Series

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ENGINE		ENGINE SUPPORTS - Continued	
Description	05-01	Removal	05-01
Installation	05-05	Rear Support Insulators	
Removal	05-05	Installation	05-01
ENGINE SUPPORTS		Removal	05-01
Front Support Insulators			
Installation	05-01	SPECIFICATIONS	05-05

DESCRIPTION

The Ford V-8 Diesel Engines are direct injection, 4-stroke cycle, 90 degree V-8's. All use the same basic head and block, but vary rpm, stroke and fuel injector settings to produce four different horsepower ratings. The oil pan and flywheel configurations depend upon engine application. The cylinders are numbered from the front with the odd numbers, 1, 3, 5 and 7 located in the right bank (as viewed from the flywheel). The firing order is 1-2-7-3-4-5-6-8.

The engines are of the overhead valve design and have one intake and one exhaust valve per cylinder. The camshaft, geared and timed to the crankshaft, actuates rocker arms and valves through mechanical lifters and push rods. There is a single rocker arm shaft for each head. The shaft is mounted in an aluminum support which spaces the rocker arms. The entire guide, shaft and arm assembly is removed and installed as a unit.

The crankshaft pulley and vibration damper are integral units on the 1150 and 1160 Engines. The 1140 and 1145 Engines do not use a vibration damper.

ADJUSTMENTS

When installing nuts or bolts (refer to the end of this Part for torque specifications), oil the threads with light weight engine oil. **Do not oil threads that require oil-resistant or water-resistant sealer.**

ENGINE SUPPORTS

FRONT SUPPORT INSULATORS

Removal—F-B 6000-7000 and L, LN, LNT, LT, LTS-8000

1. Remove the two engine front support-to-upper insulator attaching bolts (Figs. 1 and 2).
2. Remove the two lower insulator attaching bolts and remove the insulator and spacers.
3. Place a wood block on a jack, then raise the engine high enough to remove the upper insulator.

Removal—C-6000-7000-8000

1. Remove the two lower attaching nuts (Fig. 3).
2. Using a wood block and jack, raise the engine for wrench clearance and remove the two bolts and nuts attaching the insulator to the engine support. Remove the insulator (Fig. 3).

Installation—F-B-6000-7000 and L, LNT, LTS-8000

1. Position a new upper insulator on the support bracket (Figs. 1 and 2).
2. Lower the engine enough to start the attaching bolts and washers in the spacers, then remove the jack.
3. Secure the lower insulator to the support bracket with the attaching bolts and washers. Torque the four insulator attaching bolts to specification.

Installation—C-6000-7000-8000

1. Position the insulator on the engine support and install the upper attaching bolts and nuts.
2. Lower the engine and install the lower attaching nuts and washers. Torque all attaching bolts and nuts to specifications.

REAR SUPPORT INSULATORS

Removal—F and B-6000-7000 and C-Series

1. Remove the bolts from the engine rear supports (Figs. 1 and 3).
2. With a hoist or jack and block of wood, raise the engine by lifting the transmission. Raise the engine only enough for clearance to remove the insulators and spacers.

Installation—F and B-6000-7000 Series

1. Position the engine rear support insulators and spacers on the crossmember (Figs. 1 and 3).
2. Lower the engine until engine support brackets almost touch the insulators. Install the support bolts and lock washers.
3. Lower the engine and remove the hoist or jack.
4. Tighten all bolts to specifications. Bend tabs on lock washers.

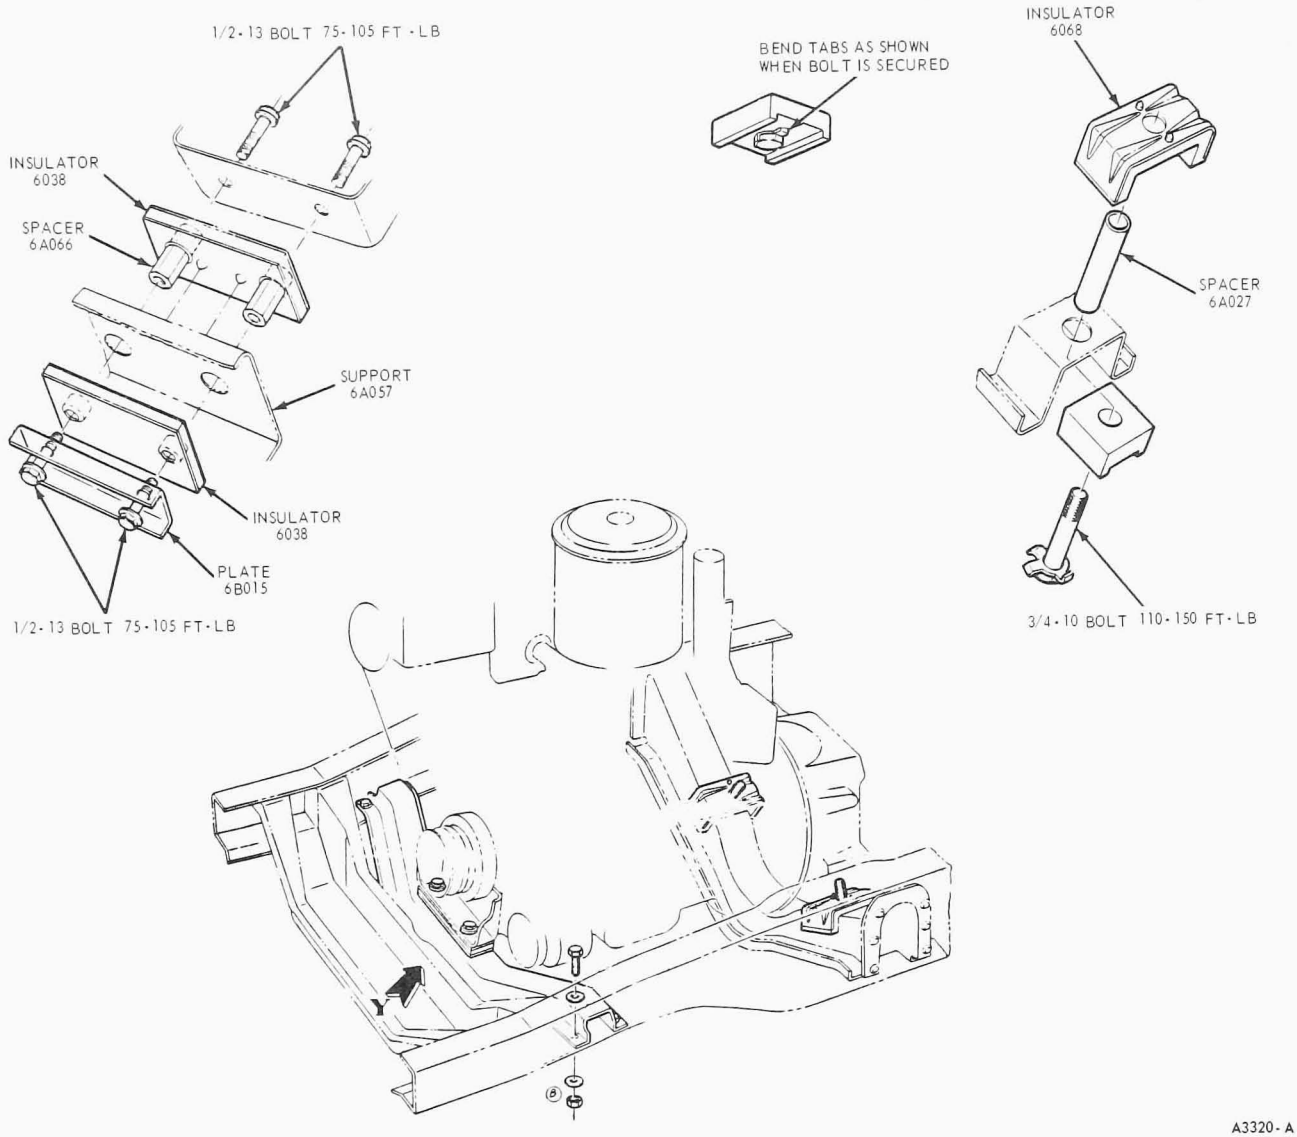

FIG. 1 Ford V-8 Engine Supports F and B-6000-7000 Series

Removal—L, LN, LNT, LT, LTS-8000 Series

1. Remove the two bolts from the engine rear support brackets and remove the caps.
2. Place a wood block on a jack and raise the rear of the engine just enough to remove the tubular insulators from the rear supports.

Installation—L, LN, LNT, LT, LTS-8000 Series

1. Position new insulators on the engine rear supports (Fig. 2).
2. Lower the engine and remove the jack.
3. Install and torque the bolts in each engine rear support bracket and cap.

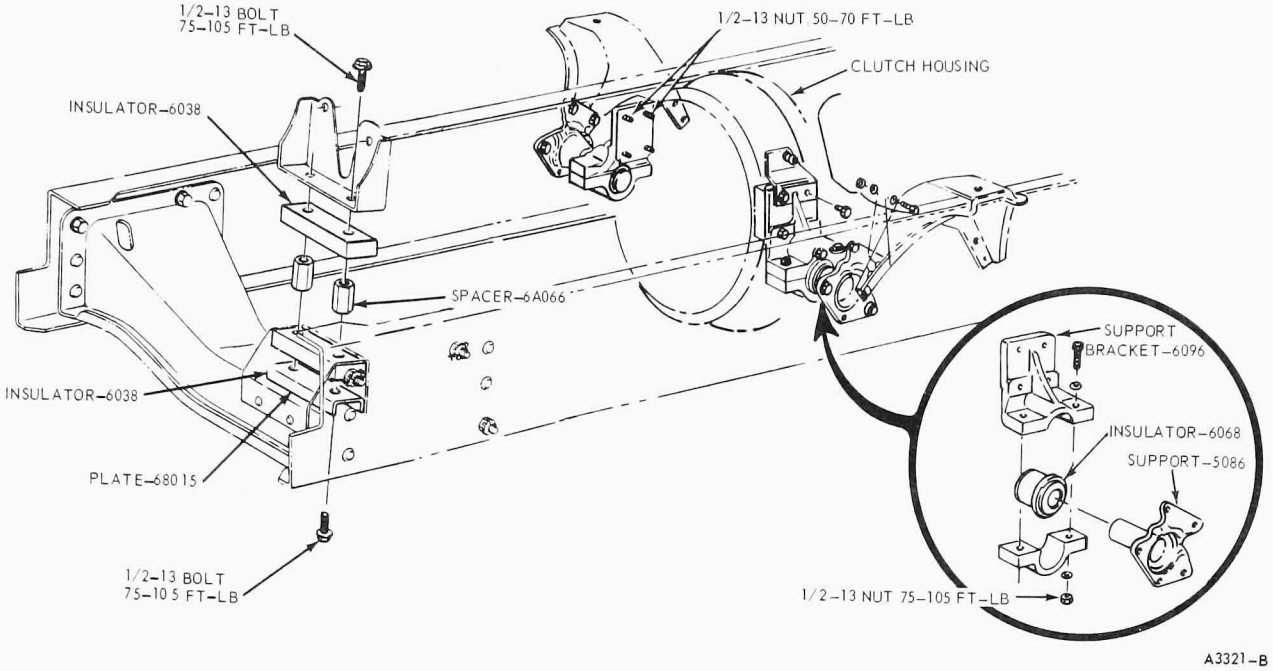

FIG. 2 Ford V-8 Engine Supports—L, LN, LNT, LT, LTS-8000

REMOVAL AND INSTALLATION

ENGINE ASSEMBLY

Removal

1. Disconnect the battery ground cable from the battery.
2. Drain the cooling system.
3. Release the air pressure in the air supply tank.
4. Disconnect the hood check cable and springs. Support the hood and fenders in a vertical position. Remove the radiator support rod.
5. Remove the radiator and shroud and the fan from the vehicle.
6. Remove the air cleaner and air cleaner attaching bolt.
7. Remove the alternator and identify each wire for installation.
8. Disconnect the power steering hoses if so equipped.
9. Disconnect the heater hoses and positon them out of the way.
10. Disconnect the tachometer drive line from the engine and position it out of the way.
11. Disconnect the throttle linkage from the injection pump.
12. Disconnect the fuel inlet and fuel return lines.
13. Disconnect the air lines from the air compressor.
14. Disconnect the engine shut-off solenoid, the oil sending unit and the temperature gauge sending unit.
15. Disconnect all wires from the starter motor, identify for installation and position them out of the way.
16. Disconnect both exhaust pipes from the exhaust manifolds.
17. Remove the transmission as detailed in Group 16.
18. Disconnect the clutch release mechanism at the clutch release lever.
19. Connect the hoist and lifting tool (LRE1850) to the engine lifting eyes.
20. Remove attaching parts from the engine front support per instructions in this Part.
21. Be sure the lifting tool is tight enough to support weight of engine, then disconnect the engine rear mounts per instructions in this Part.
22. Position all lines, wires and accessories out of the way and lift the engine from vehicle.

Installation

1. Use a hoist and lifting tool (LRE-1805) to lower the engine into position. Start the engine front mount attaching parts and position the engine rear mounts.
2. Install all engine mount bolts and/or nuts and torque to specifications.
3. Install the transmission as detailed in Group 16.
4. Connect the clutch mechanism at the clutch release lever, and adjust the clutch as required (Group 16).
5. Connect both exhaust pipes to the exhaust manifolds.
6. Connect all wires to the starter motor, installing each wire on its respective terminal.
7. Connect the engine shut-off solenoid, the oil sending unit and the temperature gauge sending unit.
8. Connect all air lines to the air compressor.
9. Connect all fuel lines.
10. Connect throttle linkage at injection pump and connect tachometer drive line to engine.
11. Connect heater hoses and power steering lines.
12. Install alternator and connect all wires to their respective terminals.
13. Install the air cleaner.
14. Install the fan and the radiator with shroud. Install the radiator support rod.
15. Install all drive belts and tighten to specifications.
16. Install the hood check cables and springs.
17. Fill cooling system and install the hood.
18. Connect battery ground cable to battery.
19. Check oil and coolant levels, replenish as required.
20. Close drain on air supply tank.
21. Start the engine and check for any oil leaks.
22. Before attempting to move the vehicle, be sure the air supply tank is up to pressure.

All 1973 truck gasoline engines are equipped with the Imco Exhaust Emission Control System. Positive crankcase ventilation is continued on all gasoline-powered trucks.

E-Series and F-100 trucks using a 240-1V, is equipped with a Transmission Regulated Spark Control System (TRS) for closer control of the spark advance during low speed and idle operation. This control is designed to further reduce engine exhaust emission. Service information on emission controls are given in Volume VI of this manual.

Distributor specifications (Parts 23-10 and 23-16) have been, in some cases, changed. New distributor part numbers reflect these changes.

Other than the above, the 1973 ignition systems are basically the same as the 1972 systems.

To maintain the required exhaust emission levels, the carburetor must be kept in good operating condition and be adjusted to specifications, and the engine should be in good operating condition.

Additional engine performance checks are required to keep the exhaust emissions at the specified minimum pollutant level. Refer to the applicable owners manual for these performance checks and the recommended intervals.

When performing tests, adjustments or repairs to the engine, ignition system or fuel system, it is essential to follow the procedures and specifications in Groups 21, 23 and 24 of this manual.

This part covers conventional ignition system description, test, adjustments and repair operations.

The vacuum control valve (PVS Valve) is covered in Part 23-15.

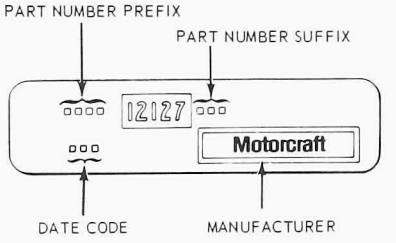

FIG. 1 Distributor Identification

Complete engine performance specifications, including engine, ignition and fuel system components is covered in the Specifications Booklet. All other specifications for ignition system components are covered in Parts 23-10 and 23-16.

For distributor removal, disassembly, assembly, installation, major repair procedures and specification, refer to the pertinent part of this group.

DISTRIBUTOR IDENTIFICATION

The distributor identification number is stamped on the distributor housing. The basic part number for ungoverned distributors is 12127. To procure replacement parts, it is necessary to know the part number prefex and suffix and, in some cases, the design code change (Fig. 1).

Always refer to the Master Parts Catalog for parts usage and interchangeability before replacing a distributor or a component part for a distributor.

TESTING

GENERAL INFORMATION

CONVENTIONAL IGNITION SYSTEM

The conventional ignition system consists of a primary (low voltage) and a secondary (high voltage) circuit (Fig. 2).

The primary circuit consists of the:

1. Battery.
2. Ignition switch.
3. Primary circuit resistance wire.
4. Primary windings of the ignition coil.
5. Breaker points.
6. Condenser.

The secondary circuit consists of the:

1. Secondary windings of the ignition coil.
2. Distributor rotor.
3. Distributor cap.
4. High tension wires.
5. Spark plugs.

When the breaker points are closed, current flows from the battery through the ignition switch to the primary windings in the coil, then to ground through the closed breaker points. When the breaker points open, the magnetic field built up in the primary windings of the coil moves through the secondary windings of the coil producing high voltage. **High voltage is produced each time the breaker points open.** The high voltage flows through the coil high tension lead to the distributor cap where the rotor distributes it to one of the spark plug terminals in the distributor cap. This process is repeated for every power stroke of the engine.

TRANSISTOR IGNITION SYSTEM

The permatuned transistor ignition system is available on the 361, 391, 401, 477 and 534 V-8 C10 engines. Figure 3 shows a schematic of the transistor ignition system.

The ignition coil primary in the transistor system is designed to draw 12 amperes peak current, or approximately 5.5 amperes average current as indicated on an ammeter, in order to provide high spark plug voltage at the higher engine speeds.

The transistor in the system acts as a heavy duty switch or relay. It is similar in action to a horn relay, except that it has no moving parts, and thus acts with very little time lag. The transistor is connected between the battery and the coil, and is used to make and break the coil primary circuit.

The distributor controls the transistor. The 7.1-7.9 ohm resistor, connected between the distributor and the transistor (in the wiring harness), limits the transistor control current (and distributor point current) to 0.5 ampere. The distributor low point current eliminates pitting and gives long distributor point life.

The amplifier assembly (Fig. 4) is mounted away from the engine to protect the parts from engine heat.

A ceramic ballast resistor block is mounted in the engine compartment.

DIAGNOSIS

Refer to the appropriate Section of the Truck Diagnosis Manual for diagnosis procedures.

TRANSISTOR IGNITION SYSTEM

Do not use any testing procedures or conventional shortcuts other than those listed below, or extensive damage can result to the system.

TESTS

SPARK INTENSITY TEST

Trouble Isolation

1. Disconnect the brown wire from the starter relay I terminal and the red and blue wire from the starter relay S terminal.
2. Remove the coil high tension lead from the distributor cap.
3. Turn on the ignition switch.
4. While holding the high tension lead approximately 3/16 inch from the cylinder head or any other good ground, crank the engine by using an auxiliary starter switch between the starter relay battery and S terminals.

If the spark is good, the trouble lies in the secondary circuit.

If there is no spark or a weak spark, the trouble is in the primary circuit, coil to distributor high tension lead, or the coil.

Primary Circuit

A breakdown or energy loss in the primary circuit can be caused by: defective primary wiring, or loose or corroded terminals; burned, shorted, sticking or improperly adjusted breaker points: a defective coil; or defective condenser.

A complete test of the primary circuit consists of checking the circuit from the battery to the coil, the circuit from the coil to ground, and the starting ignition circuit.

Excessive voltage drop in the primary circuit will reduce the secondary output of the ignition coil, resulting in hard starting and poor performance.

To isolate a trouble in the primary circuit, use a voltmeter and perform the following tests: Battery to Coil; Starting Ignition Circuit; Resistance Wire; Coil to Ground; or Breaker Points.

Secondary Circuit

A breakdown or energy loss in the secondary circuit can be caused by: fouled or improperly adjusted spark plugs; defective high tension wiring; or high tension leakage across the coil, distributor cap or rotor resulting from an accumulation of dirt.

To check the spark intensity at the spark plugs, thereby isolating an ignition problem to a particular cylinder, proceed as follows:

1. Disconnect a spark plug wire (by hand only). **Check the spark intensity of one wire at a time.**
2. Install a terminal adapter in the terminal of the wire to be checked. Using insulated pliers hold the adapter approximately 3/16 inch from the exhaust manifold and crank the engine, using a remote starter switch. The spark should jump the gap regularly.
3. If the spark intensity of all the wires is satisfactory, the coil, condenser, rotor, distributor cap and the secondary wires are probably satisfactory.

If the spark is good at only some wires, check the resistance of the faulty leads.

If the spark is equal at all wires, but weak or intermittent, check the coil, distributor cap and the coil to distributor high tension wire. The wire should be clean and bright on the conducting ends, and on the coil tower and distributor sockets. The wire should fit snugly and be bottomed in the sockets.

Battery to Coil Voltmeter Test

1. Connect the voltmeter leads as shown in Fig. 5.
2. Install a jumper wire from the distributor terminal of the coil to a good ground on the distributor housing.
3. Turn the lights and accessories off.
4. Turn the ignition switch on.
5. If the voltmeter reading is between 4.5 and 6.9 volts, the primary circuit from the battery to the coil is satisfactory.

6. If the voltmeter reading is greater than 6.9 volts, check the following:

The battery and cables for loose connections or corrosion.

The primary wiring for worn insulation, broken strands, and loose or corroded terminals.

The resistance wire for damage.

The starter relay to ignition switch for malfunctions.

If the voltmeter reading is less than 4.5 volts the resistance wire should be replaced.

Starting Ignition Circuit Voltmeter Test

1. Connect the voltmeter leads as shown in Fig. 5.
2. Disconnect and ground the coil to distributor high tension lead at the distributor.
3. With the ignition switch off, crank the engine by installing a jumper wire between the battery and the S terminal of the starter relay while observing the voltage drop.
4. If the voltage drop is 0.3-0.4 volt or less, the starting ignition circuit is satisfactory.
5. If the voltage drop is greater than 0.4 volt, clean and tighten the terminals in the circuit or replace the wiring as necessary.

Ignition Switch Voltmeter Test

1. Connect the voltmeter leads as shown in Fig. 6.
2. Install a jumper wire from the distributor terminal of the coil to a good ground on the distributor body.
3. Turn all of the accessories and lights off.
4. Turn the ignition switch on.
5. If the voltmeter reading is 0.3 volt or less, the ignition switch and the relay to switch wire are satisfactory.
6. If the voltmeter reading is greater than 0.3 volt, the ignition switch and/or the wire are defective.

Resistance Wire Voltmeter Test

1. Connect the voltmeter leads as shown in Fig. 7.
2. Install a jumper wire from the DIST terminal of the coil to a good ground.
3. Turn all of the accessories and lights off.
4. Turn the ignition switch on.
5. If the voltmeter reading is between 6.6 and 4.5 volts, the resistance wire is satisfactory.
6. If the voltmeter reading is greater than 6.6 volts, or less than 4.5 replace the resistance wire.
7. Turn the ignition switch off. Disconnect the voltmeter leads. Remove the jumper wire connected to the coil DIST terminal and the distributor. Remove the jumper wire connected to the coil BAT terminal and the coil BAT lead. Connect the BAT lead to the BAT terminal and go on to the Coil-to-Ground Test.

Coil-to-Ground Voltmeter Test

1. Connect the voltmeter leads as shown in Fig. 8.
2. Close the breaker points.
3. Turn all lights and accessories off.
4. Turn the ignition switch on.
5. If the voltmeter reading is 0.25 volt or less, the primary circuit from coil-to-ground is satisfactory.
6. If the voltmeter reading is greater than 0.25 volt, test the voltage drop between each of the following:

The coil and the breaker point connections of the coil-to-distributor primary wire.

The movable breaker point and the breaker plate.

The breaker plate and the distributor housing.

The distributor housing and engine ground.

7. Turn the ignition switch off. Disconnect the voltmeter leads.

Breaker Points Check

Clean and inspect the breaker points by following the procedure under Cleaning and Inspection in this Part.

The breaker point dwell can be checked with a distributor tester or a dwell meter by following the procedure under Distributor Tests in this section of the manual.

The breaker point resistance can be checked with a Rotunda RE-1416 distributor tester by following the procedure under Distributor Tests in this section of the manual.

Coil Test

Clean and inspect the coil by following the procedure under Cleaning and Inspection in this Part.

Check the coil on a coil tester by following the manufacturers instructions. Check for ohms resistance both primary and secondary. Also check the amperage draw both with the engine idling and stopped. These checks should all fall within specifications.

Secondary (High Tension) Wires Resistance Test

The secondary wires include the wires connecting the distributor cap to the spark plugs and the wire connecting the center terminal of the distributor cap to the center terminal of the ignition coil.

Clean and inspect the secondary wiring by following the procedure under Cleaning and Inspection in this Part.

These wires are the radio resistance-type which filter out the high frequency electrical impulses that are the source of ignition noise interference. The resistance of each wire should not exceed 1000 ohms per inch. When checking the resistance of the wires or setting ignition timing, do not puncture the wires with a probe. The probe may cause a separation in the conductor.

When removing the wires from the spark plug, grasp and twist the moulded cap using the hand only, then pull the cap off the spark plug. Do not pull on the wire because the wire connection inside the cap may become separated or the insulator may be damaged.

To check the spark intensity at the spark plugs, proceed as follows:

1. Disconnect a spark plug wire. Check the spark intensity of one wire at a time.
2. Install a terminal adapter in the terminal of the wire to be checked. Hold the adapter approximately 3/16 inch from the exhaust manifold or good ground with insulated pliers and crank the engine, using a remote starter switch. The spark should jump the gap regularly.
3. If the spark intensity of all the wires is satisfactory, the coil, condenser, rotor, distributor cap and the secondary wires are probably satisfactory.

If the spark is good at only some wires, check the resistance of the faulty leads.

If the spark is equal at all wires, but weak or intermittent, check the coil, distributor cap and the coil to distributor high tension wire.

Spark Plug Test

Inspect, clean and gap the plugs. After the proper gap is obtained, check the plugs on a testing machine. Compare the sparking efficiency of the cleaned and gapped plug with a new plug. Replace the plug if it fails to meet 70 percent of the new plug performance.

DISTRIBUTOR CHECKS

Distributor Shaft End Play

If the shaft end play is not to specifications, check the location of the gear on the shaft (6-cyl. engine distributor), or the distributor shaft collar, (dual advance 8-cyl. engine distributor).

6-Cyl. Engine Distributor

The shaft end play can be checked with the distributor installed on the engine.

1. Mount a dial indicator on the distributor so that the indicator tip rests on the top of the distributor shaft.
2. Push the shaft down as far as it will go and set the dial indicator on zero.
3. Pull the distributor shaft upward as far as it will go and read the end play. The end play should be within

specifications with the distributor removed or installed.

8-Cyl. Engine Distributor

1. Remove the distributor from the engine.
2. Place the distributor in the holding tool and clamp it in a vise.
3. Push the distributor shaft upward as far as it will go, and check the end play with a feeler gauge placed between the collar and the distributor base. The end play should be within the specified limits. If the shaft end play is not to specifications, check the location of the distributor shaft collar.

DISTRIBUTOR TESTS—ROTUNDA ARE-27-44 DWELL TESTER

Test Connections Conventional Ignition System Distributor

1. Disconnect the distributor primary wire at the coil. Connect a short jumper wire to the DIST terminal of the coil and the distributor primary wire. Connect the red lead to the jumper wire.
2. Connect the black lead to a good ground on the engine.

Transister Ignition System distributor

1. Connect the red lead to either terminal shown in Fig. 3.
2. Connect the black lead to either tach block terminal shown in Fig. 3.

Dwell Angle Check

1. Disconnect and plug the distributor vacuum line(s). Connect the tester.
2. Turn the test control knob to the set position.
3. Adjust the set control knob until the hand on the dwell meter lines up with the set line.
4. Start the engine and let it idle.
5. Turn the test control knob to the 8 CYL position.
6. Read the dwell angle on the dwell meter and compare the reading to specifications.
7. Turn off the engine.
8. If the dwell angle was below the specified amount, the breaker point gap is too wide. If the dwell angle was above the specified amount, the breaker point gap is too close.

If the dwell is to specifications, turn the test selector knob to the OFF position and disconnect the tester leads, and jumper wire; then connect the distributor vacuum line(s).

Dwell Angle Adjustment

If the dwell angle is not within specifications, proceed as follows:

1. Remove the coil high tension lead from the distributor and ground it.
2. Remove the distributor cap and place it out of the way.
3. Loosen the breaker point attaching screw near the breaker point contacts.
4. With the ignition on, crank the engine with an auxiliary starter switch.
5. Release the auxiliary starter switch and tighten the breaker point attaching screw.
6. Since the adjustment may have changed when the attaching screw was tightened, crank the engine again with the auxiliary starter switch and check the dwell. When the dwell is properly adjusted, remove the jumper wire, auxiliary starter switch and tester leads and install the distributor cap and coil high tension lead.

Connect the distributor vacuum line(s).

DISTRIBUTOR TESTS—ROTUNDA DISTRIBUTOR TESTER

Mounting Distributor ARE-236 Tester

1. Adjust the distributor support arm in relation to the distributor shaft length.
2. Set the distributor in the support arm and enter the lower end of the distributor shaft in the Syncrograph chuck.
3. Tighten the chuck on the distributor shaft, using the wrench located near the support arm column.
4. Align the distributor shaft by shifting the support arm and distributor, and tighten the clamp screw.
5. Clamp the distributor securely in the distributor support arm clamp so that it will not turn in its mounting.
6. Connect the Synchrograph test lead to the primary wire of the distributor.
7. Connect the tester vacuum line to the vacuum diaphragm fitting. Since the transistor ignition distributor does not have a condenser, (the wire has been cut) it will be necessary to install one in the circuit of the tester (Fig. 9).

Mounting Distributor ARE-14-16 Tester

1. Clamp the distributor securely in the distributor support arm clamp so that it will not turn in its mounting.
2. Loosen the hand-operated locking screw on the side of distributor support arm, and adjust the support arm column up or down by turning the crank on the knob at the top of the column until the distributor shaft or adapter shaft can be securely fastened in the driving chuck.
3. Tighten the drive chuck securely to the distributor drive shaft.
4. Rotate the drive chuck by hand to make sure the distributor shaft turns freely and then tighten the locking screw on the distributor support arm.
5. Connect the Synchrograph test lead to the primary or distributor-transistor lead wire of the distributor.

Breaker Point Resistance ARE-14-16 Tester

1. Turn the test selector to the POINT RES. position.
2. Rotate the chuck by hand until the distributor breaker points are closed.
3. The meter pointer on the cam angle meter should read in the OK zone at the left side of the meter scale. If the meter pointer does not fall in the OK zone, there is excessive resistance caused by a faulty contact across the distributor points, a faulty primary lead, or a poorly grounded base plate. A faulty contact across the distributor points indicates improper spring tension or burned or pitted points.

Insulation and Leakage ARE-236 and ARE-14-16 Testers

1. Turn the test selector to the cam angle position and rotate the chuck by hand until the distributor breaker contacts are open.
2. The cam angle meter should show a zero reading. If a zero reading is not obtained, a short circuit to ground exists.

A short could be caused by poor primary wire insulation, a shorted condenser or a short between the breaker arm and breaker plate.

Mechanical Operation—Are-236 and ARE-14-16 Testers

1. Turn the OFF, SET, CAM, SYNC. switch to the SET position.
2. Adjust the SET TACH control so that tachometer pointer is on the SET line.
3. Turn the OFF, SET, CAM, SYNC. switch to the SYNC. position.
4. On an ARE-14-16 Tester, turn the test selector to the SYNCHRO. position and check to make sure that the drive chuck is securely tightened on the distributor shaft.
5. Turn the MOTOR switch to the LEFT for 8 cylinder setting.
6. Adjust the speed control to vary the distributor speed between 400 and 4000 engine rpm, or at the maximum speed of the engine on which the distributor is used. Erratic or thin faint flashes of light preceding the regular flashes as the speed of rotation is increased can be

due to weak breaker arm spring tension or binding of the breaker arm on the pivot pin.

7. Operate the distributor at approximately 2500 engine rpm and move the protractor scale so that the zero degree mark on the scale is opposite one of the neon flashes. The balance of all the flashes should come within 1 degree, plus or minus, evenly around the protractor scale. A variation larger than 1 degree or erratic or wandering flashes may be caused by a worn cam or worn or bent distributor shaft.

Dwell Angle

Disconnect and plug the distributor vacuum line(s).

1. On an ARE-236 Tester turn the OFF, SET, CAM, SYNC. switch to the CAM position. Operate the distributor at about 1000 rpm.
2. On an ARE-14-16 Tester, turn the cylinder selector to the 8 position.

Turn the test selector switch to the cam angle position and operate the distributor at approximately 1000 engine rpm.

3. Adjust the breaker point gap until the dwell angle is to specifications. Connect the distributor vacuum line(s).

Breaker Plate Wear

A worn breaker plate on the distributor will cause the breaker point gap and contact dwell to change as engine speed and load conditions are varied.

Adjust the test set to 0 degree advance, 0 inches vacuum, and 100 rpm. Adjust the dwell angle to 26 degrees. Apply vacuum to the distributor diaphragm and increase it very slowly while observing the indicated dwell angle. The maximum dwell angle variation should not exceed 4 degrees when going from zero to maximum vacuum at constant rpm. If the dwell angle variation exceeds this limit, there is excessive wear at the stationary subplate pin or the diaphragm rod is bent or distorted.

Distributor Advance and Retard Check—On Engine

Check the initial ignition timing, centrifugal advance, vacuum advance, and vacuum retard (dual-diaphragm distributor), following the procedure under Initial Ignition Timing Adjustment.

DISTRIBUTOR SPARK ADVANCE TEST—ARE-236 AND ARE-14-16 TESTERS

The spark advance is checked to determine if the ignition timing advances in proper relation to engine speed and load.

Dual Advance Distributor

1. Check the contact dwell. If the contact dwell or the breaker point gap is not within specifications, adjust the breaker points.
2. Check the breaker arm spring tension and adjust it, if necessary.

The dual advance distributor has two independently operated spark advance systems. Each system is adjusted separately. **Adjust the centrifugal advance before adjusting the vacuum advance.**

Centrifugal Advance

1. Do not connect the test set vacuum line to the diaphragm. Set the test set to 0 degree advance and the initial rpm setting listed in the specifications.
2. Operate the distributor in the direction of rotation (counterclockwise) and slowly increase the rpm to the setting specified for the first advance reading listed in the specifications.

If the correct advance is not indicated at this rpm, stop the distributor and bend one spring adjustment bracket to change its tension (Figs. 10 and 11). Bend the adjustment bracket away from the distributor shaft to decrease advance (increase spring tension) and toward the shaft to increase advance (decrease spring tension). After the adjustment is made, identify the bracket.

3. After an adjustment has been made to one spring, check the minimum advance point again.
4. Operate the distributor at the specified rpm to give an advance just below the maximum. If this advance is not to specifications, stop the distributor and bend the other spring bracket to obtain the correct advance.
5. Check the advance at all rpm settings listed in the specifications. Operate the distributor both up and down the rpm range.

Vacuum Advance

1. Connect the test unit vacuum line to the horizontal connection (end of diaphragm). Set the test unit at 0 degree advance, 0 vacuum, and at 1000 rpm.
2. Check the advance at the first vacuum setting given in the specifications.
3. If the advance is incorrect and adjustment is required, disconnect the vacuum line and insert a 1/8 inch socket head wrench in the end of the diaphragm (Fig. 12). Turn the wrench clockwise to increase the vacuum advance or counterclockwise to decrease it.
4. After one vacuum setting has been adjusted, the others should be checked. **Do not change the original rpm setting when going to a different vacuum setting.** If the other settings are not within limits, there is incorrect spring tension, leakage in the vacuum chamber and/or line.

To check the diaphragm for leakage (either, or both on dual diaphragm distributors):

Adjust the vacuum pressure of a distributor test unit to its maximum position. Hold your finger over the end of the tester's vacuum hose and note the maximum reading obtained. **Do not exceed 25 inches Hg.**

If the maximum reading is 25 inches Hg or less, connect the tester's vacuum line to the vacuum fitting on the diaphragm to be tested without changing any of the adjustments. The maximum gauge reading should not be less than it was above. If it is less, the diaphragm is leaking and should be replaced.

DISTRIBUTOR DUAL DIAPHRAGM TEST

Vacuum Advance

1. Disconnect the vacuum lines from both the outer and inner diaphragms. Plug the line removed from the inner diaphragm.
2. Connect a tachometer and increase the idle speed by setting the throttle on the first step of the fast idle cam.
3. Using a timing light observe ignition timing setting.
4. Connect the carburetor vacuum line to the outer diaphragm. The timing should advance immediately. Adjust if necessary.

Vacuum Retard

1. Readjust the engine idle speed to 550-600 rpm.
2. Using a timing light, observe the spark timing.
3. Remove the plug from the manifold vacuum line and connect the line to the inner diaphragm.
4. The timing should retard immediately. Replace the dual diaphragm unit if the retard portion is out of calibration, the advance portion cannot be calibrated to specifications, if either of the diaphragms are leaking.

GOVERNOR TESTS

Velocity Governor

The governor is calibrated for sensitivity and adjusted at the factory. There are no provisions made for

remedying malfunctions of this governor in service except to increase or decrease the governed speed (refer to Velocity Governor Adjustment in Part 23-20). If the governor is inoperative, too sensitive, or not sensitive enough, replace the unit.

The 330 MD engine governor can be adjusted for altitude operation. Refer to Part 23-20 for the procedure.

Vacuum Governor

To determine if the governor is at fault when loss of power and performance are encountered, make the following test:

1. Disconnect the governor vacuum line at the carburetor.
2. Operate the engine under load to determine if the engine reaches governed rpm. **Disconnecting the governor line makes the governor control inoperative. Do not exceed recommended governor engine rpm.**
3. If the engine performs satisfactorily the trouble is the governor control. If the engine does not operate satisfactorily, the trouble is not in the governor system. Connect the governor vacuum line.

If the trouble is in the governor, it can be further localized to the controlling unit, vacuum lines, or the throttle actuating unit as follows:

Connect the governor vacuum line to the carburetor. Disconnect the governor vacuum line at the distributor. Operate the engine at governed speed. **Disconnecting the governor line makes the governor control inoperative. Do not exceed recommended governor engine rpm.** Place a finger over the end of the line.

If there is no change in engine rpm, the trouble is in the throttle actuating unit (on the carburetor).

If the engine speed changed, the trouble is in the controlling unit (on the distributor).

Diagnosis Procedure

Loss of Speed Control. Check for vacuum leaks and the operation of the governor valve in the distributor.

Check for proper sealing of the diaphragm cover.

Check the diaphragm for leaks by removing the vacuum line at the carburetor and attaching a vacuum pump to the fitting at the carburetor. Apply 25 inches Hg following the instructions of the test unit manufacturer. The vacuum reading should not drop off when the vacuum is applied to the diaphragm assembly. If a leak is indicated by the test, replace the diaphragm.

Erratic Operation Under Load. Check for binding of the throttle shaft and throttle lever.

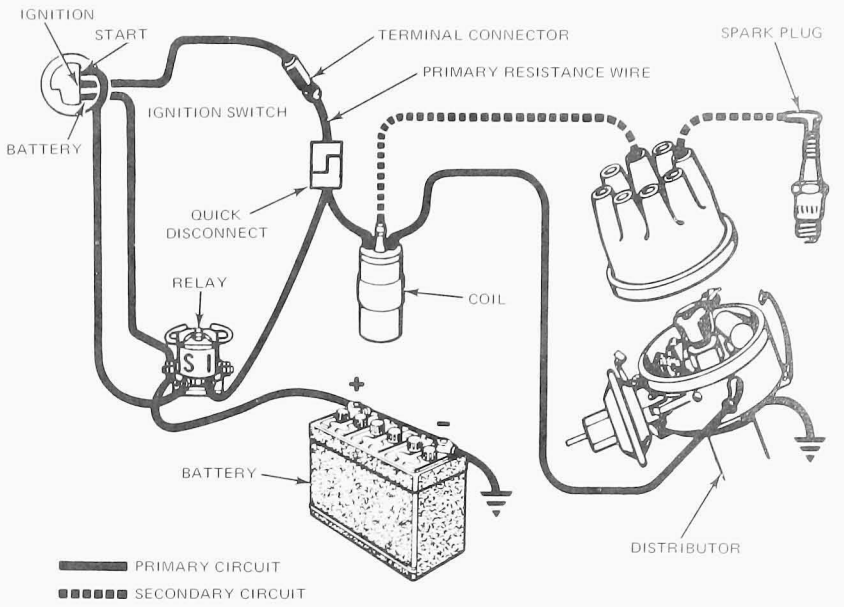

FIG. 2 Typical Conventional Ignition System Circuit

No Governing Action. Vacuum leak in the controlling unit, throttle actuating unit, or in the fittings or lines.

Governor valve in the controlling unit stuck.

Passages in the carburetor blocked.

Over Governing. Passages in the carburetor and/or distributor restricted.

Improper governor adjustment.

Governor spring pin in throttle actuating unit installed in the wrong hole.

Mechanical Governor

If under certain conditions of loading, the engine will not approach the no load governed engine speed within 200-300 rpm, the load limitation of the engine has been exceeded, or the governor throttles the engine too soon, make the following test:

Governor Throttle Linkage

Preliminary Adjustment

1. Disconnect the governor-to-carburetor throttle control rod at the governor.
2. Make sure the throttle control rod is free to operate in all positions.
3. Check the primary spring location on the governor control lever arm. The spring should be in the inner hole on the 2 venturi carburetor, and in the outer hole on the 4 venturi carburetor. Change the spring location if it is not correct.
4. Check the auxiliary secondary spring. Replace the spring if it has been overstretched.
5. To adjust the primary spring tension, loosen the top nut on the eye bolt. Tighten the bottom nut finger tight, then tighten the nut two additional full turns. After adjusting, lock eye bolt in place by tightening bottom nut.
6. With accelerator in wide open throttle position and auxiliary lever fully forward, adjust the governor-to-carburetor throttle control rod to fit in the auxiliary control rod hole. Next, shorten the control rod one more full turn. This will help to avoid compression of the control rod linkage.
7. Attach control rod to the auxiliary lever and depress accelerator pedal to be sure that wide open throttle is achieved.

Engine Speed Final Adjustment

1. Bring engine up to normal operating temperature.
2. Adjust governor to obtain the recommended engine no-load rpm by depressing the accelerator to the full wide-open throttle position. Adjust speed as follows: To increase rpm, loosen the top nut on the primary spring eye bolt and tighten the bottom, (increasing the spring tension). To decrease rpm, loosen the bottom nut and tighten the top nut, (decreasing the spring tension).

ADJUSTMENTS

GENERAL PROCEDURES

Accurate ignition system adjustments are of great importance in the control of hydro-carbon and carbon monoxide emissions for reducing air pollution.

After any adjustment of ignition timing and distributor point dwell, check the distributor automatic advance for proper operation.

To keep engine emissions controlled within the limits of government regulations, the carburetor fuel mixture and idle speed adjustments should be checked after making ignition system adjustments. Also the exhaust control valve (if so equipped), crankcase ventilation system, and vacuum systems must be in good operating condition. Refer to the applicable Group in this manual for maintenance and repair procedures.

Initial Ignition Timing

Because of the high engine idle speeds required on exhaust emission control engines, precautions must be taken when setting the initial ignition timing to be sure that the distributor is not partially advanced. To be sure that no distributor advance is taking place, idle speed should be reduced to 600 rpm **after the vacuum hoses have been disconnected from the diaphragm unit and plugged.** Reset the idle to the specified rpm after adjusting the initial timing. Initial ignition timing and idle specifications for 1973 trucks are given in Specifications Booklet.

Breaker Point Alignment

The vented-type **pivoted** breaker points must be accurately aligned and strike squarely to assure normal breaker point life. Misalignment of these breaker point surfaces can cause premature wear, overheating and pitting.

1. Turn the cam so that the breaker points are closed and check the alignment of the points (Fig. 13).

If the distributor is in the engine, close the points by proceeding as follows:

With the ignition switch off and the primary wire disconnected from the coil, crank the engine with an auxiliary starter switch.

2. Using the tool shown and **exerting very light pressure,** align the breaker points to make full face contact by bending the stationary breaker point bracket (Figs. 14 and 15). **Do not bend the breaker arm.**
3. After the breaker points have been properly aligned, adjust the breaker point gap or dwell to specification.

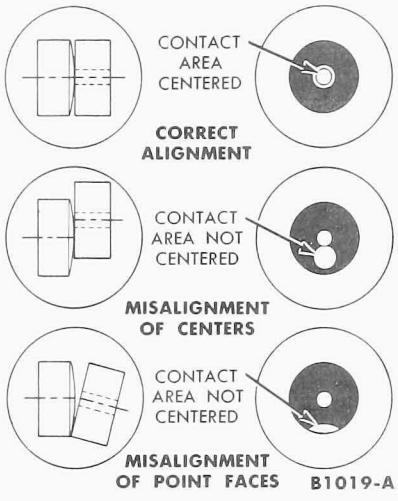

FIG. 13 Checking Pivoted Breaker Point Alignment

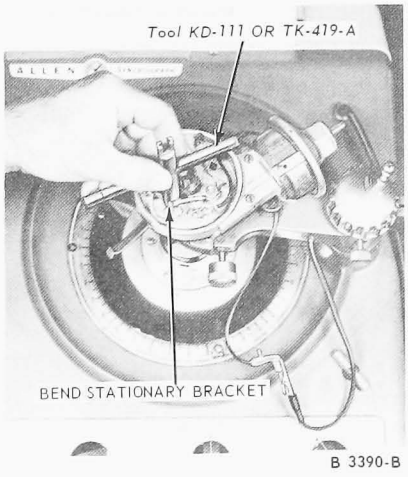

FIG. 14 Aligning Breaker Points

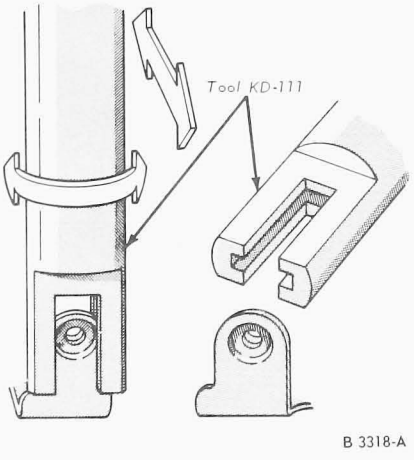

FIG. 15 Using Alignment Tool

Breaker Point Gap Adjustment

A scope, a dwell meter, or a feeler gauge can be used to check the gap of new breaker points.

A scope or a dwell meter should be used to check the gap of used breaker points. Due to the roughness of used points, it is not advisable to use a feeler gauge to check the gap.

To check and adjust the breaker points with a feeler gauge:

1. Check and adjust the breaker point alignment.
2. Rotate the distributor until the rubbing block rests on the peak of a cam lobe.

If the distributor is in the engine, place the rubbing block on the peak of the cam by proceeding as follows:

Crank the engine with an auxiliary starter switch until the breaker point rubbing block is on the highpoint of a cam lobe. Insert the correct blade of a clean feeler gauge between the breaker points (Fig. 16). Adjust the points to the correct gap and tighten the screws.

Apply a light film of distributor cam lubricant (C4AZ-19D530-A) to the cam when new points are installed. **Do not use engine oil to lubricate the distributor cam.**

Set the ignition timing.

If a scope or a dwell meter is used to adjust new points, be sure the points are in proper alignment. Also, set the contact dwell to the low setting.

To check and adjust the breaker points with a scope, refer to the scope manufacturer's instructions.

To check and adjust the breaker points with a dwell meter, refer to Distributor Tests—Rotunda ARE-27-55 Dwell Tester.

Breaker Point Spring Tension Adjustment

Correct breaker point spring tension is essential to proper engine operation and normal breaker point life. If the spring tension is too great, rapid wear of the breaker arm rubbing block will result, causing the breaker point gap to close up and retard the spark timing. If the spring tension is too weak, the breaker arm will flutter at high engine rpm resulting in an engine miss.

To check the spring tension on the breaker points, place the hooked end of the spring tension gauge over the movable breaker point. Pull the gauge at a right angle (90 degrees) to the movable arm until the breaker points just start to open (Fig. 17). If the tension is not within specifications, adjust the spring tension.

To adjust the spring tension (Fig. 18):

1. Disconnect the primary lead wire and the condenser lead.
2. Loosen the nut holding the spring in position. **Move the spring toward the breaker arm pivot to decrease tension and in the opposite direction to increase tension.**
3. Tighten the lock nut; then check spring tension. Repeat the adjustment until the specified spring tension is obtained.
4. Install the primary lead wire and the condenser lead.

IGNITION TIMING

Timing Mark Locations

The timing marks and their locations are illustrated in Figs. 19, 20 and 21.

The timing mark on the 240 engine in the Econoline and the 240 and 300 engines in P-Series trucks is a machined groove on the flywheel (Standard Transmission) or a stamped line on the flexplate (Automatic Transmission). It is viewed through an opening in the engine rear cover plate (Fig. 21) on the lower left side of the engine. A rubber plug covers the opening to prevent the entrance of dust and dirt. Steel stamped degree marks ranging from 0 degree or top dead center (TDC) to 14 degrees, before top dead center (BTDC) are located at the edge of the opening.

When checking the timing, the timing mark on the flywheel (or flexplate) should be in line with the specified degree mark on the engine rear cover plate opening when the timing light flashes.

The procedure for checking and adjusting the ignition timing with a scope is given in Adjustments of this Part. To check and adjust the timing with a Rotunda 13-07 power timing light proceed as follows:

Initial Ignition Timing—All Except Econoline With 302 CID Engine

1. Clean and mark the timing marks with chalk on white paint.
2. Disconnect the vacuum line (single-diaphragm distributors) or vacuum lines (dual-diaphragm distributor), and plug the disconnected vacuum line(s).
3. Connect a timing light to a terminal of the No. 1 cylinder spark plug wire. Connect tachometer to the engine.
4. Start the engine and reduce the engine idle speed to 600 rpm to be sure that the centrifugal advance is not operating. Adjust the initial ignition timing to specifications by rotating the distributor in the proper direction.
5. Check the centrifugal advance for proper operation. Start the engine and accelerate it to approximately 2000 rpm. If the ignition timing advances, the centrifugal advance mechanism is functioning properly. Note the engine speed when the advance begins and the amount of advance. Stop the engine.
6. Unplug the vacuum line and connect it to the distributor vacuum advance unit (outer diaphragm on dual diaphragm distributors). Start the engine and accelerate it to approximately 2000 rpm. Note the engine speed when the advance begins and the amount of advance. Advance of the ignition timing should begin sooner and advance farther than when checking the centrifugal advance alone. Stop the engine.
7. Check the vacuum retard operation on dual-diaphragm distributors. Connect the intake manifold vacuum line to the inner (retard) diaphragm side of the vacuum advance. Reset the carburetor to normal idle speed. The initial timing should retard to approximately 6 degrees ATDC (See Specifications).
8. If the vacuum advance or vacuum retard (dual-diaphragm distributors) is not functioning properly (refer to steps 6 and 7 above), remove the distributor and check it on a distributor tester. Replace the dual-diaphragm unit if the retard portion is not to specification. The advance portion cannot be calibrated to specifications, if either of the diaphragms are leaking. Unplug and reconnect the distributor vacuum lines. Remove the timing light and tachometer.

Econoline-With 302 Engine

1. Working from the underside of the vehicle (Fig. 19), clean and mark the timing marks with chalk or white paint.
2. Connect a timing light to a terminal of the No. 1 cylinder spark plug wire. Connect an engine speed tachometer.
3. Disconnect the vacuum line (single-diaphragm distributors) or vacuum lines (dual-diaphragm distributor), and plug the disconnected vacuum line(s).
4. Start the engine and reduce the engine idle speed to 600 rpm to be sure that the centrifugal advance is not operating. Adjust the initial ignition timing to specifications by

FIG. 16 Adjusting New Breaker Point Gap

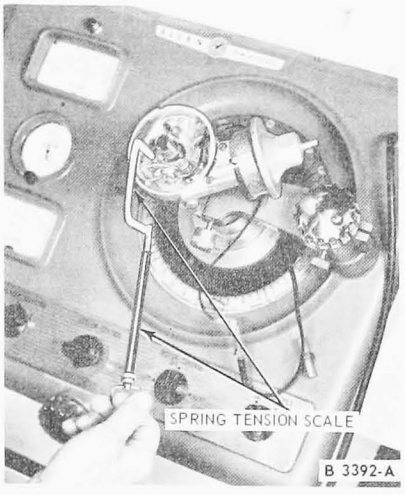

FIG. 17 Checking Breaker Point Spring Tension

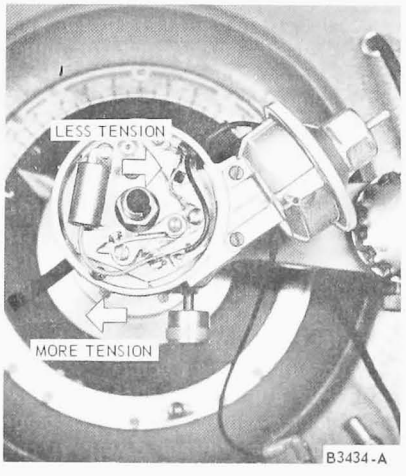

FIG. 18 Adjusting Breaker Point Spring Tension

having an assistant rotate the distributor in the proper direction. Tighten the distributor clamp hold-down screw after the correct setting has been obtained.

5. Check the centrifugal advance for proper operation. Start the engine and accelerate it to approximately 2000 rpm. If the ignition timing advances, the centrifugal advance mechanism is functioning properly. Note the engine speed when the advance begins and the amount of advance. Stop the engine.
6. Unplug the vacuum line and connect it to the distributor vacuum advance unit (outer diaphragm on dual diaphragm distributors). Start the engine and accelerate it to approximately 2000 rpm. Note the engine speed when the advance begins and the amount of advance. Advance of the ignition timing should begin sooner and advance farther than when checking the centrifugal advance alone. Stop the engine.
7. Check the vacuum retard operation on dual-diaphragm distributors. Connect the intake manifold vacuum line to the inner (retard) diaphragm side Connect the intake manifold vacuum line of the vacuum advance. Reset the carburetor to normal idle speed. The initial timing should retard to approximately—degrees ATDC (see Specifications). If the vacuum advance or vacuum retard (dual-diaphragm distributors) is not functioning properly (refer to steps 6 and 7 above), remove the distributor and check it on a distributor tester. Replace the dual-diaphragm unit if the retard portion is not to specification, the advance portion cannot be calibrated to specifications, if either of the diaphragms are leaking. Unplug and reconnect the distributor vacuum lines. Remove the timing light and tachometer. 240, and 300 EnginescP-Series Trucks

REMOVAL AND INSTALLATION

VACUUM HOSES

The basic vacuum hose connections for all distributor systems are shown in Fig. 22.

BREAKER POINTS AND/OR CONDENSER

Removal

1. Remove the distributor cap and the rotor.
2. Disconnect the primary and the condenser wires from the breaker point assembly.
3. Remove the breaker point assembly and condenser attaching screws. Lift the breaker point assembly and condenser out of the distributor.

Installation

1. Place the breaker point assembly and the condenser in position and install the attaching screws. Be sure to place the ground wire in the same location as the original installation.
2. Align and adjust the breaker points.
3. Connect the primary and condenser wires to the breaker points.
4. Install the rotor and the distributor cap.

SPARK PLUG WIRE

When removing the wires from the spark plugs, grasp, twist and pull the moulded cap with the hand only. Do not pull directly on the wire because the wire connection inside the cap may become separated or the boot may be damaged.

The ignition wiring installations are shown in Figs. 23 and 24.

Removal

1. Disconnect the wires from the spark plugs and distributor cap.
2. Pull the wires from the brackets on the valve rocker arm covers and remove the wires.
3. Remove the coil high tension lead.

Installation

1. Insert each wire in the proper socket of the distributor cap. Be sure the wires are forced all the way down

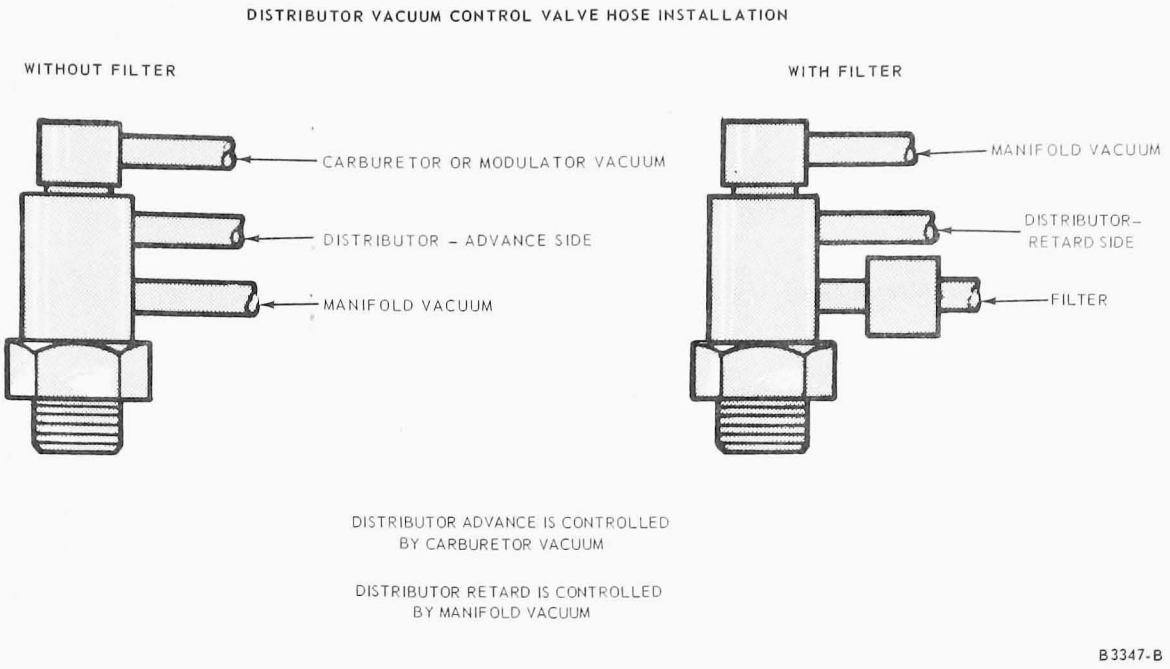

FIG. 22 Distributor Vacuum Hose Connections

into their sockets. The No. 1 socket is identified on the cap. On six-cyliinder engines, install the wires in a clockwise direction (Fig. 23). On V-8 engines except Super Duty, install the wires in a counterclockwise direction in the firing order (1-5-4-2-6-3-7-8) starting at the No. 1 socket. Cylinders are numbered from front to rear; right bank 1-2-3-4, left bank 5-6-7-8.

2. Remove the brackets from the old spark plug wire set and install them on the new set in the same relative position. Install the wires in the brackets on the valve rocker arm covers (Fig. 24). Connect the wires to the proper spark plugs. Install the coil high tension lead. Be sure the No. 7 spark plug wire is positioned in the bracket as shown in Fig. 24 (except Super Duty).
3. On Super Duty engines install the wires in a counterclockwise direction in the firing order (1-5-4-8-6-3-7-2) starting at the No. 1 socket. Note that the wires are positioned in the brackets in exact spark plug order on both banks for Super Duty engines.

SPARK PLUGS

Removal

1. Remove the wires from each spark plug by grasping, twisting and then pulling the moulded cap of the wire by hand only. Do not pull directly on the wire because the wire connection inside the cap may become separated or the weatherseal may be damaged.
2. After loosening each spark plug one or two turns, clean the area around each spark plug port with compressed air, then remove the spark plugs. If working on an Econoline or F-100 equipped with a 240 CID engine and air conditioning, it will be necessary to remove the No. 1 spark plug with special Proto Tool 5026-50. This tool can be purchased locally.

After cleaning, dress the electrodes with a small file to obtain flat parallel surfaces on both the center and side electrodes (Fig. 25). Set the spark plug gap to specifications by bending the ground electrode (Fig. 26). **All spark plugs new or used should have the gap checked and reset as required.**

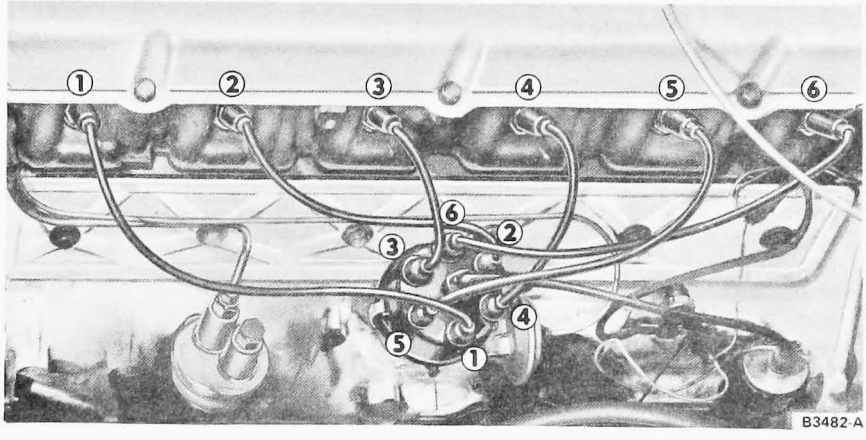

FIG. 23 Typical Ignition Wiring Six-Cylinder Engine

Installation

1. Install the spark plugs and torque each plug to specifications.
2. Connect the spark plug wires.

IGNITION RESISTOR WIRE

Due to its special resistance, under no circumstances should the resistor wire be spliced or replaced by any wire other than the service resistor wire. Do not coil or loop the surplus wire so that the coils or loops contact each other as excessive heat can be generated and cause the main wiring harness to overheat.

IGNITION RESISTANCE WIRE REPLACEMENT—ALL EXCEPT TRANSISTOR IGNITION

1. Disconnect the battery negative (ground) cable.
2. Working in the engine compartment, carefully drill a 1/2 inch hole thru the dash panel in the location shown in Fig. 27. Be careful not to contact the No. 14401 harness with the drill.
3. **Line Haul Only.** Working from inside the cab, locate the multiple (3 socket green) connector behind the lower instrument panel. Connect the bullet terminal end of the new D1HB-12250-AA resistor wire into one of the sockets (Fig. 28).
4. **City Delivery Only.** Working from inside the cab behind the upper instrument panel, remove the nut that secures the No. 16B red-green and the No. 904 green-red stripe wire to the right stud on the junction block (Fig. 3). Secure the eyelet terminal of the new D1EB-12250-AA resistance wire to the stud with the nut that was just removed.
5. Route the new resistance wire along the No. 14401 harness using the existing clips or electricians tape as shown in Figs. 27 and 29.
6. Insert the eyelet terminal of the new resistor wire through the 1/2 inch hole in the dash panel and install the grommet.
7. Remove the nut that secures the No. 16 pink wire to the left junction block stud and remove the pink wire from the stud. Cut the pink wire approximately 1 inch from the harness and tape the end of wire.
8. Attach the new resistor wire to the stud along with any other wires (except pink) that were disconnected and secure with the existing nut.
9. **Line Haul Only.** Cut the defective No. 16A pink resistance wire approximately 1 inch from the ignition switch connector and harness. Insulate the cut ends of wire with tape (Fig. 28).
10. Connect the battery negative (ground) cable to the battery.

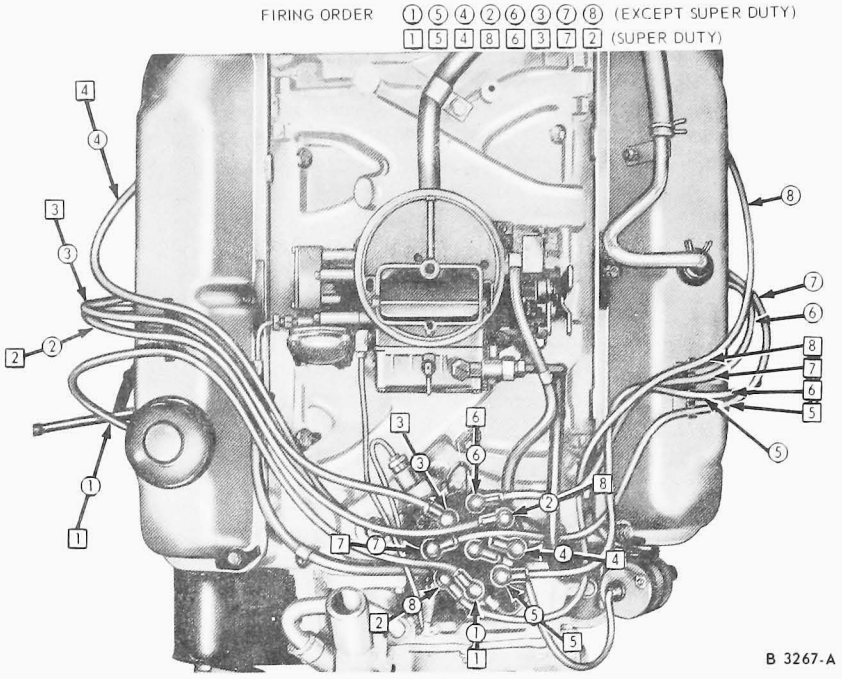

FIG. 24 Typical Ignition Wiring V-8 Engines

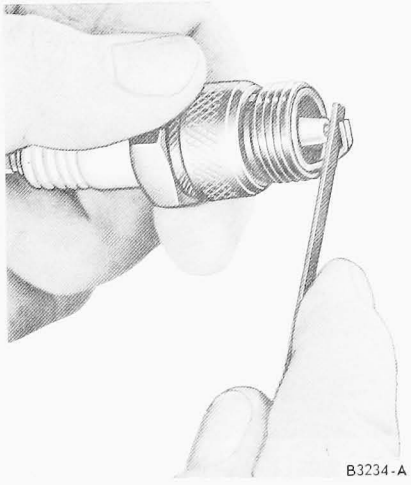

FIG. 25 Filing Spark Plug Electrode

Transistor Ignition—All Series

The resistance wire is connected to the green wire coming from the main disconnect and the green wire coming from the amplifier disconnect. It is connected to these green wires with quick disconnects.

1. Remove the malfunctioning resistance wire (black) from the quick disconnects.
2. Route the new wire along the wiring harness. Connect it to the quick disconnects.
3. Cut the old wire where it enters the wiring harness.

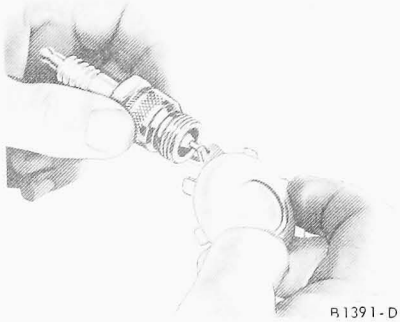

FIG. 26 Checking Spark Plug Gap

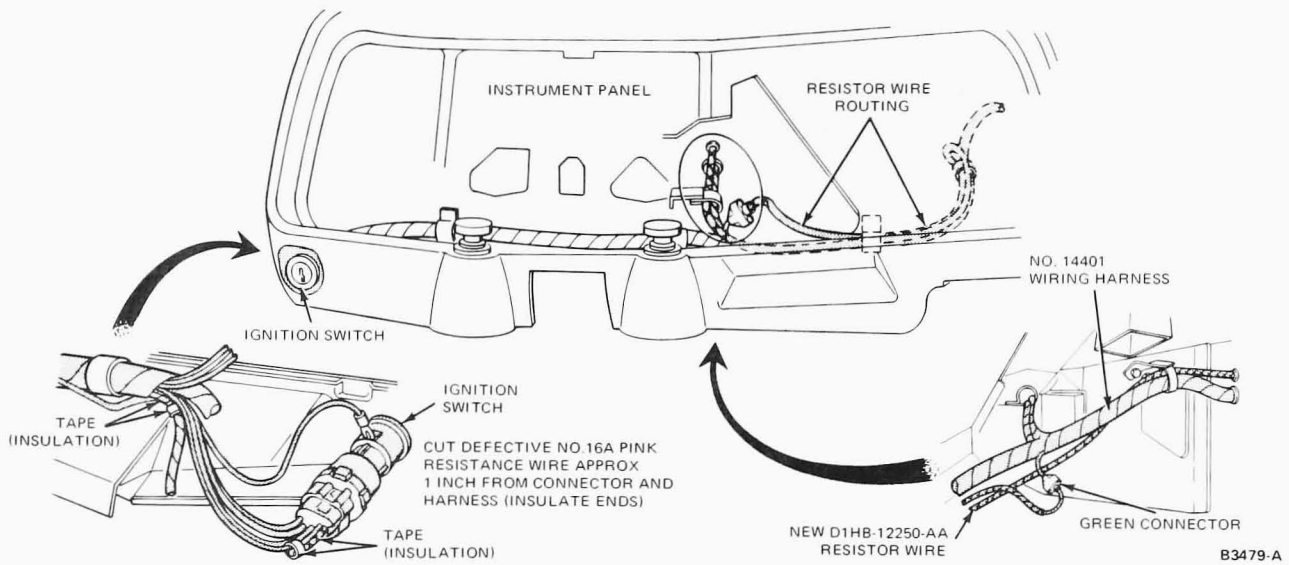

FIG. 28 Resistance Wire Connection Inside of Cab—Line Haul Vehicle

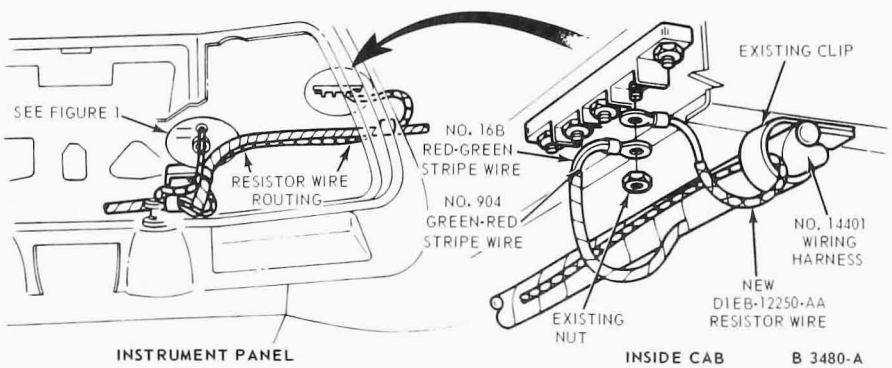

FIG. 29 Resistance Wire Connection Inside of Cab—City Delivery Vehicle

assembly (except the condenser, breaker point assembly, lubricating wick, vacuum diaphragm, distributor base oil seal and electrical wiring) in a mild cleaning solvent or mineral spirits. Do not use a harsh cleaning solution. Wipe all parts that can not be immersed in a solvent with a clean dry cloth.

After foreign deposits have been loosened by soaking, scrub the parts with a soft bristle brush. **Do not use a wire brush, file or other abrasive object.** Dry the parts with compressed air.

Inspect the distributor cam lobes for scoring and signs of wear. If any lobe is scored or worn, replace the cam assembly.

Inspect the breaker plate assembly for signs of distortion. Replace the breaker plate assembly if it is distorted.

The breaker point assembly and condenser (if so equipped) should be replaced whenever the distributor is overhauled.

Inspect all electrical wiring for fraying, breaks, etc., and replace any that are not in good condition.

Check the distributor base for cracks or other damage.

Check the diaphragm housing, bracket, and rod for damage. Test the vacuum hose connections, case, and diaphragm for leakage as explained under Distributor Tests. Replace all damaged parts.

The breaker point assembly consists of the stationary point bracket assembly, breaker arm and the primary wire terminal.

Breaker points should be inspected, cleaned and adjusted as necessary. Breaker points can be cleaned with chloroform and a stiff bristle brush. Replace the breaker point assembly if the contacts are badly burned or excessive metal transfer between the points is evident (Fig. 30). Metal transfer is considered excessive when it equals or exceeds the gap setting.

Distributor Cap

Clean the distributor cap with a soft bristle brush and mild cleaning solvent or mineral spirits. Dry the cap with compressed air. Inspect the cap for cracks, burned contacts. Permanent carbon tracks or dirt or corrosion in the sockets. Replace the cap if it is damaged as above.

Rotor

Clean the rotor with a soft bristle brush and mild cleaning solvent or mineral spirits. Dry the rotor with compressed air. Inspect the rotor for cracks or burning. Replace the rotor if it is cracked or burned.

SECONDARY WIRING

Wipe the wires with a damp cloth and check for fraying, breaks or cracked insulation. Inspect the terminals and weather seals for looseness or corrosion. Replace any wires that are not in good condition.

COIL

Wipe the coil with a damp cloth and check for any cracks or other damage.

CLEANING AND INSPECTION

SPARK PLUGS

Examine the firing ends of the spark plug, noting the type of deposits and the degree of electrode erosion. Refer to Fig. 31 for the various types of spark plug fouling and their causes.

Clean the plugs on a sand blast cleaner, following the manufacturer's instructions. **Do not prolong the use of the abrasive blast as it will erode the insulator and electrodes.**

After cleaning, examine the plug carefully for cracked or broken insulators, badly pitted electrodes, and other signs of malfunction. Replace as required.

DISTRIBUTORS

Soak all parts of the distributor

CONDITION	CAUSED BY
 BURNED	Incorrect voltage regulator setting. Radio condenser installed to the distributor side of the coil.
 EXCESSIVE METAL TRANSFER OR PITTING	Incorrect alignment. Incorrect voltage regulator setting. Radio condenser installed to the distributor side of the coil. Ignition condenser of improper capacity. Extended operation of the engine at speeds other than normal.

DESCRIPTION

IGNITION SYSTEM

The 1973 ignition systems continue to include all components required for the Imco exhaust emission control system.

All distributors are equipped with both vacuum and centrifugal advance units. The vacuum advance governs the ignition timing (spark advance) during low engine speeds (rpm) or low engine loadings. The centrifugal advance, in combination with the vacuum advance, controls the ignition timing at higher engine speeds or heavy engine loadings to provide the correct ignition timing for maximum engine performance. A dual diaphragm vacuum advance is used on some engines to provide additional ignition timing retard during engine idle operation.

The distributor cam on six cylinder engines rotate in a clockwise direction. To advance the timing, the distributor should be rotated in a counterclockwise direction. The distributor cam on V-8 engines rotate in a counterclockwise direction. To advance the timing, the distributor should be rotated in a clockwise direction.

VACUUM SINGLE ADVANCE UNIT

The distributor advance systems are independently operated. The centrifugal advance mechanism (Fig. 1), located below the stationary subplate assembly, has centrifugal weights that move inward or outward with changes in engine speed. As engine speed increases the centrifugal weights move ahead with respect to the distributor drive shaft. The rate of advance is controlled by calibrated weight springs.

The vacuum single advance has a spring loaded diaphragm connected to the breaker plate assembly. The diaphragm is moved against the spring pressure by vacuum pressures. When the vacuum increases, the diaphragm causes the movable breaker plate to pivot on the stationary sub-plate. The breaker point rubbing block, which is positioned on the opposite side of the cam from the pivot pin, then moves opposite to distributor rotation and advances the spark timing. As the movable breaker plate is rotated from retard position to full-advance position, the breaker point dwell will remain constant due to the breaker point rubbing block and the cam rotating on the same axes of the breaker plate and sub-plate.

DISTRIBUTOR DUAL-DIAPHRAGM VACUUM ADVANCE

The centrifugal advance unit is the same on dual-diaphragm vacuum advance distributors as on single diaphragm vacuum advance distributors. The dual-diaphragm unit consists of two independently operating diaphragms (Fig. 2). The outer (primary) diaphragm utilizes carburetor vacuum to advance ignition timing. The inner (secondary) diaphragm is actuated by intake manifold vacuum to provide additional ignition timing retard during periods of closed throttle idle, thereby assisting in the reduction of exhaust system hydrocarbon emission.

The outer diaphragm is coupled to the movable breaker plate much the same way as in single-diaphragm distributors. An increase in vacuum pressure moves the diaphragm against the advance diaphragm spring tension, causing the movable breaker plate to pivot opposite to distributor rotation. Thus, ignition timing is advanced, and this is calculated to occur during normal road-load operation, but not during deceleration or idle.

When intake manifold vacuum is applied to the inner diaphragm (retard), it moves inward toward the distributor (Fig. 2). This allows the advance diaphragm spring to move the advance diaphragm, causing the movable breaker plate to pivot in the same direction as distributor rotation. This retard of the ignition timing automatically occurs during engine idle or deceleration except when a distributor modulator is installed in the vacuum supply line.

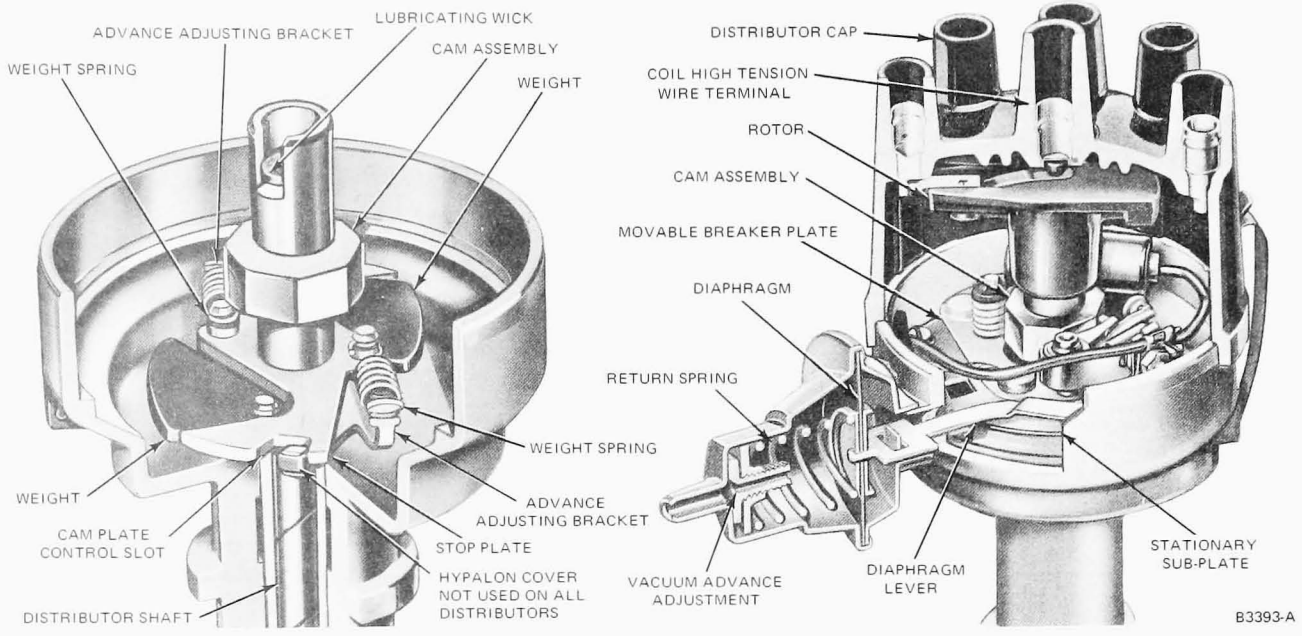

FIG. 1 Advance Mechanisms—Dual Advance Distributor With Single Diaphragm

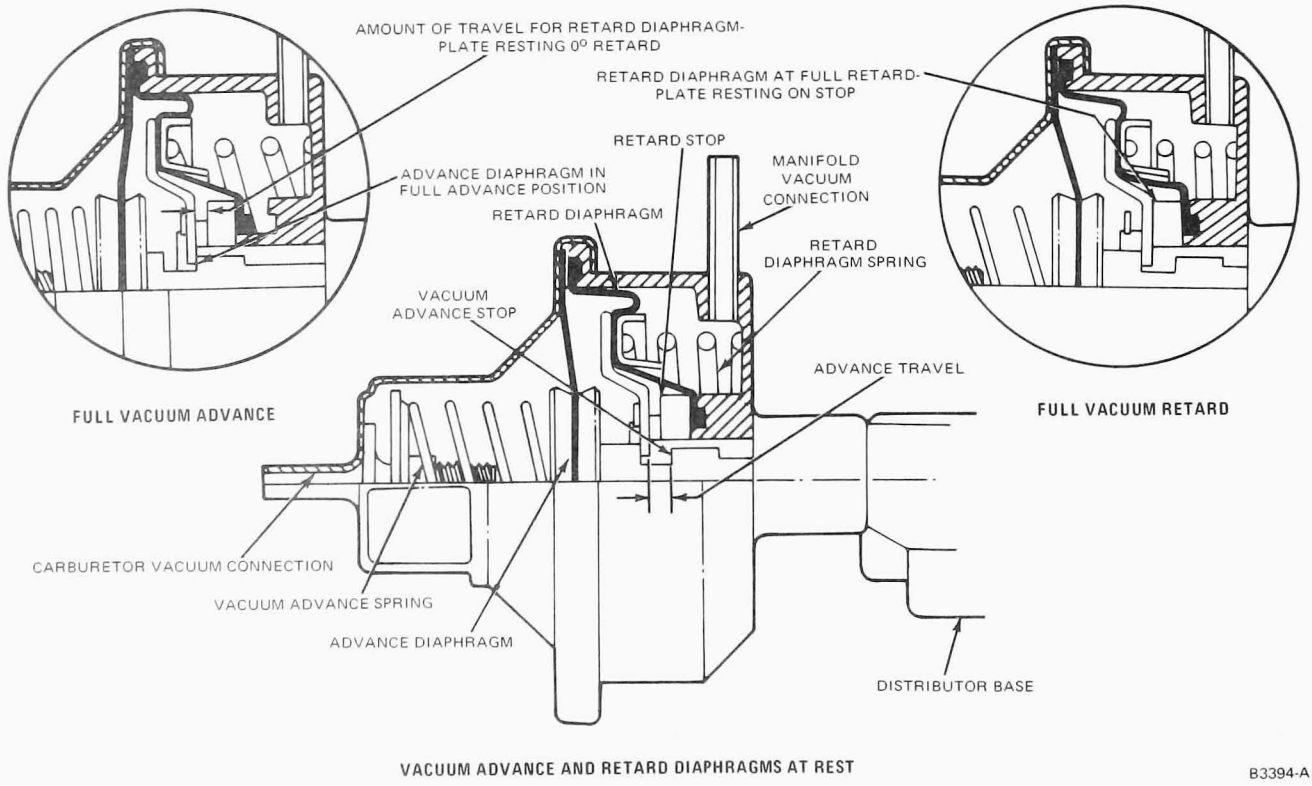

FIG. 2 Dual-Diaphragm Vacuum Advance Mechanism

REMOVAL AND INSTALLATION

BREAKER POINTS AND/OR CONDENSER

Removal and installation procedures for breaker points and condensers are covered in Part 23-01.

VACUUM ADVANCE UNIT—SINGLE AND DUAL DIAPHRAGM

Removal

1. Remove the distributor cap (dust cover, transistor ignition only) and rotor.
2. Disconnect the vacuum line(s).
3. Remove the spring clip that secures the diaphragm link to the movable breaker plate.
4. Remove the diaphragm unit attaching screws, and carefully remove the unit.

Installation

1. Position the diaphragm unit on the distributor and hook the diaphragm link in position.
2. Install the spring clip that secures the diaphragm link to the movable breaker plate. Install the diaphragm unit attaching screws.
3. Connect the vacuum line(s).
4. Install the dust cover (transistor ignition only), rotor and the distributor cap.

BREAKER PLATE AND SUB-PLATE

Refer to Figs. 3 and 4 for the correct location of parts.

Removal

1. Remove the distributor cap and rotor (if working on transistor ignition, remove the dust cover), radio supression cover (if so equipped).
2. Remove the breaker point assembly and the condenser. Remove the vacuum diaphragm.
3. Working from the inside of the distributor, pull the primary wire through the opening out of the distributor.
4. Remove the sub-plate attaching screws and lift the assembly from the distributor.

Installation

1. Place the breaker plate assembly in position in the distributor.
2. Install the sub-plate hold-down screws (the ground wire should be under the sub-plate hold-down screw from which it was removed) (Figs. 3 and 4).
3. Insert the primary wire in the distributor. Install the breaker points and the condenser. Connect the primary wire and the condenser wire to the breaker point terminal. Install the vacuum diaphragm.
4. Install the dust cap (transistor ignition only), rotor and the distributor cap.

CAM AND CENTRIFUGAL ADVANCE WEIGHTS

Removal

1. Remove the breaker plate and sub-plate from the distributor.
2. **Mark one of the distributor weight springs and its brackets. Also mark one of the weights and its pivot pin.**
3. Carefully unhook and remove the weight springs.
4. Lift the lubricating wick from the cam assembly. Remove the cam assembly retainer and lift the cam assembly off the distributor shaft. Remove the thrust washer.
5. Remove the weight retainers and lift the weights out of the distributor.

Installation

1. If the weights were removed, fill the grooves in the weight pivot pins with distributor cam lubricant (C4AZ-19D530-A).

Position the weights in the distributor **(the marked weight is placed on the marked pivot pin)** and install the weight retainers.

2. Place the thrust washer on the shaft.
3. Fill the grooves in the upper portion of the distributor shaft with distributor cam lubricant (C4AZ-19D530-A).
4. Install the cam assembly. **Be sure that the marked spring bracket on the cam assembly is near the marked spring bracket on the stop plate.**

If a new cam assembly is being installed, make sure that the cam is installed with the hypalon covered stop in the correct cam plate control slot. Some distributor stops will not be covered with the hypalon covering. The centrifugal advance range determines whether or not a hypalon cover is required. This can be done by measuring the length of the slot used on the old cam and by using the corresponding slot on the new cam. Some of the cams will have the size of the slot in degrees stamped near the slot. If the wrong slot is used, an incorrect maximum advance will be obtained.

Place a light film of distributor cam lubricant (C4AZ-19D530-A) on the distributor cam lobes. Install the retainer and the wick. Oil the wick with SAE-10W engine oil.

5. Install the weight springs. **Be sure that the marked spring is attached to the marked spring brackets.**
6. Install the plate assembly.
7. Install the diaphragm unit.

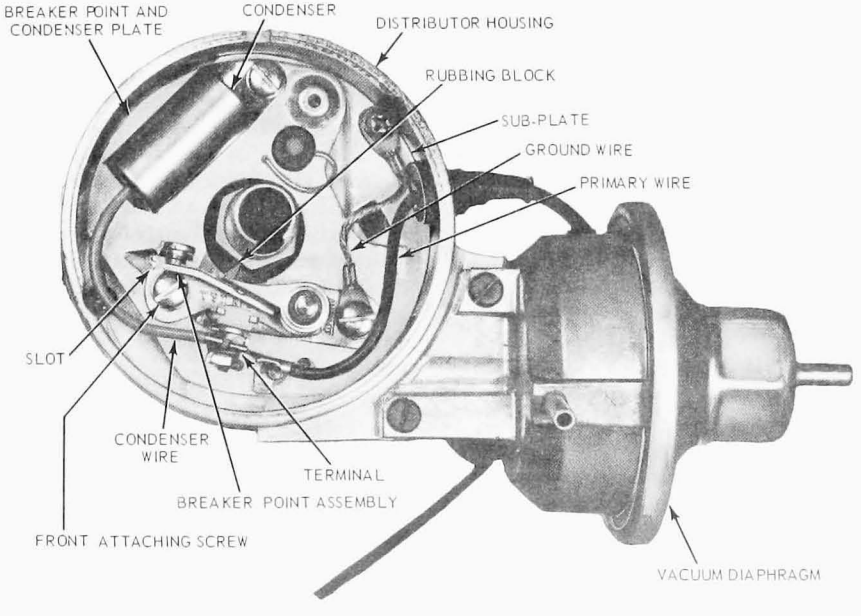

FIG. 3 Breaker Plate Installed—6-Cylinder Engine Dual Diaphragm Distributor

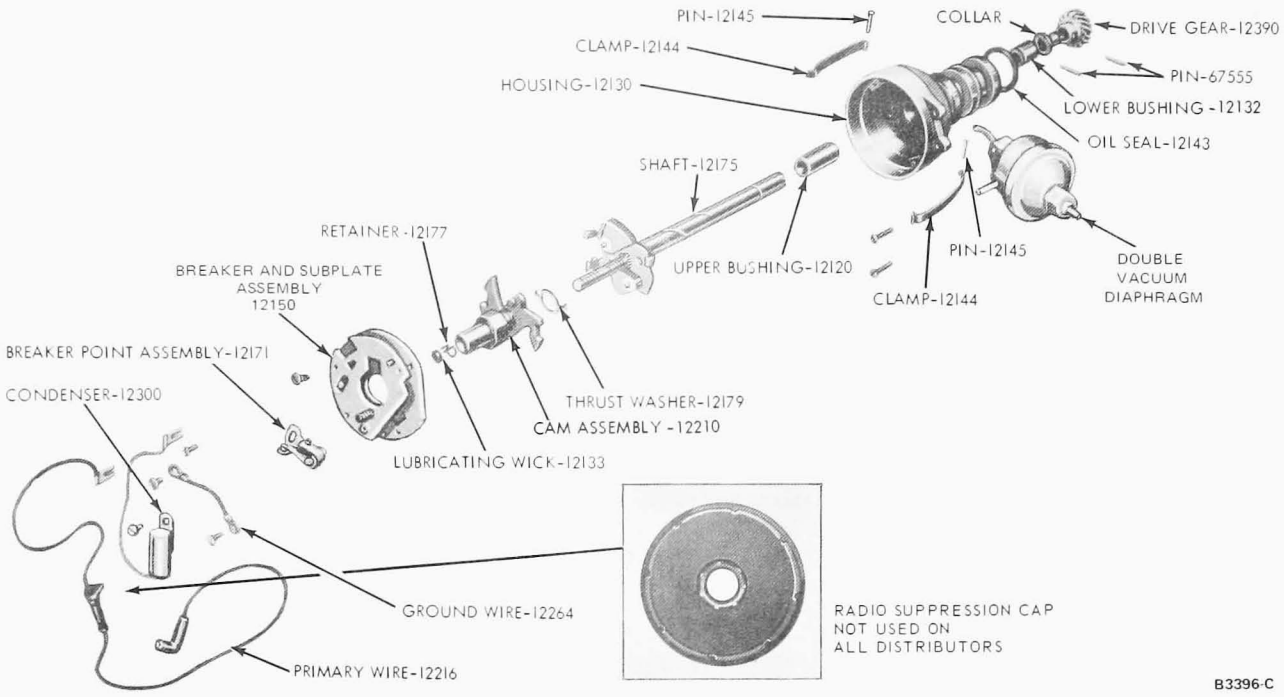

FIG. 4 Breaker Plate Installed—V-8 Engine single Diaphragm Distributor

8. Install the primary wire in the distributor. Connect the primary and condenser wires to the breaker point terminal.
9. Adjust the breaker point gap or dwell as required.

DISTRIBUTOR

Removal

1. Remove the air cleaner. Disconnect the primary wire from the coil.

Disconnect the vacuum advance line(s) at the distributor. Remove the distributor cap.

2. Scribe a mark on the distributor body and the cylinder block indicating the position of the body in the block, and scribe another mark on the distributor body indicating the position of the rotor. These marks can be used as guides when installing the distributor in a correctly timed engine.
3. Remove the distributor hold-down bolt and clamp. Lift the distributor out of the block.

Do not rotate the crankshaft while the distributor is removed, or it will be necessary to time the engine.

Installation

1. If the crankshaft was rotated while the distributor was removed from the engine, it will be necessary to time the engine. Rotate the crankshaft until No. 1 piston is on TDC after the compression stroke. Align the TDC mark on the timing pointer with the timing pin on the crankshaft damper. Position the distributor in the block with the rotor at the No. 1 firing position.

Make sure the oil pump intermediate shaft properly engages the distributor shaft. It may be necessary to crank the engine with the starter, after the distributor drive gear is partially engaged to engage the oil pump intermediate shaft.

Install, but do not tighten, the retaining clamp and bolt. Rotate the distributor to advance the timing to a point where the breaker points are just starting to open. Tighten the clamp.

2. If the crankshaft has not been moved, position the distributor in the block with the rotor aligned with the mark previously scribed on the distributor body and the marks on the distributor body and cylinder block in alignment.
3. Install the distributor cap.
4. Connect the primary wire to the coil.
5. Check the ignition timing with a timing light and adjust to specifications. Connect the vacuum line, and check the advance with the timing light when the engine is accelerated.
6. Install the air cleaner.

COMPONENT INDEX	Page	COMPONENT INDEX	Page
PORTED VACUUM SWITCH VALVE—PVS VALVE.		Installation	15-2
General Information	15-1	Removal	15-1
		Test	15-1

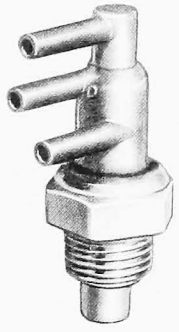
DESCRIPTION

GENERAL INFORMATION

This Part covers the various devices used to supplement the vacuum diaphragm controls installed on all current passenger car distributors. All of the devices regulate the distributor by changing the vacuum forces applied to the distributor diaphragm(s). These devices are used because of exhaust emission control requirements.

PORTED VACUUM SWITCH VALVE—PVS VALVE

The PVS valve (coolant temperature sensing valve, Figs. 1 and 2) is incorporated in the distributor vacuum advance supply line of certain engines to provide advanced ignition timing under prolonged idling conditions. The valve is installed in the coolant outlet elbow to sense engine coolant temperatures. Normally, the valve connects two ports, normal source vacuum at the carburetor and the distributor port. During periods of prolonged idle, should the engine temperature rise above normal, the valve closes the normal source vacuum port and connects the distributor port to the alternate source vacuum port. The advanced ignition timing causes an immediate increase in engine speed, which will continue until the engine temperature returns to normal.



B 3104-A

FIG. 1 Ported Vacuum Switch PVS Valve

PORTED VACUUM SWITCH VALVE TEST

The Ported Vacuum Switch Valve is shown in Figs. 1 and 2.

1. Make certain that all vacuum hoses are properly routed and installed.
2. Attach a tachometer to the engine.
3. Bring the engine up to operating temperature and be certain that the choke plate is in the vertical position. **Engine must not be overheated.**
4. Note the engine idle rpm with transmission in neutral and carburetor throttle in the curb idle position.
5. Disconnect the vacuum hose from the intake manifold at the temperature sensing valve and plug or clamp the hose.
6. Note engine idle rpm with the hose disconnected. If no change in idle speed, the valve is acceptable up to this point. If there is drop in idle speed of 100 rpm or more, the valve should be replaced.
7. Install vacuum line on manifold fitting; then verify that the all season cooling mixture is up to specifications, and that the correct radiator cap is installed.
8. Cover the radiator sufficiently to induce a high temperature condition.
9. Continue to run the engine until the red high temperature light comes on or the temperature indicated on the temperature gauge is at the high end of the band indicating an above normal temperature.

If the engine idle speed has by this time increased 100 rpm or more, the temperature sensing valve is satisfactory. If not, it should be replaced. Do not overheat the engine.

REMOVAL AND INSTALLATION

PORTED VACUUM SWITCH VALVE—PVS VALVE

Removal

1. Drain approximately one gallon of coolant from the radiator into a container.
2. Disconnect and tag the three vacuum hoses from the PVS valve.
3. Turn the PVS valve counterclockwise out of the thermostat housing.

Installation

1. Install the PVS valve in the thermostat housing.
2. Connect the three hoses to their respective ports.
3. Fill the cooling system with the specified coolant.

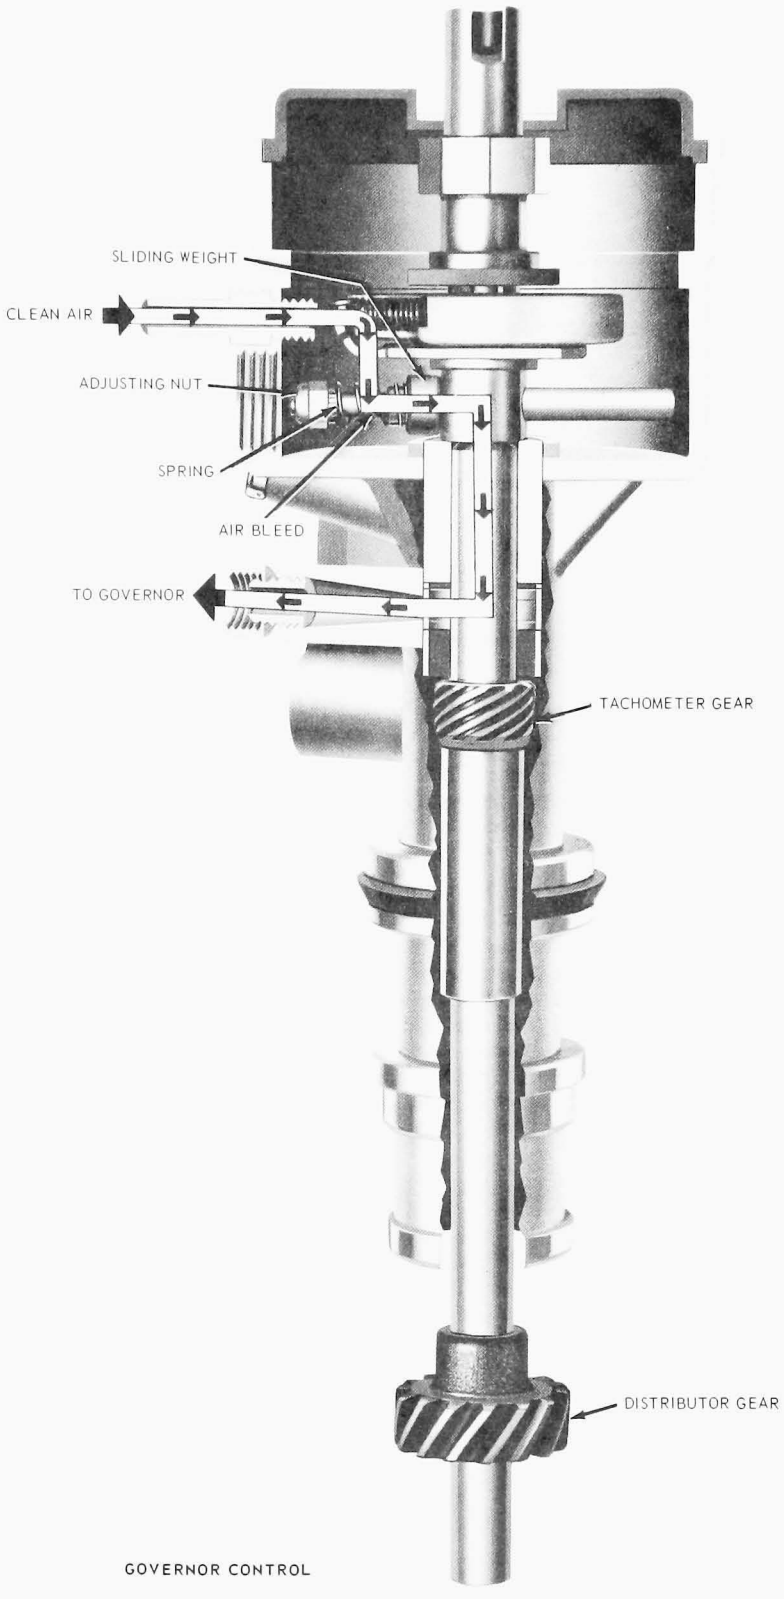
DESCRIPTION AND OPERATION

This dual advance distributor has two independently operated spark advance systems. A unique centrifugal spark advance and throttle governor control mechanism is located below the stationary sub-plate assembly (Fig. 1). A vacuum operated spark advance control diaphragm is located on the side of the distributor base (Fig. 1). Except for the built-in throttle governor valve mechanism and tachometer drive gearing, this distributor is similar in all respects to the dual-advance distributor described in Part 23-10.

The throttle governor operating principles are covered in Part 23-20, Governors.



B 3292-B

FIG. 1 Advance and Governor Control Mechanisms

DIAGNOSIS AND TESTING

DISTRIBUTOR

Testing instructions for this distributor are given in Part 23-01.

GOVERNOR CONTROL

Testing instructions for the governor control mechanism contained in this distributor are given in Part 23-20.

ADJUSTMENTS

DISTRIBUTOR

Adjustment instructions for this distributor are given in Part 23-01.

GOVERNOR CONTROL

Instructions for adjusting the vacuum governor control mechanism in this distributor are given in Part 23-20.

REMOVAL AND INSTALLATION

BREAKER POINT AND/OR CONDENSER

The replacement procedures for these units are covered in Part 23-01.

VACUUM DIAPHRAGM

Removal

1. Remove the distributor cap, rotor and dust cover.
2. Remove the vacuum line and fitting from the diaphragm.
3. Remove the spring clip that secures the diaphragm link to the movable breaker plate.
4. Remove the diaphragm attaching screws and slide the diaphragm (Fig. 2) out of the distributor.

Installation

1. Slide the diaphragm into the opening in the distributor and place the link in its position.
2. Install the spring clip that secures the diaphragm link to the movable breaker plate.
3. Install the diaphragm vacuum line and fitting.
4. Install the dust cover, rotor and distributor cap.

BREAKER PLATE AND/OR SUB-PLATE

Removal

1. Remove the distributor cap, rotor and dust cover.
2. Remove the breaker point assembly, condenser (if so equipped) and vacuum diaphragm (Fig. 2).
3. Disconnect the primary wire at the coil (conventional ignition system) or at the quick disconnect (transistor ignition system). Working from inside the distributor, pull the primary wire through the opening in the distributor.
4. Remove the spring clip, flat washer and spring washer attaching the breaker plate to the sub-plate.
5. Remove the sub-plate hold-down screws and lift both plates out of the distributor.

Installation

1. Place the breaker plate in position on the sub-plate.
2. Install the spring washer, flat washer and spring clip that attach the breaker plate to the sub-plate.
3. Install the sub-plate hold-down screws (the ground wire should be under the screw near the primary wire opening in the distributor).
4. Working from inside the distributor, push the primary wire through the opening in the distributor. Connect the primary wire to the coil (conventional ignition system) or the quick disconnect (transistor ignition system).
5. Install the breaker point assembly, condenser (if so equipped) and vacuum diaphragm.
6. Align and adjust the breaker points (Part 23-01).
7. Install the dust cover, rotor and distributor cap.

CAM AND CENTRIFUGAL ADVANCE MECHANISM

Removal

1. Remove the distributor cap, rotor and dust cover.
2. Disconnect the primary wire at the coil (conventional ignition system) or the quick disconnect (transistor ignition system). Working from inside the distributor, pull the primary wire through the opening in the distributor.

3. Remove the sub-plate hold-down screws and lift the breaker plate and sub-plate assembly from the distributor.
4. Lift the lubricating wick from the cam assembly. Remove the cam assembly retainer and lift the cam assembly and thrust washer off the distributor shaft.
5. **Mark one of the distributor weight springs. Place a mark on the bracket, weight and weight pivot that are assembled to the marked spring.**
6. Carefully unhook and remove the weight springs.
7. Lift the weights out of the distributor.

Installation

1. Fill the grooves in the weight pivot pin with distributor cam lubricant (C4AZ-19D530-A).
2. Position the weights in the distributor **(the marked weight is placed on the marked pivot pin).**
3. Install the weight springs (the marked spring is connected to the marked weight and bracket).
4. Place the thrust washer on the shaft.
5. Fill the grooves in the upper portion of the distributor shaft with distributor cam lubricant.
6. Install the cam assembly. Be sure that the slots in the cam engage the pins on the weights.
7. Install the cam retainer. Place a light film of distributor cam lubricant on the cam lobes. Install the wick in the cam assembly and oil the wick with SAE 10W engine oil.
8. Install the breaker plate and sub-plate assembly.
9. Working from inside the distributor, push the primary wire through the opening in the distributor. Connect the primary wire to the coil (conventional ignition system) or the quick disconnect (transistor ignition system).
10. Install the dust cover, rotor and distributor cap.

DISTRIBUTOR ASSEMBLY

Removal

1. Remove the air cleaner. Disconnect the primary wire at the coil (conventional ignition system) or the quick disconnect (transistor ignition system). Disconnect the vacuum advance rubber line, the governor air lines and the tachometer cable at the distributor, and remove the distributor cap.
2. Scribe a mark on the distributor body and cylinder block indicating the position of the body in the block, and scribe another mark on the distributor body indicating the position of the rotor. These marks can be used as guides when installing the distributor in a correctly timed engine.
3. Remove the distributor hold-down capscrew and clamp, then lift the distributor out of the block.

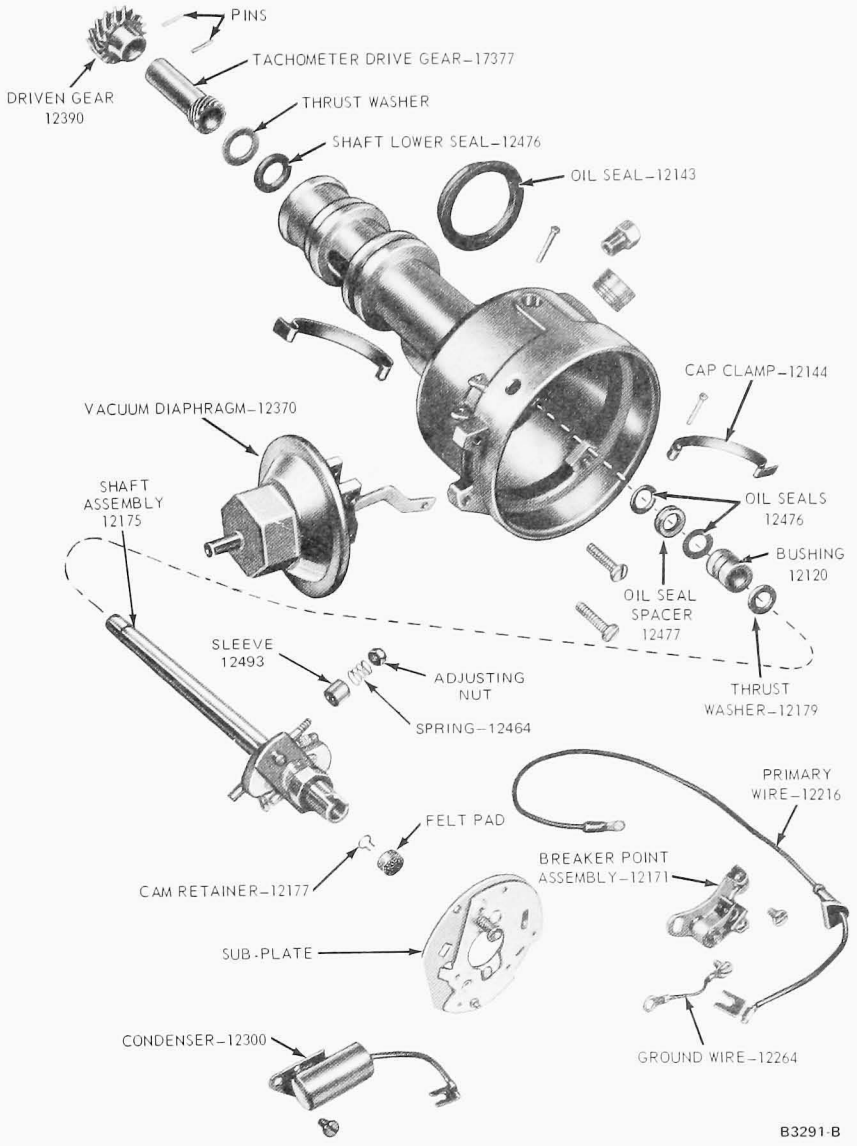


FIG. 2 Distributor Disassembled

Installation

1. If the crankshaft was rotated while the distributor was removed from the engine, it will be necessary to time the engine. Rotate the crankshaft until No. 1 piston is on TDC (after the compression stroke). Align the TDC mark on the crankshaft damper with the timing pointer. Position the distributor in the block with the rotor at the No. 1 firing position.

Make sure the oil pump intermediate shaft properly engages the distributor shaft. It may be necessary to crank the engine with the starter, after the distributor drive gear is partially engaged, in order to engage the oil pump intermediate shaft.

Install, but do not tighten, the retaining clamp and screw. Rotate the distributor body counterclockwise until the breaker points are just starting to open. Tighten the retaining clamp.

2. If the crankshaft has not been rotated, position the distributor in the block with rotor aligned with the mark previously scribed on the distributor body, and the marks on the distributor body and cylinder block in alignment. Install the retaining clamp.

3. Install the distributor cap.
4. Connect the primary wire to the coil (conventional ignition system) or the quick disconnect (transistor ignition system).
5. Connect the governor air lines and the tachometer cable to the distributor.
6. Install the air cleaner. Start the engine and check the ignition timing and adjust it if necessary (Part 23-01). Connect the vacuum line, and check the advance with the timing light when the engine is accelerated (Part 23-01).

DESCRIPTION AND OPERATION

VELOCITY GOVERNORS

Conventional Velocity Governor

The velocity governor (Fig. 1) is a single unit mounted between the carburetor and the intake manifold. There is no provision for repair of this governor. It should be replaced when damaged.

The governor is operated by a combination of manifold vacuum and the air flow past the governor valves. The governor throttle valves are offset in the throttle bore so that the combined force of manifold vacuum and the fuel air flow through the bores has greater effect on the larger, upstream area of the valves. This forces the throttle valves to move toward the closed position restricting the fuelair flow. The closing action of the throttle valves is opposed by the control spring. The control spring is attached to the throttle valve shaft cam. The cam provides a balance between the closing action of the throttle valves and the action of the control spring at all engine speeds.

Under operating conditions, the governor throttle valves do not close,

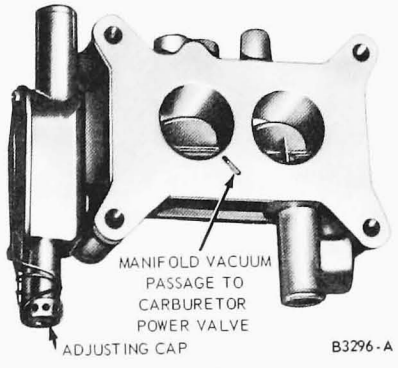

FIG. 1 Typical Velocity Governor

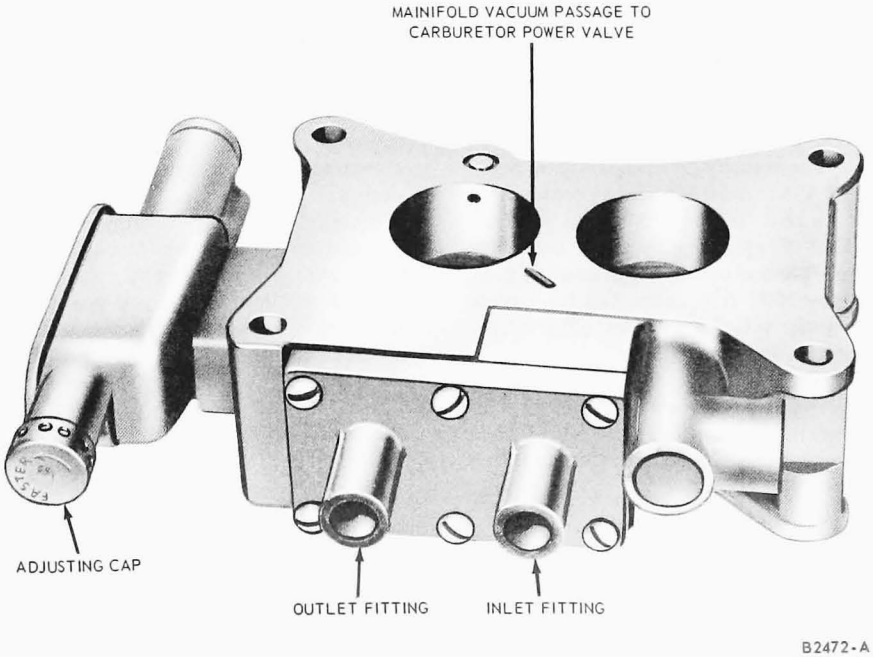

FIG. 2 Coolant Heated Velocity Governor

but remain open enough to allow the required quantity of the fuel-air mixture to flow into the manifold to maintain the governed engine speed.

To maintain the proper vacuum to the distributor, the governor has two interconnected vacuum transfer ports and a vacuum transfer plunger. When the governor throttle valves are forced toward the closed position, vacuum from the lower port is supplied to the distributor to maintain sufficient spark advance. When the governor throttle valves are open wide enough, the plunger shuts off the bottom port and the top port supplies vacuum to the carburetor distributor vacuum passage for sufficient vacuum to the distributor.

Coolant Heating Velocity Governor

The coolant heated velocity governor (Fig. 2) is used on the 360 and 390 truck engines with manual-shift transmissions. This governor has a coolant passage so that the governor can also be used as a coolant heated carburetor spacer. Otherwise, the description and operation of this governor is the same as the conventional velocity governor.

Compensating Governor 300 MD Engine

The characteristic of velocity-type governors is that the regulated engine speed increases in direct proportion to any increase in the altitude in which the engine is operated. This also causes a proportionate increase in the variance between regulated load and no-load settings. A normal sea level load setting of 3600 engine rpm becomes 4000 engine rpm at 5000 feet above sea level. A normal sea level no-load setting of 3900 engine rpm becomes 4500 engine rpm at 5000 feet above sea level. The 300 engine rpm variation at sea level becomes a 500 engine rpm variation at 5000 feet above sea level.

The velocity governor used on a 330 MD V-8 cam be adjusted to compensate for variations due to altitude. **Any 330 MD V-8 engine equipped with a velocity governor and operated consistently at or above 2000 feet above sea level must have the velocity governor adjusted for specific altitude.**

With the exception of the altitude compensating adjustment, the description and operation of this governor is the same as the conventional velocity governor.

VACUUM GOVERNOR

The throttle actuating mechanism on the carburetor (Fig. 3) has a diaphragm assembly, governor spring, and governor lever assembly. The spring and diaphragm are linked together by the governor lever which is attached to the carburetor primary throttle shaft. The controlling unit contains a centrifugally operated governor valve. The valve is driven by the distributor drive mechanism.

The operator controls the throttle plates in the usual manner below governing speeds through a clutch arrangement on the carburetor throttle body. When governing speed is reached, a combination of venturi and manifold vacuum acts on the governor diaphragm to close the throttle plates (Fig. 4). Two calibrated by-pass jets in the vacuum passages meter the vacuum from the venturi and the manifold to provide the correct balance for proper operation of the governor. At speeds below governing rpm., this vacuum is weakened by air from the governor valve so that premature governing action will not occur. Filtered air from the carburetor air cleaner enters the governor system through a passage in the carburetor to the controlling unit. A combination of vacuum from the venturi and manifold transmitted through the governor system passages on the carburetor, draws the air through the governor valve and back to the governor diaphragm on the carburetor.

In the controlling unit, centrifugal force acting on the governor valve, which has kept pace with engine speed, overcomes the tension of the valve spring and partially retards the flow of air to the throttle actuating mechanism when governing speed is reached.

The air flow is retarded by the valve sleeve being thrown outward by centrifugal force and thus partially closing the air inlet on the governor valve shaft.

The partial blocking of the air inlet reduces the amount of air bleeding through to the diaphragm on the carburetor, thus allowing manifold and venturi vacuum to operate the diaphragm. As the vacuum acting on the diaphragm becomes stronger, the diaphragm moves the governor lever against the tension of the governor spring to close the throttle plates. The governed engine speed is held for constant load by centrifugal force on the valve (in the ignition distributor) balanced against the tension of the valve spring. Any slight change in engine speed due to load restriction will cause the governor valve to react immediately, either increasing or decreasing the amount of air bleeding through the governor valve orifice. A change in amount of air bleed will, in turn, cause an instant response from the diaphragm to increase or decrease the throttle plate opening. When the accelerator is released, control is taken from the governor by the external throttle lever, and the return spring in the accelerator pedal linkage closes the throttle pedal to bring the engine to any desired lower speed.

MECHANICAL GOVERNOR

The governor is the mechanical flyweight type (Fig. 5). The flyweights are pivoted on the governor shaft. A direct mechanical linkage from the governor throttle control arm to the carburetor control arm limits carburetor action to the governor setting. As the engine speed increases, the rotation of the governor shaft increases. Centrifugal force causes the weights to move outward as the rotation of the governor shaft increases. However, a spring retards or limits the movement of the weights until the centrifugal force overcomes the spring tension. At this time the weights are forced outward closing the throttle plates through the linkage to the throttle shaft.

A clutch assembly, located on the side of the carburetor, connects the carburetor throttle shaft to the accelerator pedal linkage. When engine speed is below the governor full-load setting, the clutch is engaged. Once the full-load speed is attained, the main actuating lever on the governor and its linkage become the controlling factors and tend to close the throttle plates and disengage the clutch. At this point the maximum engine rpm is determined by the governor. When engine speed falls below the governor setting, the clutch re-engages, and the pedal accelerator linkage once again controls the rpm of the engine.

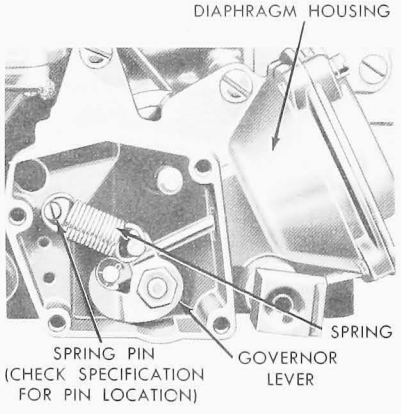

FIG. 3 Throttle Actuating Mechanism—Vacuum Governor

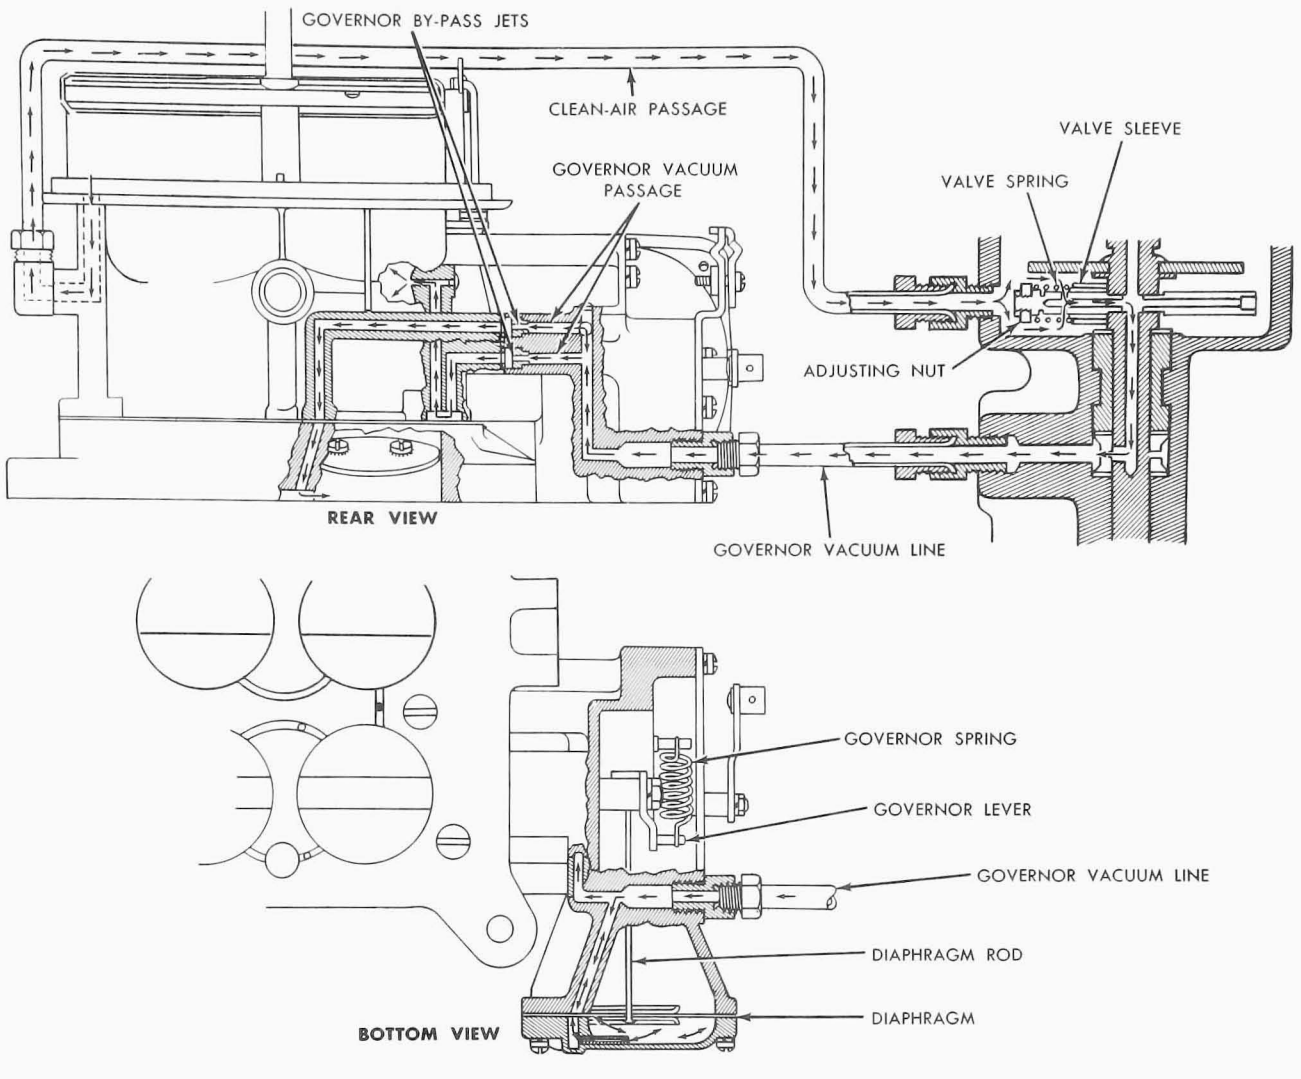

FIG. 4 Governor System

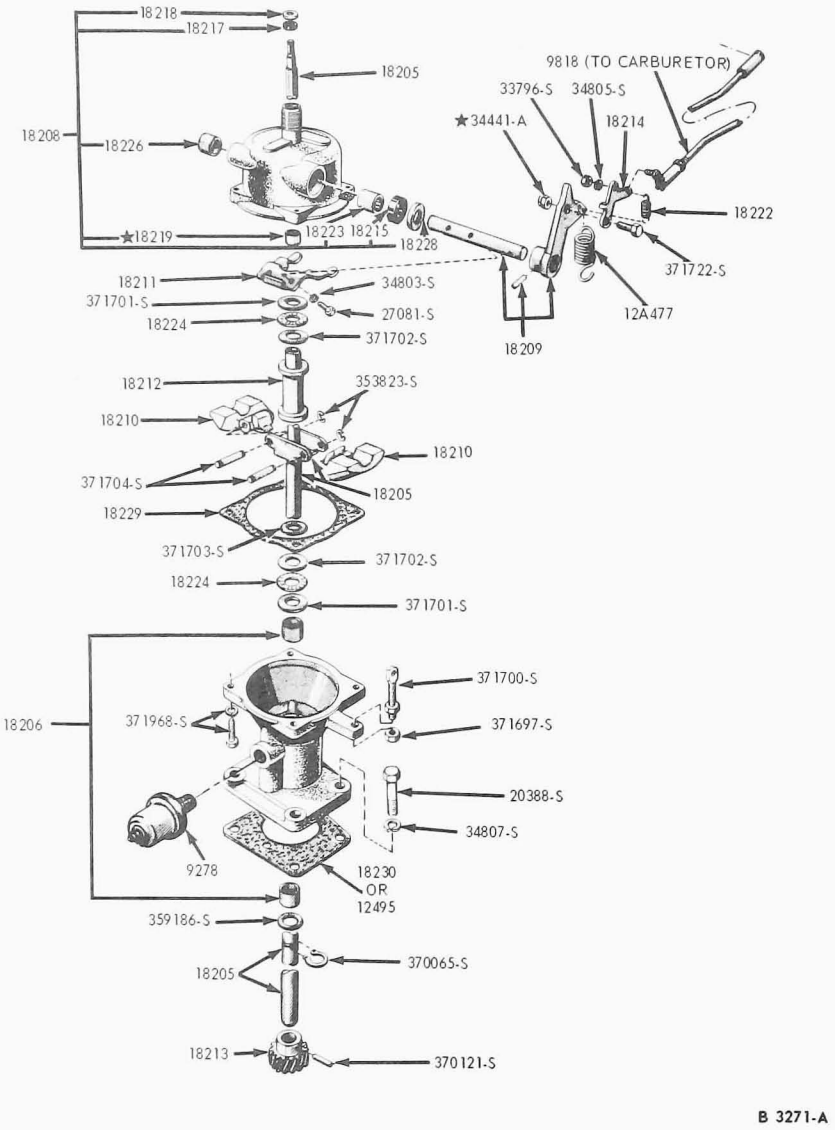

FIG. 5 Mechanical Governor

ADJUSTMENTS

VELOCITY GOVERNOR

Conventional and Coolant Heating Velocity Governors

Connect a tachometer to the engine. With the engine at normal operating temperature, operate the engine at wide open throttle and compare the rpm with the operating range of the governor. The operating range is stamped on the governor plate.

If governed speed is within range, stop the engine and remove the tachometer.

If adjustment is required or desires, remove the governor seal (Fig. 1). To increase rpm, turn the cap counterclockwise. To decrease rpm, turn the cap clockwise. When adjustment is complete, stop the engine, seal the cap, and remove the tachometer.

Compensating Governor

If the truck is going to be operated at a consistent altitude, or at varying altitudes above 2000 feet, adjust the governor by following the Constant Altitude Adjustment Procedure.

If the truck is going to be operated at varying altitudes adjust the governor by following the Varying Altitude Adjustment Procedure.

CONSTANT ALTITUDE ADJUSTMENT

1. Cut the governor seal wire and remove the adjusting cap (Fig. 1). **Do not rotate the adjusting cap during removal.**
2. Use a mirror and a light to observe the position of the slots in the adjusting bushing (Fig. 6).
3. Hold Tool T64T-12450-A in the proper position to engage the adjusting bushing slots (Fig. 6), and

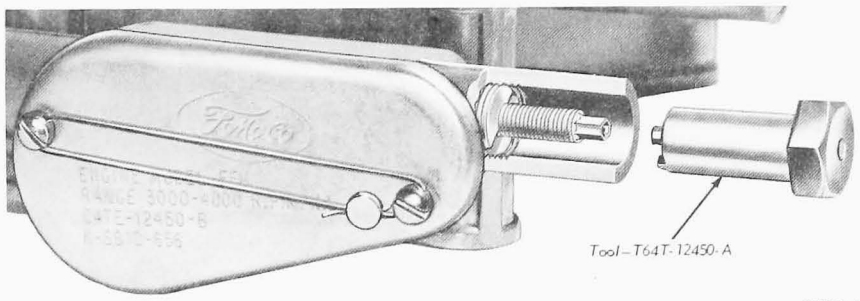
carefully insert the hex-shaped center post of the tool in the hex-head of the adjusting screw. Push the tool inward until the tangs on the tool engage the slots in the adjusting bushing. **If the tool will not engage in the adjusting bushing slots, note the position of the tool and rotate the tool slightly in either direction until engagement is achieved. If it is necessary to rotate the tool more than 1/6 turn (1 flat of the hex head) to accomplish engagement, rotate the tool back to its insertion position and pull the tool out. Rotate the tool 1/6 turn in the direction required to achieve engagement and re-insert it.**

4. The altitude adjustment table (Fig. 7) specified the amount from the factory setting that Tool T64T-12450-A should be rotated to adjust the velocity governor for altitude operation. For an increase in the average altitude of operation, rotate the tool the specified amount in the counterclockwise direction.
5. Remove the tool and install the adjusting cap. **Do not turn the adjusting cap.**
6. Install the tachometer and check and adjust the no-load setting of the governor. The no-load setting should be 3900 rpm at the trucks operating altitude. If the altitude adjustment was done properly, the load setting at the truck's operating altitude should be 3600 rpm. **If the governor is being adjusted at an altitude above the truck's anticipated operating altitude, the load and no-load speeds should be slightly above 3600 and 3900 rpm respectively. If the governor is being adjusted at an altitude below the truck's anticipated operating altitude, the load and no-load should be slightly below 3600 and 3900 rpm respectively.**

If the load rpm is below the specified rpm (3500 at sea level and 3600 at operating altitudes above 2000 feet), insert the tool by following step 3 and turn it counterclockwise. Remove the tool, insert the adjusting cap and adjust the no-load setting. Check the load setting and adjust again if necessary.

If the load rpm is above the specified rpm (3500 at sea level and 3600 at operating altitudes above 2000 feet), insert the tool by following step 3 and turn it clockwise. Remove the tool, insert the adjusting cap and adjust the no-load setting. Check the load setting and adjust again if necessary.

7. Remove the tool and install the adjusting cap.



B3297-A

FIG. 6 Altitude Compensation Adjustment

8. Seal the adjusting cap to the governor body (Fig. 1) using the service governor seal wire and lead seal.

VARYING ALTITUDE ADJUSTMENT

This adjustment is made on trucks that are operating between altitudes at or near sea level and altitudes above 2000 feet.

1. Adjust the governor to 3800 rpm (no-load) for sea level operation (this is only necessary if the governor has been adjusted after the truck has left the factory).
2. Using the adjusting cap only, adjust the no-load speed for 4100 rpm at the anticipated altitude by turning the adjustment cap 1/4 turn in the clockwise direction for each 1000 foot difference between the adjusting and maximum anticipated operating altitudes.

If the maximum operating altitude of the truck is lower than the altitude at which the adjustment is being made, adjust the no-load speed to 4100 rpm with the adjustment cap.

VACUUM GOVERNOR

1. Connect a tachometer to the engine.
2. Operate the engine until normal operating temperature has been reached.
3. Operate the engine at wide open throttle and note the engine speed registered.
4. Stop the engine and remove the adjusting hole plug from the controlling unit housing.
5. With the ignition switch off, crank the engine until the governor adjusting nut is aligned with the adjustment hole.
6. Turn the adjusting nut clockwise to increase speed and counterclockwise to decrease speed. One full turn of the adjusting nut will change top speed about 150 rpm.
7. Repeat the above procedure until the proper top speed is reached.
8. Install the adjusting hole plug and tighten it securely.
9. Attach a new locking wire and lead seal to the adjusting hole plug and the adjacent fin.

Average Operating Altitude—Feet	Amount of ① Tool Rotation
2000	1/3 turn (120°)
3000	1/2 turn (180°)
4000	2/3 turn (240°)
5000	5/6 turn (300°)
6000	1 turn (360°)

① 60° or 1/6 turn rotation is equivalent to one flat of the tool hex head.

CB1023-A

FIG. 7 Altitude Adjustment Table

MECHANICAL GOVERNOR

1. Disconnect the throttle control rod at the carburetor.
2. Loosen the top nut on the primary spring adjusting eye bolt.
3. Tighten the bottom nut finger tight, then turn it in two additional turns to pre-load the spring. Tighten the top nut.
4. Move the throttle to the wide open position and connect the governor throttle control rod to the carburetor control arm.
5. Adjust the governor throttle control rod so that the governor throttle control auxiliary lever is full forward. This is the wide open throttle position. Next, shorten the rod one full turn. This will position the throttle plates slightly off wide open position and will avoid

compression of the control rod linkage.

6. Check the accelerator linkage to be sure that wide open throttle position is achieved when the accelerator pedal is depressed to the floor. Be sure that the accelerator rod or cable is attached to the proper hole in the throttle lever.
7. Check the operation of the choke plate from the full open to the full closed position for proper adjustment and freedom of operation. **On a C-or W-Series truck, the choke plate will not close completely when the choke knob is pulled all the way out.**

If there is any bind in the choke cable on a C-or W-Series truck, examine the cable for sharp or reverse bends. Be sure the end of the cable is bent downward to prevent interference with the bottom of the air cleaner, as interference will restrict opening of the choke plate.

8. To adjust the speed, operate the engine (with the parking brake applied) until normal operating temperature has been reached. Depress the throttle to the full wide open position and adjust the speed by increasing the tension of the governor main spring to increase the rpm, and by decreasing the tension to decrease the rpm.

Sensitivity of the governor can be sharpened by installing the governor spring in the hole closest to the governor lever arm pivot. Adjust the governed speed after changing the spring position.

REMOVAL AND INSTALLATION

VELOCITY GOVERNOR

Removal

1. Remove the air cleaner.
2. On a six cylinder engine, cut the governor seal wire.
3. Remove the carburetor to governor vacuum line.
4. Remove the carburetor and gasket.
5. On a 360 or 390 V-8 engine with a manual-shift transmission, partially drain the radiator and remove the coolant hoses from the governor.
6. Remove the governor, spacer (if so equipped) and gaskets. Discard the gaskets.

Installation

1. Position a new gasket over the studs on the intake manifold.
2. Install the governor and gasket.
3. Install the spacer and gasket (if so equipped).
4. Install the carburetor.
5. On a 360 or 390 V-8 with a manual-shift transmission, connect the coolant hoses to the radiator and fill the radiator.
6. Install the governor to carburetor vacuum line.
7. On a six cylinder engine, install a new governor wire and seal.
8. Install the air cleaner.

VACUUM GOVERNOR

THROTTLE ACTUATING MECHANISM

Removal

1. Disconnect the lines at the governor unit on the carburetor.
2. Remove the choke control lever and the governor housing cover, the governor spring and spring pin, the governor lever nut and lock washer, and the governor housing to main body screws and lock washers. Mark the position of the spring pin for correct assembly.
3. Lift the governor housing off the throttle shaft and remove and discard the governor housing seal.

Installation

1. Position a new governor housing gasket on the main body. Install a new governor body seal on the governor housing, then slide the housing on the throttle shaft.
2. Insert the end of the throttle shaft into the governor lever and install the governor lever lock washer and nut.
3. Install the governor housing to main body lock washers and screws.
4. Install the governor housing cover and choke control lever.
5. Connect the governor lines.

CONTROLLING UNIT

Because the governor controlling unit is integral with the distributor, the removal, disassembly, assembly, and installation procedures are covered with the distributor.

MECHANICAL GOVERNOR

Removal

1. Disconnect the tachometer drive, the oil pressure sending unit wires, and the throttle control linkage at the governor.
2. Remove the governor assembly and gasket.

Installation

1. Using a new gasket, position the governor assembly in the cylinder block and install the washers and attaching nuts.
2. Connect the throttle control linkage, the tachometer drive, and the oil pressure sending unit wires. Adjust the governor.

DISASSEMBLY AND ASSEMBLY

VACUUM GOVERNOR

THROTTLE ACTUATING MECHANISM

Disassembly

1. Remove the diaphragm rod retainer and the governor lever.
2. Remove the governor line fitting, the by-pass jets, the diaphragm cover, and the diaphragm.
3. Remove the fast idle cam shaft retainer and slide the fast idle cam and shaft out of the housing.
4. Remove the cam plunger, plunger spring, and the fast idle pin.

Cleaning and Inspection. Clean all the metal parts in carburetor cleaner. Check the housing for cracks or stripped threads.

Assembly

Refer to Fig. 8 for the correct location of the parts.

1. Place the fast idle pin in position in the governor housing with the small

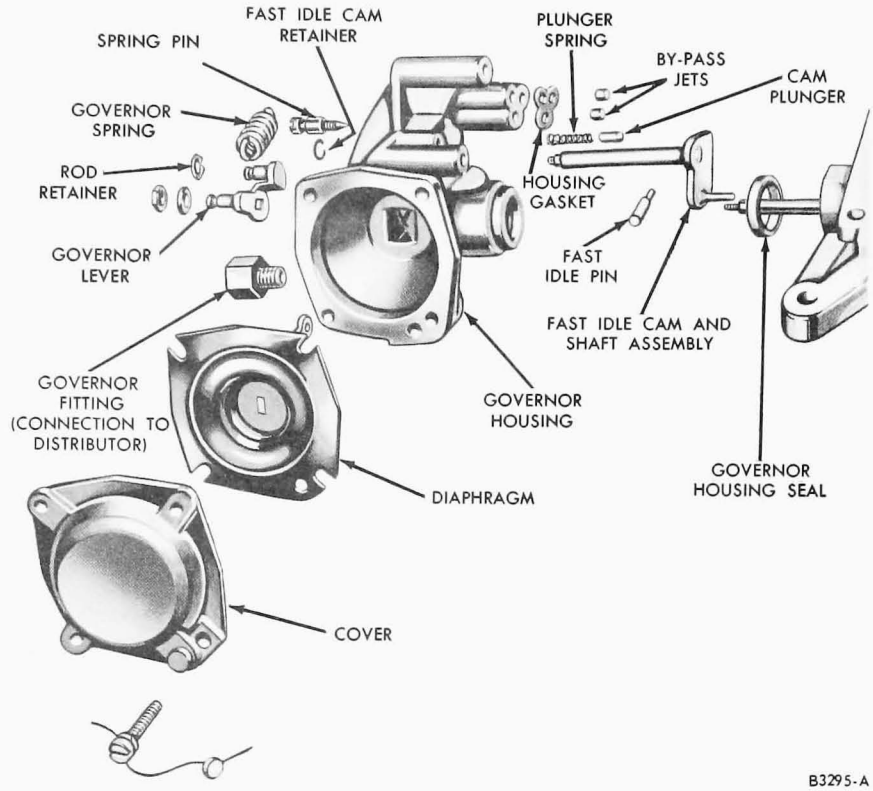


FIG. 8 Throttle Actuating Mechanism

end toward the throttle shaft.

2. Insert the fast idle cam plunger spring in the plunger and install the assembly in the governor housing.
3. Slide the fast idle cam and shaft in position and install the retainer.
4. Install the governor by-pass jets and the governor line fitting.
5. Install the governor spring pin in the same hole from which it was removed.
6. Position the governor diaphragm in the governor housing.
7. Install the cover, then install a new safety wire and seal.
8. Place the governor lever in the housing and insert the diaphragm rod on the smallest stud of the lever.
9. Install the rod retainer.

All engines incorporate a closed-type positive crankcase ventilation system and an exhaust emission system to control engine emissions within Government specifications.

To maintain the required exhaust emission levels, the carburetor must be kept in good operating condition and adjusted to specifications.

Additional engine performance checks are required to keep the exhaust emissions at the specified minimum pollutant level. Refer to the applicable owners manual for these performance checks and the recommended intervals.

This part covers general fuel system tests, adjustment and repair procedures. In addition, the cleaning and inspection procedures are covered.

For fuel system component removal, disassembly, assembly, installation and major repair procedures, refer to the pertinent part of this Group.

The carburetor identification tag is attached to the carburetor. The basic part number for all carburetors is 9510. To procure replacement parts, it is necessary to know the part number prefix and suffix and, in some instances, the design change code (Fig. 1).

Always refer to the Master Parts List for parts usage and interchangeability before replacing a carburetor or a component part of a carburetor.

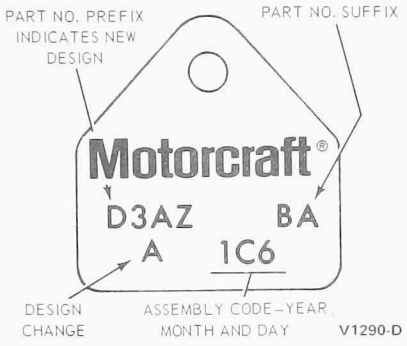

FIG. 1 Typical Carburetor Identification Tag

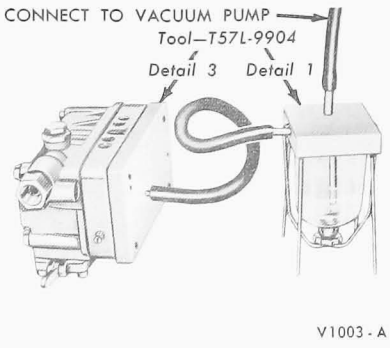

FIG. 3 Typical Holley Carburetor Power Valve Test

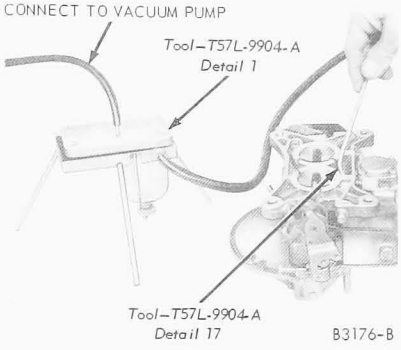

FIG. 2 Typical Motorcraft Carburetor Power Valve Test for Model 2100-D 2-V

TESTING

CARBURETOR TESTS

ACCELERATING PUMP DISCHARGE TEST

1. Remove the air cleaner.
2. Open the primary throttle plates and observe the fuel flow from the accelerating pump discharge nozzles. If the system is operating correctly, a quick steady stream of fuel will flow from the discharge nozzles.

POWER VALVE TESTS

A power valve test can be performed only on the Motorcraft Model 2100-D 2-V and Holley 2-or 4-V carburetors.

On the Carter Model YF 1-V, the power valve piston assembly is replaced only by Ford-authorized carburetor rebuilders.

A power valve must not be replaced unless it is leaking enough to cause an unadjustable rough engine idle condition. Fuel accumulation in the power valve cover does not necessarily indicate a non-functioning power valve. Fuel vapors will be drawn into the vacuum side of the power valve and condense during periods of deceleration. Leakage in the power valve area can be caused by an improperly tightened cover or leaking gaskets. Any gasket sealing qualities leakage must be corrected before the power valve is replaced.

If the power valve leakage is suspected, the following test procedure should be performed.

Motorcraft Model 2100-D 2-V Carburetor

1. Remove the carburetor from the intake manifold. Invert the carburetor.
2. Remove the glass bowl from the fixture (Fig. 2). Fill the bowl half-full of water. Install the bowl on the fixture.
3. Connect a line from the vacuum pump to the fitting on top of the fixture. Insert the large OD end of the wand into the tube and attach the other end of the tube to the fitting on the side of the fixture. Slip the rubber gasket (furnished with the tool) over the small OD end of the wand. Hold this end against the power valve vacuum pick-up port (Fig. 2).
4. Look for bubble formations in the water in the bowl. A continuous stream of bubbles indicates leakage through the power valve diaphragm or gasket, or the cover or gasket.

If leakage is encountered, the power valve, power valve gasket, cover, and cover gasket should be replaced one at a time with a new part and the test repeated until the source of leakage has

been found. If the source of leakage can not be found, the gasket seats are damaged and should be replaced.

A few bubbles may be noticed immediately upon attaching the vacuum line. The bubbling should stop within approximately 15 seconds or after the air has been removed from the system. If no bubbles are seen, the power valve, gaskets and cover are sealing properly.

Holley 2-V or 4-V Carburetor

1. Remove the fuel bowl and metering block (primary bowl and block on a 4-venturi carburetor) from the carburetor.
2. Install the fuel bowl, metering block, and gaskets on the adapter plate (Fig. 3). Be sure the fuel bowl screws are properly tightened.
3. Remove the glass bowl from the fixture and fill it half-full of water.
4. Install the bowl on the fixture.
5. Connect a line from a vacuum pump to the fitting on top of the fixture.
6. Connect a line from the adapter plate to the fitting on the side of the fixture.
7. Look for bubble formations in the water in the glass bowl. A continuous stream of bubbles indicates leakage through the power valve diaphragm or gasket. If leakage is encountered, install a new power valve and gasket and repeat the test. If leakage is still evident the gasket seat is damaged and the metering block should be replaced.

A few bubbles may be noticed immediately upon attaching the vacuum line. The bubbling should stop within approximately 15 seconds or after the air has been removed from the system. If no bubbles are seen, the power valve and gasket are sealing properly.

ADJUSTMENTS

CARBURETOR ADJUSTMENTS

SUPPLEMENTAL IDLE SPEED AND FUEL MIXTURE PROCEDURES

If a satisfactory idle condition is not obtained after performing the normal idle fuel settings, additional checks of engine systems must be performed.

1. The following items should be checked and, if required, corrected.
   a. Vacuum leak(s)-Refer to the Wiring and Vacuum Diagrams Manual (Form 7795P-73) for vacuum schematic diagrams and the location of the vacuum lines.
   b. Ignition system wiring continuity.
   c. Spark plugs.
   d. Distributor breaker point dwell angle.
   e. Distributor point condition.
   f. Initial ignition timing.

In certain instances, it may be possible that the idle condition is not as good as normally expected. It is suggested that the customer with a new vehicle be advised that the vehicle be driven 50 to 100 miles. Then, when the engine friction has been reduced, the idle condition should be improved. If, after this break-in period, the idle condition is believed to be unsatisfactory, readjust the engine idle speed to specification and observe for a satisfactory idle.

2. If the idle condition is not improved after the items in Step 1 have been checked, perform the following engine mechanical checks:
   a. Fuel level.
   b. Crankcase ventilation system.
   c. Valve clearance, using the collapsed tappet method on hydraulic valve lifters.
   d. Engine compression.
3. After verification of all engine systems has been made, there may be isolated cases where a satisfactory idle condition has not been obtained, due possible to a lean idle fuel mixture. If this condition is encountered, check the air-fuel ratio with the aid of an exhaust gas analyzer, and adjust the air-fuel ratio to specifications.

USE OF THE EXHAUST GAS ANALYZER

The use of the exhaust gas analyzer is recommended only after the Normal Fuel Setting Procedures and Additional Idle Speed and Fuel Mixture Procedures have been performed and the engine idle condition is still not satisfactory.

1. Connect a Rotunda Model BRE-42-721 Exhaust Gas Analyzer, JJRE-23 Exhaust Emission Analyzer or equivalent A/C-powered unit, in accordance with instructions provided by the manufacturer. **All exhaust gas analyzers must be checked for proper calibration.** Rotunda analyzers must have a **Certified Calibration Identification on the face of the instrument.**
2. Observe the reading obtained on the exhaust gas analyzer. **The analyzer reading must be taken with the air cleaner installed.** Refer to the specifications for the minimum air-fuel ratio or idle CO reading.
3. Turn the idle mixture adjusting screw(s), as required, within the range of the idle limiter until the specified air-fuel ratio or idle CO reading is obtained (on 2-and 4-barrel carburetors, turn the idle limiters an equal amount). **The analyzer reading must be obtained with the air cleaner installed.** Correct for any changes in engine idle speed immediately as the idle mixture screw(s) and limiters are turned. **Allow at least 10 seconds following each idle mixture screw or limiter adjustment for the analyzer reading to properly respond and stabilize.**

Verify the analyzer reading. Thermal conductivity exhaust gas analyzers will give an erroneously rich reading if the air-fuel mixture is extremely lean. To check for this condition, partially hand choke the carburetor, or rapidly open and close the throttle three or four times to enrich the air fuel mixture. The analyzer metering will reflect the momentary rich condition. Then it will deflect in the lean direction as the rich condition subsides, and will gradually return to a richer reading as the excessively lean air-fuel ratio or idle CO reading is produced. Vehicles with an automatic transmission must be in Neutral while this is being done.

4. If the air-fuel ratio or idle CO reading is to specifications, **and the various engine systems are functioning correctly,** no further adjustments should be made.

If the air-fuel ratio or idle CO reading is not to specifications, as shown by the analyzer reading, it may be corrected by altering the controlled limits of the carburetor idle fuel system. Refer to the procedures in Removal and Installation of Idle Limiter Caps.

REMOVAL AND INSTALLATION OF IDLE LIMITER CAPS

1. Remove the plastic limiter caps by cutting with side-cutter pliers and knife. After the cut is made, carefully pry the limiter apart. **On**

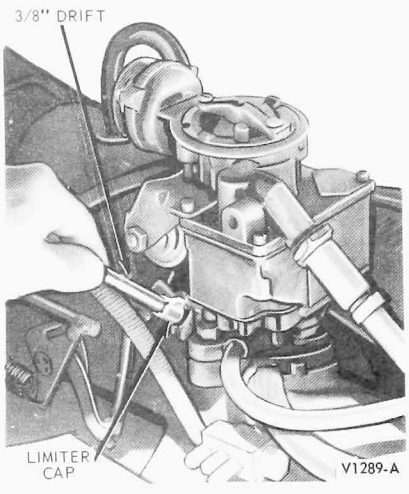

FIG. 4 Idle Limiter Installation—Carter Model YF 1-V

some carburetors, it may be necessary to remove the carburetor to remove the limiters.

On Holley 4-V carburetors with the limiters installed in the metering block, pry the limiters off with a screwdriver.

2. After the limiters are removed, set the carburetor to the correct air-fuel ratio or idle CO reading, using the exhaust gas analyzer.
3. When the air-fuel ratio or idle CO reading is within specifications, install colored plastic service limiter caps.

When installing a limiter cap, use care not to turn the idle mixture screw with the cap. Position the cap so that it is in the maximum counterclockwise position with the tab of the limiter against the stop on the carburetor.

The idle mixture adjusting screw will then be at the maximum allowable outward, or rich, setting.

To install the service limiter cap, use a straight, forward pushing force with thumb pressure or a 3/8-inch socket wrench extension (Fig. 4).

4. Recheck the air-fuel ratio or idle CO reading with the air cleaner installed, using the exhaust gas analyzer to make sure the limiter caps are properly installed. After the idle limiter has been reset and the air-fuel ratio and idle condition are satisfactory, stamp or scribe the letter **R** on the carburetor identification tag just above the name to indicate that the carburetor has been reworked.

CLEANING AND INSPECTION

CARBURETORS

Dirt, gum, water or carbon contamination in the carburetor or the exterior moving parts of the carburetor are often respondible for unsatisfactory performance. For this reason, efficient carburetion depends upon careful cleaning and inspection.

The cleaning and inspection of only those parts not included in the carburetor overhaul repair kit are covered here. All gaskets and parts included in the repair kit should be installed when the carburetor is assembled and the old gaskets and parts should be discarded.

Wash all parts except the rubber or solid nitrophyl carburetor float (if so equipped), the accelerating pump diaphragm, the power valve or power valve diaphragm, the fuel enrichment valve (4-V carburetor), the secondary throttle diaphragm (4-V carburetor), the governor diaphragm and the anti-stall dashpot diaphragm in clean commerical carburetor cleaning solvent. If a commercial solvent is not available, lacquer thinner or denatured alcohol may be used.

Rinse the parts in kerosene to remove all traces of the cleaning solvent, and then dry them with compressed air. Wipe all parts that can not be immersed in solvent with a clean, soft, dry cloth. Be sure all dirt, gum, carbon and other foreign matter are removed from all parts.

Check the metal float(s) for leaks by holding it under water that has been heated to just below the boiling point. Bubbles will appear if there is a leak. If a float leaks, replace it. Replace the float if the arm needle contact point is grooved. If the float(s) is serviceable, polish the needle contact surface of the arm with crocus cloth or steel wool. Replace the float shaft(s) if it is worn.

Force compressed air through all passages of the carburetor. **Do not use a wire brush to clean any parts or a drill or wire to clean out any openings or passages in the carburetor.** A drill or wire may enlarge the hole or passage, changing the calibration of the carburetor.

Check the choke shaft for grooves, wear, and excessive looseness or binding. Inspect the choke plate for nicked edges and for ease of operation. Free the shaft and plate, if necessary.

Check the throttle shaft(s) in its bore for binding. Check the throttle plate(s) for burrs which prevent proper closure.

Check the action of the poppet valves in the choke plate and the poppet valves in the air horn (Holley 4-V carburetor). Free them, if necessary.

Inspect the main body, throttle body and metering block (Holley carburetors) air horn, nozzle bars and booster venturi assemblies (2-V and 4-V carburetors), power valve cover, accelerating pump cover, and the secondary diaphragm housing (Holley 4-V carburetor) for cracks.

Replace all screws and nuts that have stripped threads. Replace all distorted or broken springs.

Inspect all gasket mating surfaces for nicks and burrs. Repair or replace any parts that have a damaged gasket surface.

On the Holley 2-V or 4-V carburetors, inspect the main and accelerating pump discharge nozzles and idle restrictions. If any of the openings are blocked, open them with compressed air.

On the Motorcraft 2-V carburetor, inspect the idle tubes in each nozzle bar assembly. If they are plugged, bent, or broken, replace the booster venturi and nozzle bar assembly.

Inspect the rubber boot of the anti-stall dashpot (if so equipped) for proper installation in the groove of the stem bushing. Check the stem movement for smooth operation. **Do not lubricate the stem. Replace the assembly if it is damaged.**

MECHANICAL FUEL PUMPS—GASOLINE ENGINES

On all fuel pumps, except the Carter permanently sealed type, clean the fuel pump body, valve housing and cover. If the fuel pump is equipped with an integral fuel filter, clean the filter housing and cover passages. Inspect the pump body, valve housing, cover, rocker arm, spring and pin for cracks or damage and replace them if necessary. If

the fuel valves are not serviceable and replacement is necessary replace the valve housing and valves as an assembly. Inspect the mounting flange for distortion. Remove the pump body or lap the distorted flange if necessary.

On Carter permanently sealed fuel pumps, clean the fuel pump with a cloth. Clean the integral filter housing in solvent. Inspect the fuel pumps for cracks or damage. Inspect the mounting flange for distortion. Lap the distorted flange, if necessary. Inspect the rocker arm spring, pin and the rocker arm for wear, cracks or damage. **The rocker arm spring, pin and the rocker arm are the only components on the permanently sealed fuel pumps that are replaceable. If any other fuel pump components are damaged beyond repair, replace the fuel pump.**

ELECTRIC FUEL PUMP—GASOLINE ENGINES

The electric fuel pump is replaced as an assembly and should not be disassembled for cleaning or inspection purposes. Refer to Wiring Diagram Manual, Form 7795P-73 for schematics and locations of wiring harnesses and related parts.

DESCRIPTION

The model YF 1-V carburetor is made up of three main assemblies: the air horn, the main body, and throttle body (Figs. 1 and 2).

The air horn, which serves as the main body cover, contains the automatic choke thermostatic control (on most models), the choke plate, internal fuel bowl vent, fuel inlet fitting, inlet needle and seat and the float and lever assembly. The anti-stall dashpot or solenoid throttle positioner (if equipped) is bracket-mounted to the air horn.

Medium-Duty vehicles in the F-B- and LN-500 Series with either a 240 or 300 CID engine and the Medium-Duty vehicles in the P-350, 400 and 500 Series with a 240 CID engine are equipped with a manual choke. All others use a vacuum piston-type automatic choke.

The main body contains the accelerator pump assembly, metering rod jet, low-speed jet, accelerator pump check ball and weight, an anti-percolator bleed and the main discharge nozzle.

The throttle body contains the throttle plate, throttle shaft and lever and idle mixture adjusting screw with a plastic limiter cap and choke connector rod (manual choke carburetors).

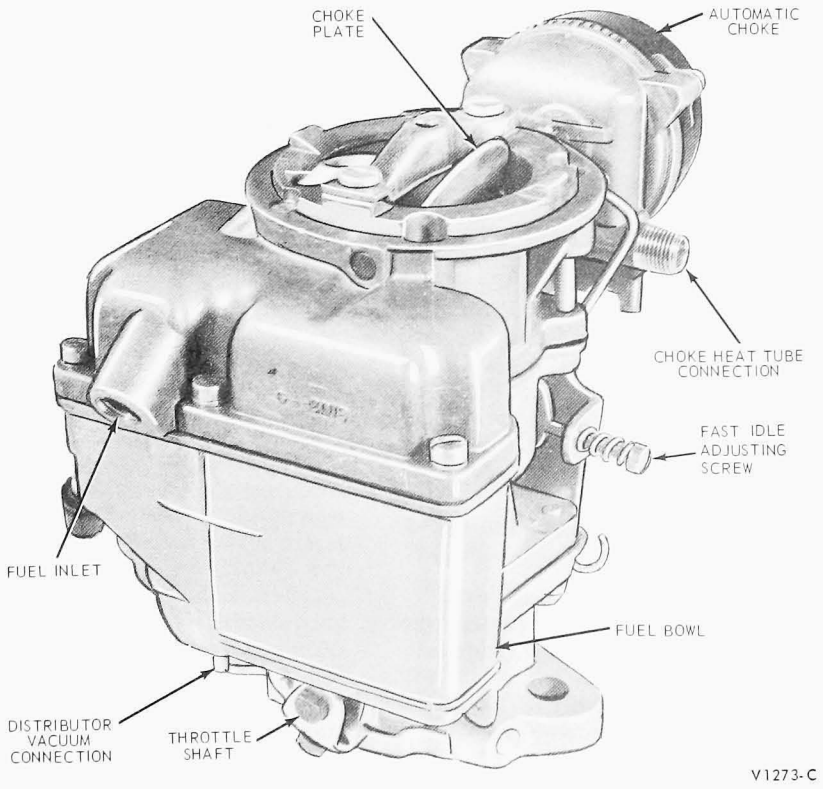

FIG. 1 Model YF 1-V Carburetor—Left Front View

The Model YF 1-V carburetors used on the F-100 4 x 2 and 4 x 4 and E-100, 200 and 300 vehicles equipped with a 240 CID Six are equipped with a solenoid throttle positioner (Fig. 3). The solenoid reduces the curb idle rpm by allowing the throttle plate to close farther than the normal curb idle position when the ignition is turned off.

The engine speed is regulated and controlled by a proportion a fuel and air delivered to the cylinders for all engine operating conditions. Operation is based on the principle of pressure differences.

Air is drawn into the carburetor air horn by manifold vacuum. As the air passes through the carburetor on the way to enter the cylinders, low pressure is created at the fuel discharge outlets of the carburetor. The fuel bowl is vented to the carburetor air horn. The high air pressure exerted on the fuel in the bowl forces the fuel to travel up through the fuel discharge channels and out into the air stream passing through the carburetor. The fuel and air is mixed at this point and distributed into the engine cylinders for combustion.

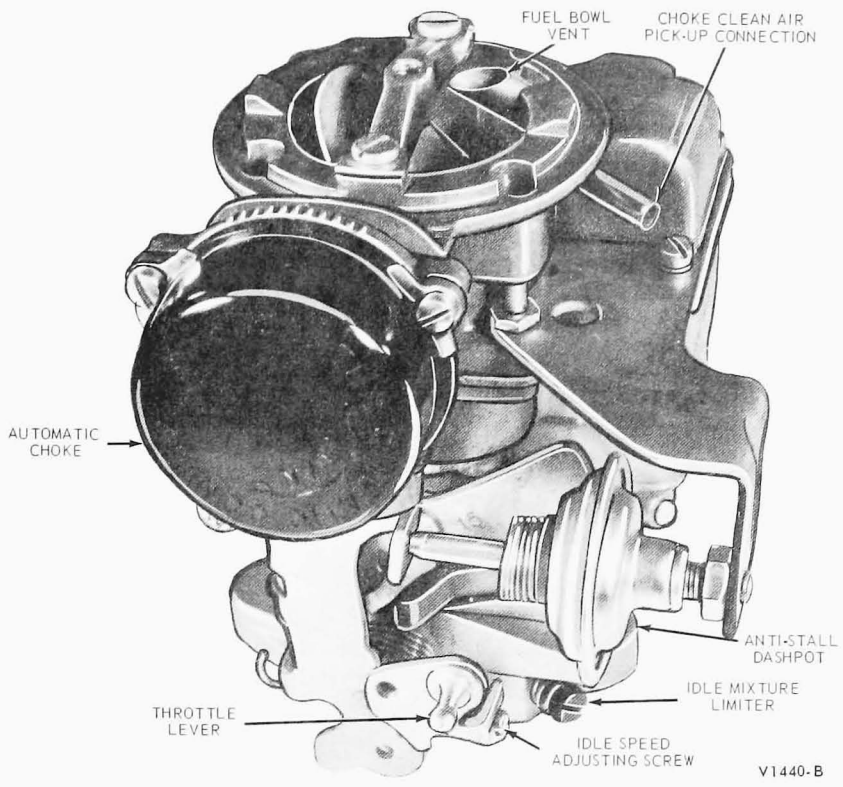

FIG. 2 Model YF 1-V Carburetor

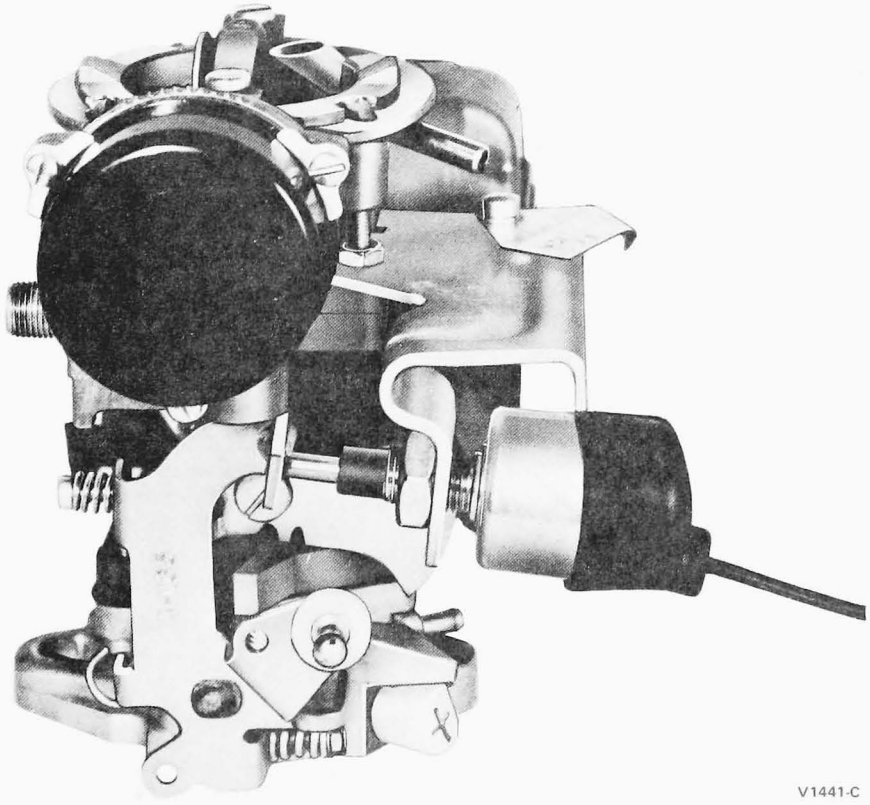

FIG. 3 Model YF Carburetor Equipped with Throttle Solenoid Positioner

ADJUSTMENTS

All carburetors are equipped with idle fuel mixture adjusting limiters. The limiters control the maximum idle fuel richness and prevent overly rich idle adjustments.

The external-type plastic idle limiter cap is installed on the head of the idle fuel mixture adjusting screw (Fig. 4). Any idle fuel mixture adjustment made on carburetors having this type of limiter must be within the range of the idle adjusting limiter. **Under no circumstances are the idle adjusting limiters or the limiter stops on the carburetor to be mutilated or deformed to render the limiter inoperative.**

A satisfactory idle should be obtainable within the range of the idle adjusting limiters, providing all other engine systems are operating within specifications.

Following are the normal procedures necessary to properly adjust the engine idle speed and fuel mixture. The specific operations should be followed in the sequence given whenever the idle speed or idle fuel adjustments are made.

In isolated cases a satisfactory idle condition may not be achieved by performing the normal procedures. If this occurs, refer to Supplemental Idle Speed and Fuel Mixture Procedures (Part 24-01).

NORMAL IDLE FUEL SETTINGS

ENGINE OFF

1. Set the idle fuel mixture screw and limiter cap to the full counterclockwise position of the limiter cap.
2. Back off the idle speed adjusting screw until the throttle plate seats in the throttle bore.
3. Be sure the dashpot or solenoid (if so equipped) plunger is not interfering with the throttle lever.

It may be necessary to loosen the dashpot to allow the throttle plate to seat in the throttle bore.

4. Turn the idle speed adjusting screw inward until it just makes the contact with the screw stop on the throttle shaft and lever assembly, and then turn the screw inward 1 1/2 turns to establish a preliminary idle speed adjustment (Fig. 5).

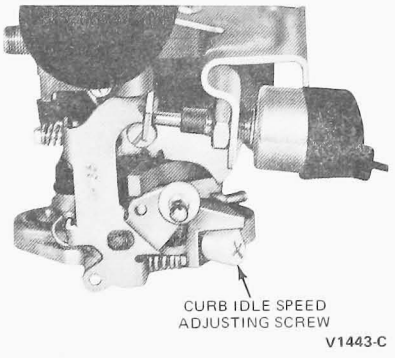

FIG. 5 Curb Idle Speed Adjusting Screw

ENGINE ON

Set the parking brake while making idle mixture and speed adjustments.

1. The engine and underhood temperatures must be stabilized before idle adjustments are made. Run the engine a minimum of 20 minutes at 1500 rpm. This can be done by positioning the fast idle screw on the intermediate step of the fast idle cam.
2. Check the initial ignition timing and the distributor advance and retard as described in Group 23.

Use an accurate reading tachometer when checking the initial ignition timing and idle fuel mixture and speed.

3. On a vehicle with a manual-shift transmission, the idle setting must be made only when the transmission is in **neutral.**

On a vehicle with an automatic transmission, the idle adjustment is made with the parking brake on the transmission selector lever in the Drive range, except as noted when using an exhaust gas analyzer (Part 24-01).

4. Be sure the choke plate is in the full-open position.
5. Turn the headlights on high beam, to place the alternator under a load condition in order to properly adjust to the specified engine idle speed during the adjustment procedure.
6. The Final idle speed adjustment is made with the air conditioner (if so equipped) turned **OFF.**
7. Adjust the engine curb idle rpm to specifications. The tachometer reading (rpm) must be taken with the air cleaner installed. On vehicles with less than 50 miles, set the idle speed approximately 25 rpm bellow specifications to allow for an idle rpm increase as the engine **loosens up** in the first 100 miles of driving.

On the Model YF 1-V equipped with a solenoid throttle positioner (Fig. 6), loosen the jam nut on the solenoid at the bracket and rotate the solenoid in or out to obtain the specified curl idle rpm. Disconnect the solenoid lead wire at the bullet connector near the loom, set automatic transmission in Neutral, then adjust the carburetor throttle stop screw to obtain 500 rpm. Connect the solenoid lead wire and open the throttle slightly by hand. The solenoid plunger will follow the throttle lever and remain in the fully extended position as long as the ignition is on and the solenoid energized.

If it is not possible to adjust the idle speed with the air cleaner installed, remove it and make the adjustment. Then replace the air cleaner and check again for the specified rpm.

8. Turn the idle mixture adjusting screw inward to obtain the smoothest idle possible within the range of the idle limiter.

Check for idle smoothness only with the air cleaner installed.

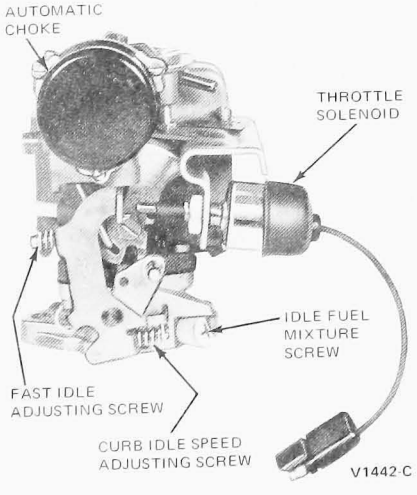

FIG. 4 Carburetor Adjustments—Model YF 1-V

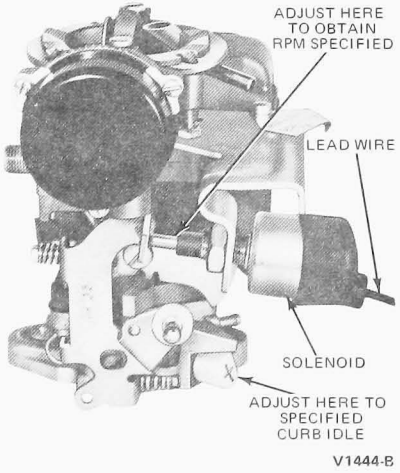

FIG. 6 Carter Model YF 1-V With Throttle Solenoid Positioner

FAST IDLE CALM INDEX SETTING

1. Position the fast idle screw on the kickdown step of the fast idle cam against the shoulder of the high step.
2. Adjust by bending the choke plate connecting rod to obtain the specified clearance between the lower edge of the choke plate and the carburetor bore.

FAST IDLE SPEED

The fast idle adjustment screw contacts one edge of the fast idle cam. The cam permits a faster engine idle speed for smoother running when the engine is cold during choke operation. As the choke plate is moved through its range of travel from the closed to the open position, the fast idle cam pick-up lever rotates the fast idle cam. Various positions on the fast idle cam permit a slower idle rpm as engine temperature rises and choking is reduced. Make certain the curb idle speed and mixture are adjusted to specification before attempting to set the fast idle speed.

MANUAL CHOKE CARBURETOR

1. With the engine operating temperature normalized (hot), air cleaner removed and a tachometer attached, manually rotate the fast idle cam to the top step while holding the choke plate fully open.
2. Turn the fast idle adjusting screw inward or outward as required to obtain the specified fast idle rpm.

AUTOMATIC CHOKE CARBURETOR

1. With the engine operating temperature normalized (hot), air cleaner removed and a tachometer attached, manually rotate the fast idle cam until the fast idle adjusting screw rests on the specified step of the cam.
2. Turn the fast idle adjusting screw (Fig.) inward or outward to obtain the specified rpm.

When setting fast idle speed, all vacuum distributor and EGR controls must be by-passed to insure proper speeds during cold operation. This can be achieved through the use of a jumper hose from the carburetor DIST part to the vacuum advance part on the distributor. The EGR vacuum source should be disconnected and plugged during the adjustment.

ANTI-STALL DASHPOT

The engine idle mixture speed must be properly adjusted before adjusting the anti-stall dashpot.

1. Remove the air cleaner.
2. Loosen the anti-stall dashpot locknut.
3. With the choke plate open, hold the throttle plate closed (idle position), and check the clearance between the throttle lever and dashpot plunger tip with a feeler gauge of the specified clearance dimension. Turn the dashpot inward or outward to obtain the specified clearance and tighten the lock nut. **The clearance must be measured with the plunger fully depressed.**

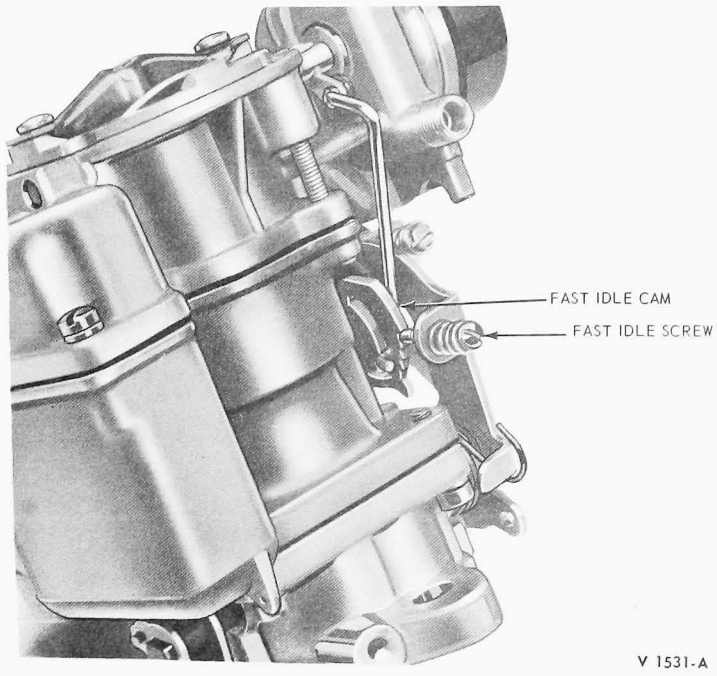

FIG. 7 Fast Idle Speed Adjustment

AUTOMATIC CHOKE THERMOSTATIC SPRING HOUSING ADJUSTMENT

The automatic choke has an adjustment to control its reaction to engine temperature. By loosening the clamp screws that retain the thermostatic spring housing to the choke housing, the spring housing can be turned to alter the adjustment. Refer to the specifications for the proper setting.

1. Remove the air cleaner assembly from the carburetor.
2. Loosen the thermostatic spring housing clamp retaining screws. Set the spring housing to the specified index mark and tighten the clamp retaining screws.
3. If other carburetor adjustments are not required, install the air cleaner assembly on the carburetor.

FLOAT ADJUSTMENT

FUEL LEVEL

The dry fuel level float adjustment for the Carter Model YF 1-V carburetor is a final float or fuel level adjustment.

1. Remove the carburetor air horn and gasket from the carburetor. Refer to Air Horn to Main Body Gasket Replacement for the proper procedure.
2. Fabricate a float level gauge (Fig. 8) to the specified float level dimension.

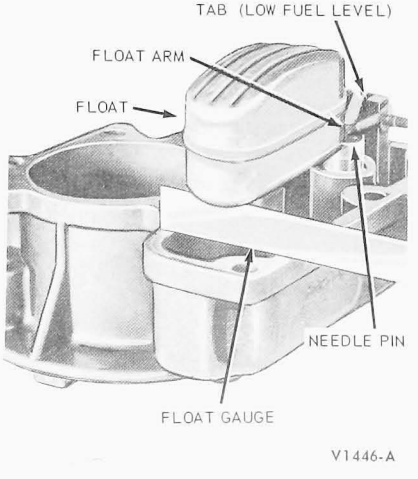

FIG. 8 Fuel Level Float Adjustment

3. Invert the air horn assembly, and check the clearance from the top of the float to the bottom of the air horn with the float level gauge (Fig. 7). Hold the air horn at eye level when gauging the float level. The float arm (lever) should be resting on the needle pin. **Do load the needle when adjusting the float.** Bend the float arm as necessary to adjust the float level (clearance). **Do not bend the tab at the end of the float arm, because it prevents the float from striking the bottom of the fuel bowl when empty.**
4. Install the carburetor air horn and a new gasket on the carburetor. Refer to Carburetor Air Horn to Main Body Gasket Replacement for the proper procedure.

DRY FLOAT DROP

1. Remove the carburetor air horn and gasket as described in this Part.
2. Fabricate a float drop gauge to the specified dimension.
3. Hold the air horn upright and let the float hang free. Measure the maximum clearance from the top of the float to the bottom of the air horn with the float drop gauge. Hold the air horn at eye level when gauging the dimension.
4. To adjust, bend the tab at the end of the float arm to obtain the specified setting.
5. Install the carburetor air horn and a new gasket as described in this Part.

METERING ROD

1. Remove the carburetor air horn and gasket from the carburetor.
2. Back out the idle speed adjusting screw until the throttle plate is closed tight in the throttle bore.

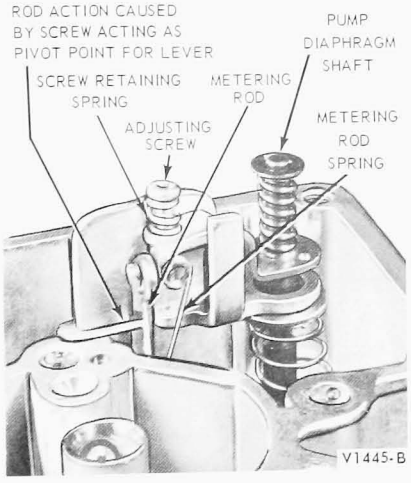

FIG. 9 Metering Rod Adjustment

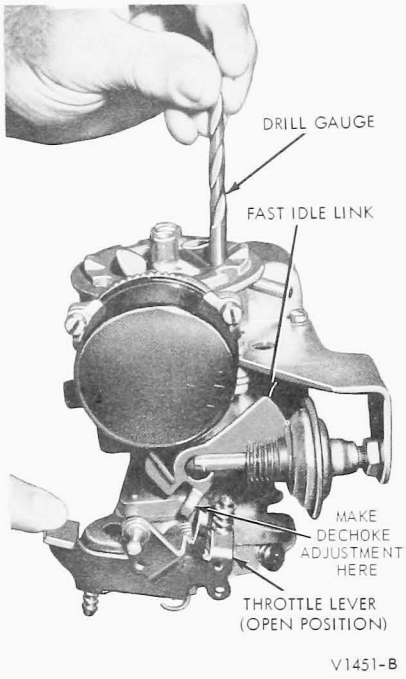

FIG. 10 Dechoke Clearance Adjustment

3. Press down on the end of the pump diaphragm shaft until the assembly bottoms.
4. To adjust the metering rod, hold the diaphragm assembly as in Step 3, then, turn the rod adjustment screw (Fig. 9) until the metering rod just bottoms in the body casting.
5. Turn the metering rod adjustment screw in (clockwise) **one additional turn for the final adjustment.**
6. Install a new gasket and the carburetor air horn.

DECHOKE CLEARANCE

1. Remove the air cleaner.
2. Hold the throttle plate fully open and choke the choke plate as far as possible without forcing it. Use a drill of the proper diameter to check the clearance between the choke plate and air horn (Fig. 10).
3. If the clearance is not within specification, adjust by bending the arm on the choke trip lever of the throttle lever. Bending the arm downward will decrease the clearance, and bending it upward will increase the clearance. Always recheck the clearance after making any adjustment.
4. If the choke plate clearance and fast idle cam linkage adjustment was performed with the carburetor on the engine, adjust the engine idle speed and fuel mixture. Adjust the dashpot (if so equipped).

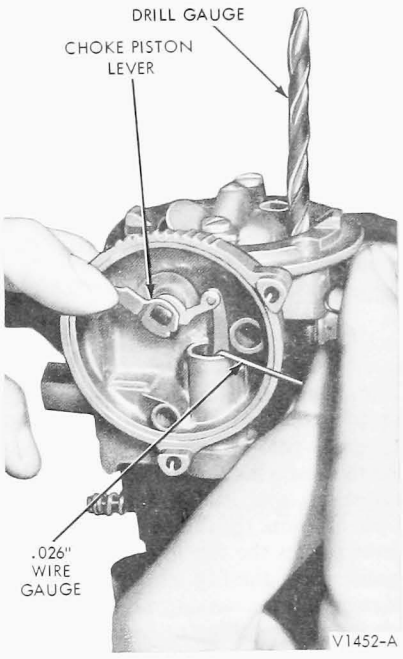

FIG. 11 Pulldown Clearance Adjustment

CHOKE PLATE PULLDOWN

1. Remove the air cleaner. Remove the choke thermostatic spring housing from the carburetor.
2. Bend a 0.026 inch diameter wire gauge at a 90 degree angle approximately 1/8 inch from one end. Insert the bent end of the gauge between the choke piston slot and the right hand slot in the choke housing. Rotate the choke piston lever counterclockwise until the gauge is snug in the piston slot.
3. Exert a light pressure on the choke piston lever to hold the gauge in place, then use a drill gauge with a diameter equal to the specified clearance between the lower edge of the choke plate and the carburetor bore to check clearance (Fig. 11).
4. To adjust the choke plate pulldown clearance, bend the choke piston lever as required to obtain the specified setting. **Be sure the piston link is not distorted when bending the piston lever. A distorted piston link will cause erratic choke operation.**
5. Install the choke thermostatic spring housing and gasket. Set the housing to specifications.

REMOVAL AND INSTALLATION

AIR HORN TO MAIN BODY GASKET

MANUAL CHOKE CARBURETOR

Removal

1. Remove the air cleaner.
2. Disconnect the choke rod at the choke lever and shaft on the carburetor air horn.
3. Disengage the choke cable connecting retainer from the cable clamp and remove the cable from the choke lever. Remove the air horn assembly attaching screws, dashpot and bracket assembly and air horn gasket. Discard the gasket.

Installation

1. Install a new air horn to main body gasket. **Make sure all holes in the new gasket have been properly punched and that no foreign material has adhered to the gasket. Install the air horn assembly, dashpot and bracket assembly and air horn attaching screws. Install the choke cable.**
2. Install the air cleaner. Start the engine and run it until normal operating temperature is reached. Adjust the idle speed and fuel mixture.

AUTOMATIC CHOKE CARBURETOR

Removal

1. Remove the air cleaner.
2. Disconnect the choke heat tube at the carburetor air horn. Disconnect the fuel inlet line at the carburetor. Disconnect the choke clean air tube.

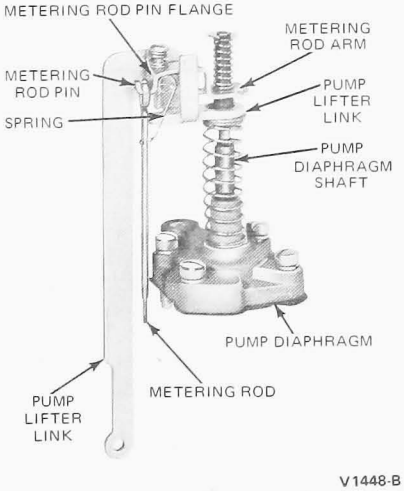

FIG. 12 Accelerator Pump and Lifter Link Assembly

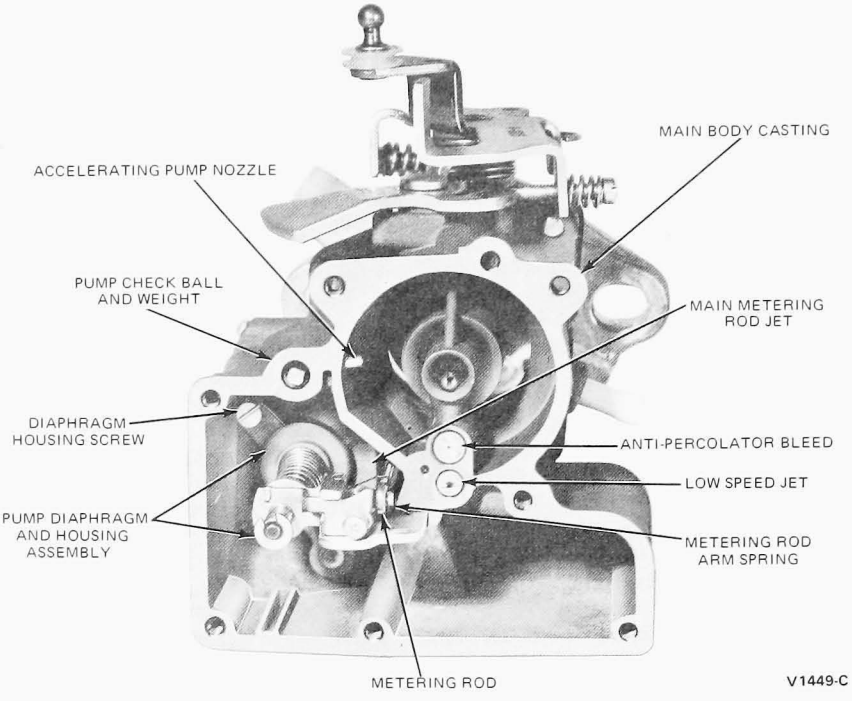

FIG. 13 Pump Diaphragm and Housing

3. Remove the wire clip retaining the link joining the choke shaft lever to the fast idle cam and remove the link. Remove the air horn assembly attaching screws, dashpot and bracket assembly or solenoid throttle positioner and air horn gasket. Discard the gasket.

Installation

1. Install a new air horn to main body gasket. **Make sure all holes in the new gasket have been properly punched and that no foreign material has adhered to the gasket. Install the air horn assembly, dashpot and bracket assembly or solenoid throttle positioner and air horn attaching screws. Position the link joining the fast idle cam to the choke shaft lever and retain in place with the wire clip.**
2. Connect the fuel inlet line and choke heat tube to the carburetor air horn. Connect the choke clean air tube.
3. Install the air cleaner. Start the engine and run it until normal operating temperature is reached. Adjust the idle fuel mixture and idle speed.

MAIN METERING JET, LOW-SPEED JET, METERING ROD, ACCELERATING PUMP OR CHECK BALL

Removal

1. Remove the carburetor from the engine.
2. Remove the carburetor air horn and gasket by following the instructions under Air Horn to Main Body Gasket Replacement.
3. Turn the main body casting upside down and catch the accelerating pump check ball and weight.
4. Loosen the throttle shaft arm screw, and remove the arm and the pump connector link.
5. Remove the accelerating pump diaphragm housing screws. Lift out the pump diaphragm assembly, the pump lifter link the metering rod (Fig. 12).
6. Disengage the metering rod arm spring from the metering rod, and remove the metering rod from the metering rod arm assembly. **Note the location of any washers shimming either spring for proper reassembly. Compress the pump upper spring, and remove the spring retainer. Remove the upper spring, the metering rod arm assembly and the pump lifter link from the pump diaphragm shaft. Compress the**

pump diaphragm shaft. Compress the pump diaphragm spring and retainer, spring and pump diaphragm assembly from the pump diaphragm housing assembly.

7. With the proper size jet tool or screwdriver, remove the low speed jet and the metering rod jet (Fig. 13).

Installation

1. With the proper size jet tool (or screwdriver) install the low speed jet and the metering rod jet (Fig. 13).
2. Install the pump diaphragm in the pump diaphragm housing. Position the pump diaphragm spring on the diaphragm shaft and housing assembly. **Install the spring shim washers in the proper locations.** Install the spring retainer. Install the pump lifter link, metering rod arm and spring assembly, and upper pump spring on the diaphragm shaft. Depress the spring and install the upper pump spring retainer.
3. Install the metering rod on the metering rod arm and place the looped end of the metering rod arm spring on the metering rod as shown in Fig. 12. Align the pump diaphragm with the diaphragm housing; make sure holes are aligned. Install the housing attaching screws to keep the diaphragm and housing aligned. Adjust the metering rod as described in Adjustment Section of this Part.
4. Install the carburetor air horn and gasket as described under Air Horn to Main Body Gasket Replacement.
5. Install the carburetor on the engine.

FLOAT OR NEEDLE VALVE

Removal

1. Remove the carburetor air horn and gasket by following the instructions under Air Horn to Main Body Gasket Replacement in this Section.
2. Hold the air horn assembly bottom side up, and remove the float pin and float and lever assembly. Turn the air horn assembly over and catch the needle pin, spring and needle and seat.
3. Remove the needle seat and gasket.

Installation

1. Replace the float if the needle pin contact surface is grooved. If the float is serviceable, polish the needle pin contact surface with crocus cloth or steel wool. Replace the float pin if it is worn.
2. Install the needle seat and gasket in the air horn. With the air horn inverted, install the needle, pin spring, needle pin, float and lever assembly and float pin.
3. Adjust the float level to specifications. Refer to Float Adjustment in this Part.
4. Install the carburetor air horn and gasket by following instructions under Air Horn to Main Body Gasket Replacement in this Section.

ANTI-STALL DASHPOT

Removal

1. Remove the air cleaner.
2. Remove the retaining nut and the dashpot from the mounting bracket.

Installation

1. Install the new dashpot and retaining nut on the mounting bracket.
2. Adjust the anti-stall dashpot. Refer to Anti-Stall Dashpot Adjustment for the proper procedure.
3. Install the air cleaner.

CARBURETOR ASSEMBLY

Removal

Flooding, stumble on acceleration and other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of complaint, the carburetor should be carefully removed from the engine without removing the fuel from the bowl. The contents of the bowl may then be examined for contamination as the carburetor is disassembled.

1. Remove the air cleaner.
2. Remove the throttle cable or rod from the throttle lever. Disconnect the distributor vacuum line. EGR vacuum line, in-line fuel filter and the choke heat tube at the carburetor.
3. Disconnect the choke clean air tube from the air horn.
4. Remove the carburetor retaining nuts; then remove the carburetor. Remove the carburetor mounting gasket, spacer (if equipped) and lower gasket, from the intake manifold.

Installation

1. Clean the gasket mounting surfaces of the spacer and carburetor. Place the spacer between two new gaskets and position the spacer and gaskets on the intake manifold. Position the carburetor on the spacer and gasket and secure it with the retaining nuts. To prevent leakage, distortion or damage to the carburetor body flange, snug the nuts; then, alternately tighten each nut in a criss-cross pattern to the specified torque.
2. Connect the in-line fuel filter, throttle cable, choke heat tube, distributor vacuum line and EGR vacuum line.
3. Connect the choke clean air line to the air horn.
4. Adjust the engine idle speed, the idle fuel mixture and anti-stall dashpot (if so equipped). Install the air cleaner.

DISASSEMBLY AND ASSEMBLY

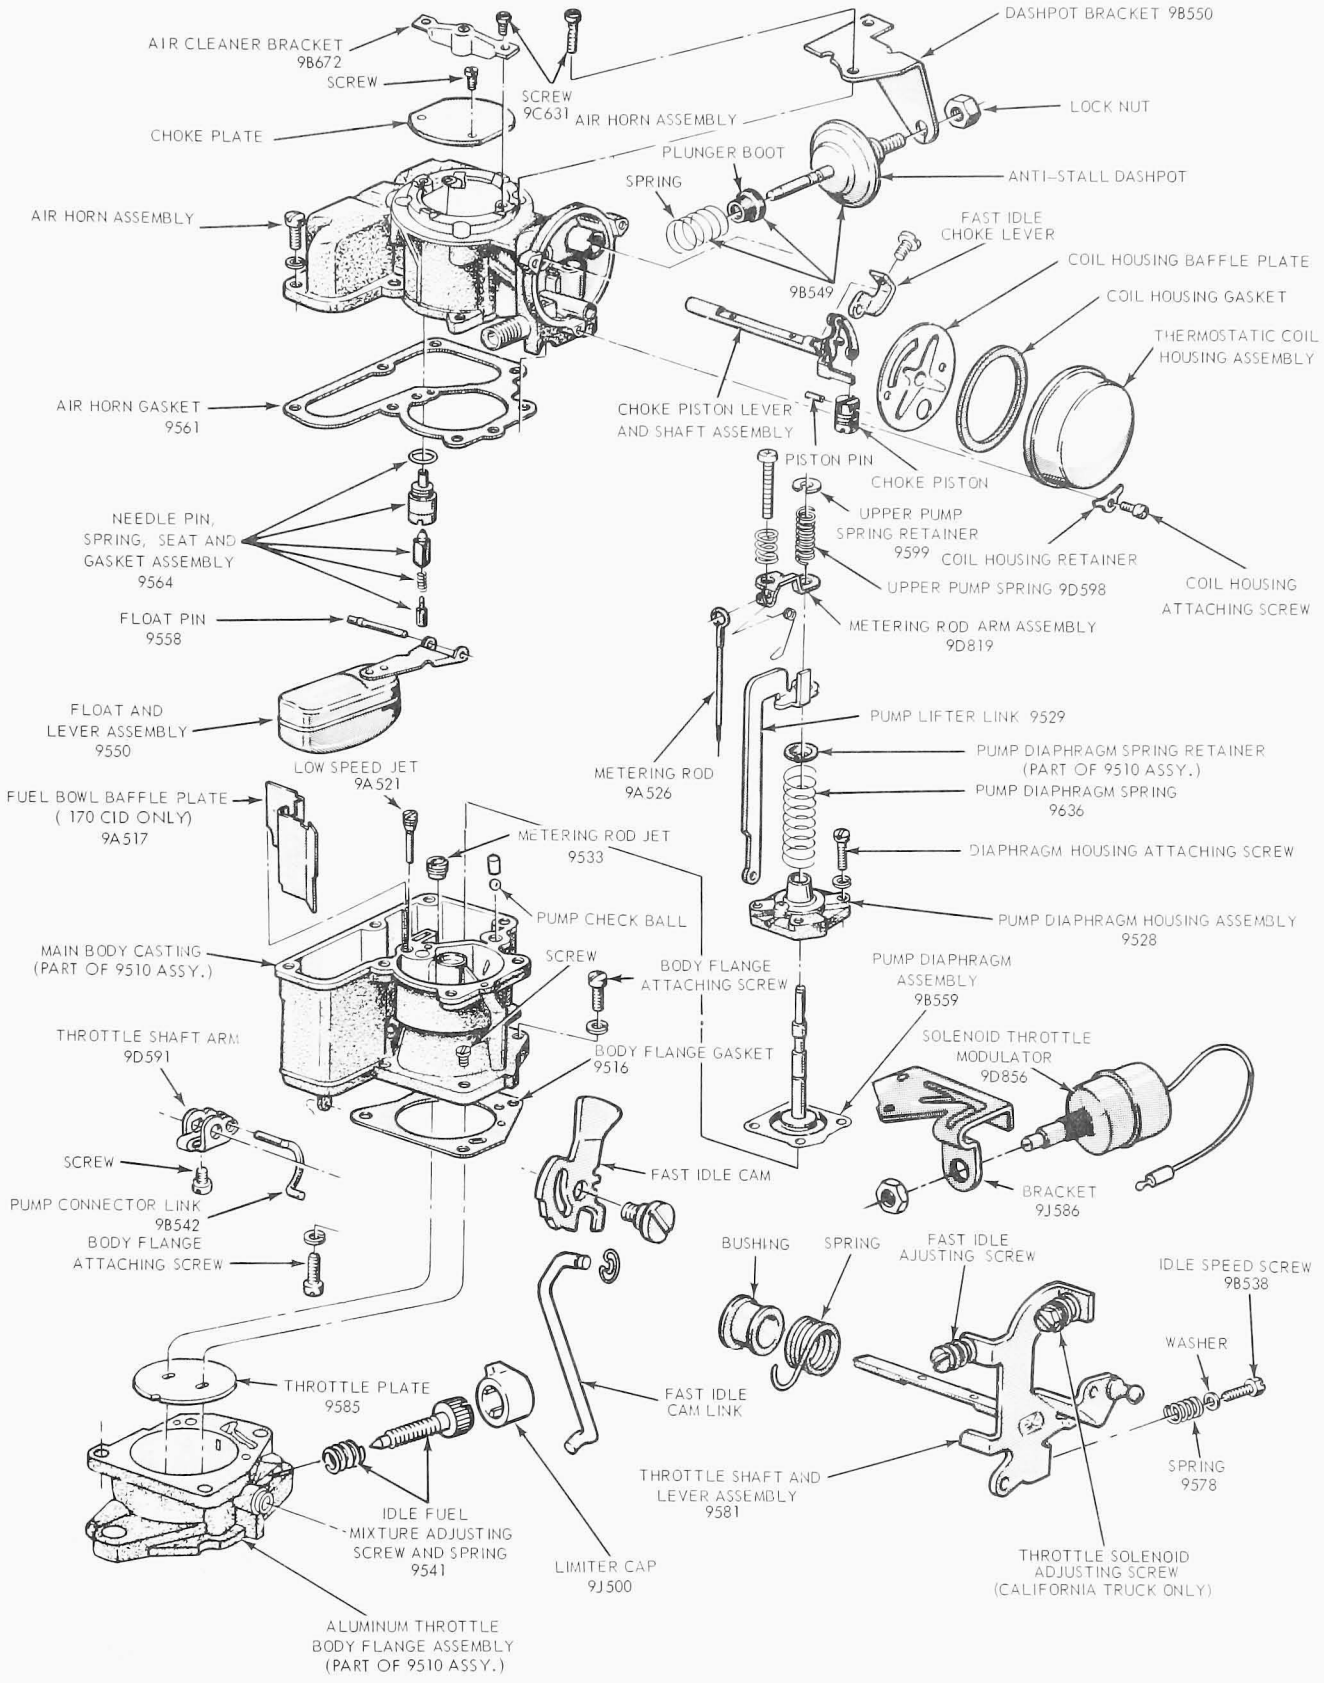
CARBURETOR ASSEMBLY

Use a separate container for the component parts of the various assemblies to facilitate cleaning, inspection and assembly.

The following is a step-by-step sequence of operations for completely overhauling the carburetor; however, certain components of the carburetor may be serviced without a complete disassembly of the unit.

Disassembly

1. Disengage the fast idle connector rod retainer from the choke connector rod, and pull the rod out of the fast idle link (manual choke carburetor).
2. Remove the attaching screws and retainers, the thermostatic spring housing assembly, spring housing gasket, spring housing baffle plate, (automatic choke carburetor) and fast idle link.
3. Remove the air horn assembly attaching screws, dashpot or solenoid and bracket assembly, air horn assembly and air horn gasket (Fig. 14).
4. Hold the air horn assembly bottom side up. Remove the float pin and float and lever assembly. Turn the air horn assembly over and catch the needle pin, spring, and needle.
5. Remove the needle seat and gasket.



V1129-H

FIG. 14 Model YF Carburetor Disassembled

6. Remove the air cleaner bracket. Remove the choke plate attaching screws. File the staked ends, if necessary, and use new screws upon reassembly. Remove the choke plate from the air horn assembly. Remove the choke link lever and attaching screw. Rotate the choke shaft and piston assembly counterclockwise until the choke piston is out of the choke piston cylinder (Fig. 15). Remove the assembly from the air horn. Remove the piston pin and piston, from the choke piston lever and link assembly.
7. Turn the main body casting upside down and catch the accelerating pump check ball and weight.
8. Loosen the throttle shaft arm screw and remove the arm and pump connector link. Remove the fast idle cam and shoulder screw.
9. Remove the accelerator pump diaphragm housing screws. Lift out the pump diaphragm assembly, the pump lifter link, and the metering rod as a unit (Fig. 12).
10. Disengage the metering rod arm spring from the metering rod and remove the metering rod from the metering rod arm assembly. **Note the location of any washers shimming either spring for proper reassembly. Compress the upper pump spring and remove the spring retainer. Remove the upper spring, the metering rod arm assembly and the pump lifter link from the pump diaphragm shaft. Compress the pump diaphragm spring. Remove the pump diaphragm spring retainer, spring and pump diaphragm assembly from the pump diaphragm housing assembly.**
11. **With the proper size jet tool or screwdriver, remove the metering rod jet and the low speed jet (Fig. 13).**
12. Remove the attaching screws and separate the throttle body flange assembly from the main body casting. Remove the body flange gasket.
13. Remove the throttle plate attaching screws. File the staked ends, if necessary, and use new screws upon reassembly. Slide the throttle shaft and lever assembly out of the throttle body flange assembly. **Note the location of the ends of the torsion spring on the throttle shaft for proper reassembly.**

When removing the idle mixture limiter cap, be sure to note the position of the tab. After removing the limiter cap, count the number of turns to lightly seat the needle. This information will be used in reassembly.

Assembly

1. Install the throttle shaft and torsion lever assembly with the throttle return spring and bushing (Fig. 14) in the throttle body flange. Position the throttle plate on the throttle shaft with the notch in the plate aligned with the slotted idle port (Fig. 16) in the throttle body flange. Install the throttle plate attaching screws snug, but not tight. Move the shaft back and forth and rotate it to be sure the throttle plate does not bind in the flange bore. It is necessary that the throttle plate close tightly in the bore, therefore the idle speed screw should be backed out sufficiently to insure that it does not contact the throttle stop. Reposition the plate if necessary. Tighten the screws and stake (or peen) the screws in place.
2. Place a new body flange gasket and the main body casting on the throttle body flange. Install the attaching screws and tighten them evenly.
3. With the proper size jet tool (or screwdriver) install the low speed jet and the metering rod jet (Fig. 13).
4. Install the pump diaphragm in the pump diaphragm housing (Fig. 12). Position the pump diaphragm spring on the diaphragm shaft and housing assembly. Install the spring shim washers in the proper locations. Install the spring retainer. Install the pump lifter link, metering rod arm and spring assembly and upper pump spring on the diaphragm shaft. Depress the spring and install the upper pump spring retainer.
5. Install the metering rod on the metering rod arm and place the looped end of the metering rod arm spring on the metering rod as shown in Fig. 12. Align the pump diaphragm with the diaphragm housing. Make sure the holes are aligned. Install the housing attaching screws to keep the diaphragm and housing aligned.
6. Align the pump housing pump lifter link and metering rod with the main body casting. **Be sure the vacuum passage in the diaphragm housing is aligned with the vacuum passage in the main body.** Install the assembly in the main body casting, being careful to engage the pump lifter link with the main body, and to insert the metering rod in the metering rod jet. Install the pump housing attaching screws snug, but not tight. Push down on the diaphragm shaft to compress the diaphragm and tighten the attaching screws. Adjust the metering rod, following the procedure under Metering Rod Adjustment. Install the fast idle cam and shoulder screw.
7. Install the throttle shaft arm and pump connector link on the throttle shaft and pump lifter link (Fig. 16). Tighten the lock screw.
8. Assemble the choke piston and pin to the choke piston lever and link assembly. Install the choke shaft assembly in the air horn and position the piston as shown in Fig. 15.
9. Align the piston with the cylinder and rotate the shaft assembly clockwise until the piston pin is inside the piston cylinder.

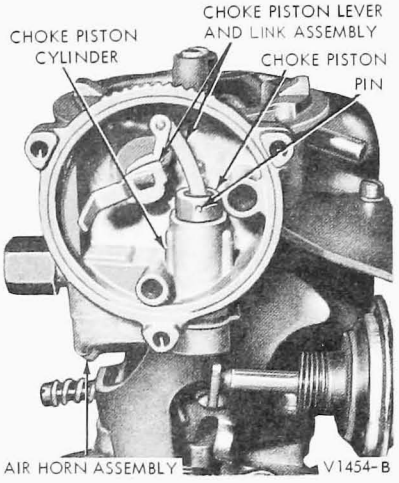


FIG. 15 Removing or Installing Automatic Choke Piston

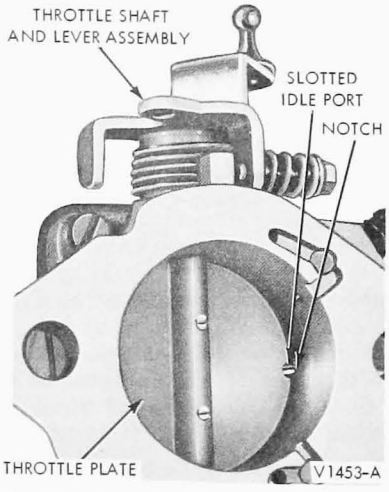

FIG. 16 Throttle Plate and Shaft Arm Installation

10. Position the choke plate on the choke shaft and install the screws snug. Check movement of the choke plate to be sure it does not bind. Tighten the screws and peen or stake them to prevent loosening. Install the choke link lever and tighten the attaching screw.
11. Install the needle seat and gasket in the air horn. With the air horn inverted, install the needle, pin spring, needle pin, float and lever assembly and float pin. Adjust the float level to specifications.
12. Place the pump check ball and weight in the main body casting (Fig. 13). Position a new air horn gasket, the air horn assembly and the anti-stall dashpot and bracket (or solenoid and bracket, if so equipped) on the main body. Install and tighten the attaching screws.
13. Install the thermostatic coil housing, gasket and baffle plate, identification mark facing outward, with the gasket between the baffle and coil housing. Be sure the thermostatic spring engages the choke lever tang. Install the retainers and housing screws. Set the coil housing index to specifications and tighten the screws.
14. Install the air cleaner bracket. Install the fast idle link. Install the choke connector rod on the throttle lever and fast idle link (manual choke carburetor). Engage the connector rod retainer with the choke connector rod when attaching air horn to main body.

STAGED CHOKE VACUUM CONTROL ASSEMBLY	11-09

DESCRIPTION

The Model 2100-D carburetor (Figs. 1 through 4) has two main assemblies the air horn and the main body.

The air horn assembly, which serves as the main body cover, contains the choke plate, choke diaphragm assembly and the internal vents for the fuel bowl.

The main body contains the throttle plates, the accelerating pump assembly, the power valve assembly, and the fuel bowl. The hand throttle control linkage and bracket are attached to the main body; as well as the manual choke linkage and bracket for the 330 MD truck. Some 360 and 390 engines will use a staged choke mechanism. This system releases the choke within 15-60 seconds when underhood temperature is above 60 degrees. Choke release is accomplished through a system of vacuum controlled diaphragms.

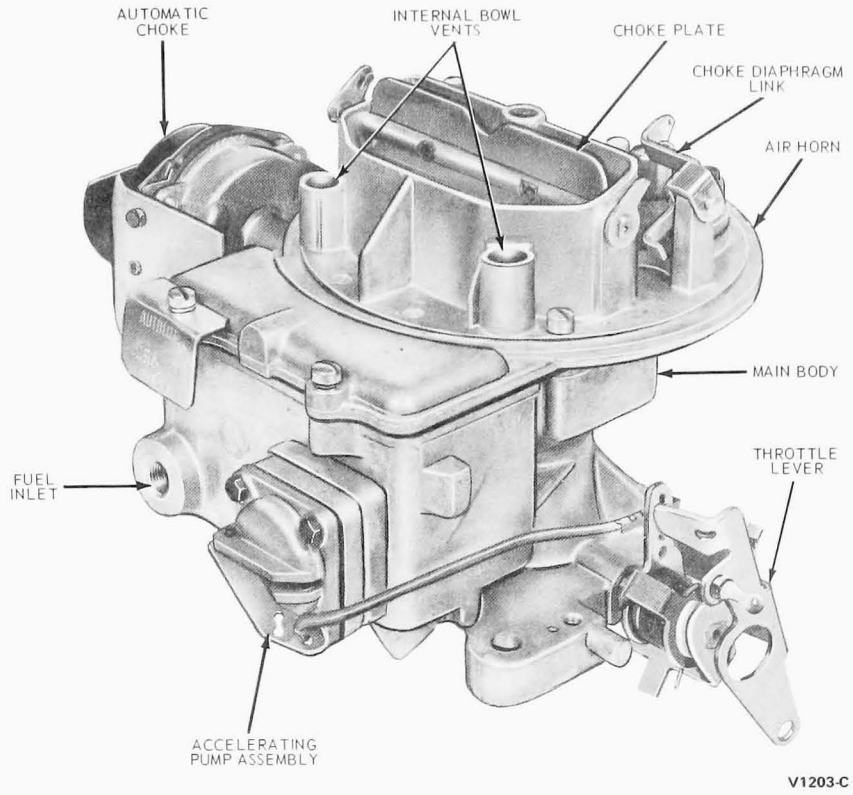

FIG. 1 Model 2100-D 2-V Carburetor—3/4 Left Front View

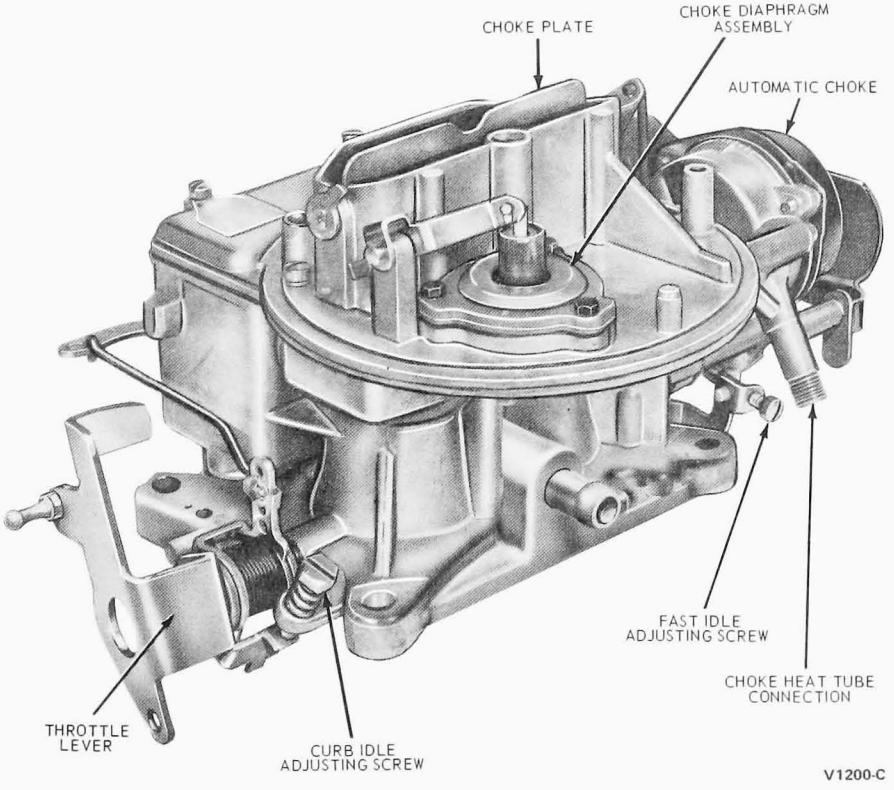

FIG. 2 Model 2100-D 2-V Carburetor—3/4 Left Rear View

On engines not equipped with a staged choke, an electric choke will be used.

The electric choke system consists of a choke cap, thermostatic spring, a bimetal temperature sensing disc (switch), and a ceramic positive temperature coefficient (PTC) heater (Fig. 5). The choke is powered from the center tap of the alternator (Fig. 6). Current is constantly supplied to the ambient temperature switch. The system is grounded through a ground strap connected to the carburetor body. At temperatures below approximately 60 degrees, the switch is open and no current is supplied to the ceramic heater located within the thermostatic spring. Normal thermostatic spring choking action then occurs. At temperatures above approximately 60 degrees, the temperature sensing switch closes and current is supplied to the ceramic heater. As the heater warms, it causes the thermostatic spring to pull the choke plates open within 1-1/2 minutes.

The two bores in the main body contain a main and booster venturi, main fuel discharge, accelerating pump discharge, idle fuel discharge and a throttle plate.

HAND THROTTLE CONTROL LINKAGE

The hand-operated (manual) throttle lever and throttle cable mounting bracket are located adjacent to the choke cam and lever assembly on the main body. The throttle lever is actuated by the throttle cable and a throttle control knob, located on the instrument panel.

As the hand throttle control knob is pulled outward, the throttle cable rotates the manual throttle lever against the fast idle throttle lever, causing the fast idle lever to depress and open the throttle plates. This action gradually increases the engine speed to suit the truck operators requirements.

The throttle control is useful for maintaining constant engine speeds when running power take-off equipment or when performing various service operations. **The vehicle must not be driven with the throttle control knob pulled outward.**

DIAGNOSIS AND TESTING

POWER VALVE TEST

A power valve must not be replaced unless it is leaking sufficiently to cause an unadjustable rough engine idle condition. Fuel accumulation in the power valve cover does not necessarily indicate a damaged power valve. Fuel vapors will be drawn into the vacuum side of the power valve and condense during periods of deceleration. Leakage in the power valve area can be caused by an improperly tightened cover or damaged gaskets. Any gasket sealing deficiencies must be corrected before the power valve is replaced.

If power valve leakage is suspected, the following test procedure must be performed.

1. Remove the carburetor from the intake manifold. Invert the carburetor.
2. Remove the glass bowl from the fixture (Fig. 7). Fill the bowl half-full of water. Install the bowl on the fixture.
3. Connect a line from the vacuum pump to the fitting on top of the fixture. Insert the large OD end of the wand into the tube and attach the other end of the tube to the fitting on the side of the fixture. Slip the rubber gasket (furnished with tool) over the small OD end of the wand. Hold this end against the power valve vacuum pick-up port (Fig. 7).
4. Look for bubble formations in the water in the bowl. A continuous stream of bubbles indicates leakage through the power valve diaphragm or gasket, or the cover or gasket.

If leakage is encountered, the power valve, power valve gasket, cover, and cover gasket should be replaced one at a time with a new part and the test repeated until the source of leakage has been found. If the source of leakage can not be found, the gasket seats are damaged and the appropriate parts should be replaced.

A few bubbles may be noticed immediately upon attaching the vacuum line. The bubbling should stop within approximately 15 seconds or after the air has been removed from the system. If no bubbles are seen, the power valve, gaskets and cover are sealing properly.

ELECTRIC CHOKE TESTS

ELECTRICAL TESTS

Refer to the schematic drawing (Fig. 8).

1. Disconnect the choke lead wire from the choke cap. Connect a jumper wire between the choke cap terminal and the wire terminal. Start the engine.
2. Connect a test light between the connector of the choke lead wire and ground. If the light glows, current is available to the choke cap. The choke cap should be replaced.

If the light does not glow, connect the test light between the alternator stator and the choke lead wire. If the light glows, replace the lead wire.

If the light does not glow, the problem lies in the engine electrical circuit and should be isolated in the usual manner.

FUNCTIONAL TEST

1. Tape a thermometer bulb end to the metallic choke housing. Start the engine
2. If the electrical choke assembly operates at a stabilized temperature of 55 degrees or less, replace the choke cap. To achieve a stabilized temperature of 55 degrees, it may be necessary to use a Motorcraft Choke Tester Kit (LRE 3461).
3. With the engine running and the choke temperature between 80 to 110 degrees, the choke should fully open within 1-1 1/2 minutes. If it does not open within the specified time, check to see if the bi-metallic spring coil is connected to the choke lever tang. If the choke bi-metallic spring is properly connected, replace the choke cap.

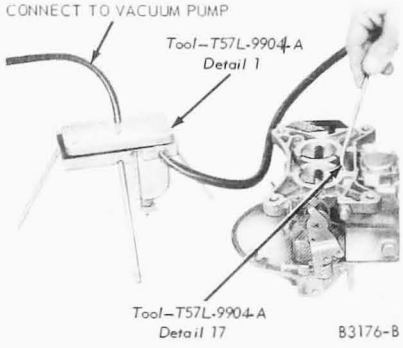

FIG. 7 Typical Power Valve Test

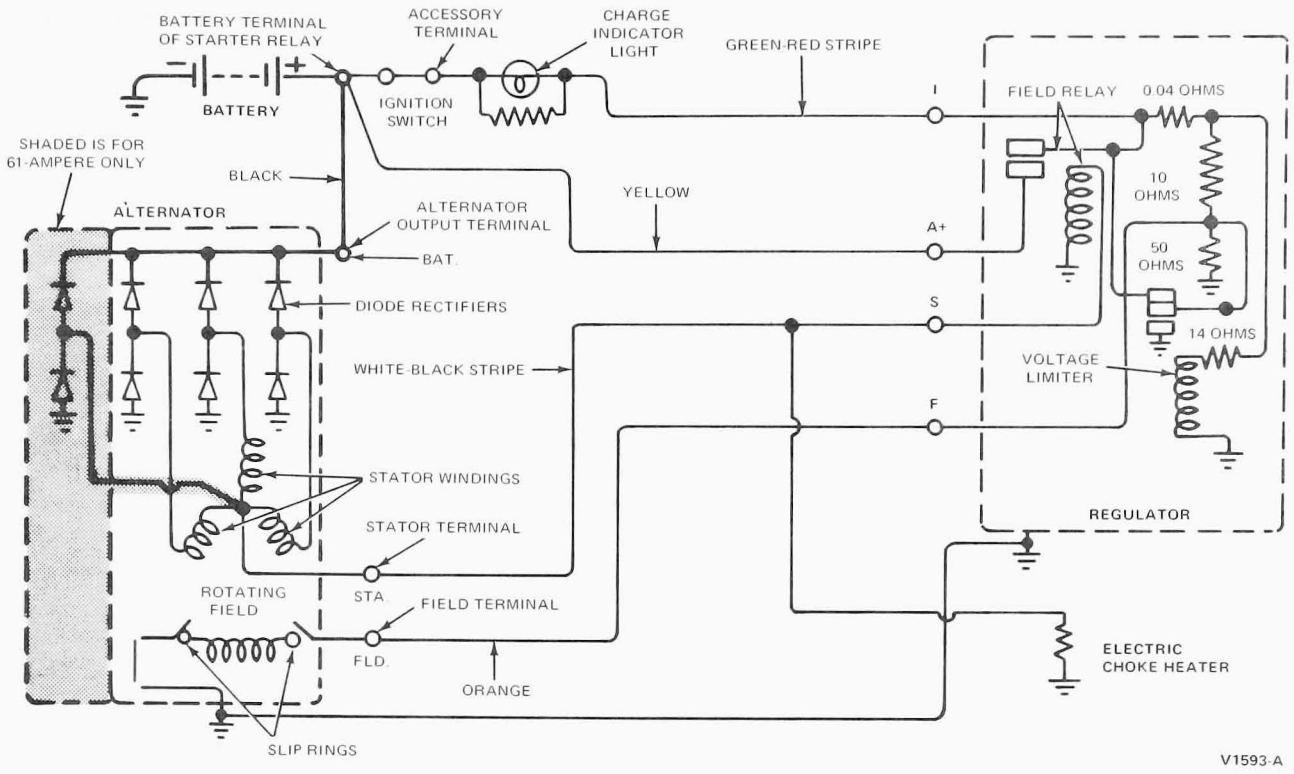

FIG. 8 Wiring Schematic—Electric Choke

ADJUSTMENTS

IDLE SPEED AND FUEL MIXTURE

All carburetors on engines manufactured for use in the U.S. are equipped with idle fuel mixture adjusting limiters. The limiters control the maximum idle richness.

The plastic idle limiter cap is installed on the head of the idle fuel mixture adjusting screws (Fig. 9).

Any adjustment made on carburetors must be within the range of the idle adjusting limiter. **Under no circumstances are the idle adjusting limiters or the limiter stops on the carburetor to be mutilated or deformed to render the limiters inoperative.**

The power valve cover must always be installed with the limiter stops on the cover in position to provide a positive stop for tabs on the idle adjusting limiters (Fig. 9).

A satisfactory idle should be obtainable within the range of the idle adjusting limiters, if all other engine systems are operating within specifications.

Following are the normal procedures necessary to properly adjust the engine idle speed and fuel mixture. The specific operations should be followed in the sequence given whenever the idle speed or idle fuel adjustments are made.

In isolated cases, a satisfactory idle condition may not be achieved by performing the normal procedures. If this occurs, refer to Supplemental Idle Speed and Fuel Mixture Procedures.

NORMAL IDLE FUEL SETTINGS—ENGINE OFF

1. Set the idle fuel mixture screws and limiter caps to the full-counterclockwise position of the limiter caps.

On export vehicles not equipped with exhaust emission control systems, establish an initial idle mixture setting by turning each screw inward until it is lightly seated; then turn it outward 1 1/2 turns. Do not turn the screws tightly against the seat, as this may damage the end of the screw. If the screw end is damaged, it must be replaced before a satisfactory adjustment can be obtained.

2. Back off the curb idle speed adjusting screw (Fig. 10) until the throttle plate(s) seat in the throttle bore(s).

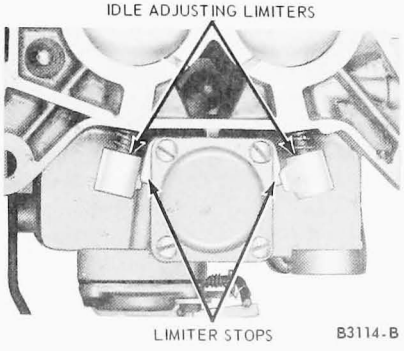

FIG. 9 Idle Fuel Mixture Adjusting Limiters and Limiter Stops—Bottom View

3. Be sure the solenoid throttle positioner is not interfering with the throttle lever (Fig. 10).

It may be necessary to loosen the solenoid to allow the throttle plates to seat in the throttle bores.

4. Turn the idle speed adjusting screw inward until it just makes contact with the screw stop on the throttle shaft and lever assembly. Then, turn the screw inward 1 1/2 turns to establish a preliminary idle speed adjustment (Fig. 10).
5. Set the parking brake while making idle mixture and speed adjustments.

NORMAL IDLE FUEL SETTINGS—ENGINE ON

1. The engine and underhood temperatures must be stabilized before idle adjustments are made. Run the engine a minimum of 20 minutes at 1500 rpm. This can be done by positioning the fast idle screw or cam follower on the kickdown step of the fast idle cam (Fig. 11).
2. Check the initial ignition timing and the distributor advance and retard as described in Part 23-01. Use an accurate reading tachometer and timing light when checking the initial ignition timing and idle fuel mixture and speed.
3. On vehicles with a manual shift transmission, the idle setting must be made only when the transmission is in **neutral.**

On vehicles with an automatic transmission, the idle setting is made with the transmission selector lever in the Drive range, except as noted when using an exhaust gas analyzer.

4. Be sure the choke plate is in the full-open position.
5. **The final idle speed adjustment is made with the air conditioner (if equipped) turned OFF.**
6. Adjust the engine curb idle rpm to specifications. The tachometer reading (rpm) must be taken with the air cleaner installed. On vehicles with less than 50 miles, set the idle speed approximately 25 rpm below specifications to allow for an rpm increase as the engine **loosens up** in the first 100 miles of driving.

If it is not possible to adjust the idle speed with the air cleaner installed; remove it, make the adjustment, then replace the air cleaner and check again for the specified rpm.

Turn the solenoid assembly in or out of the bracket to obtain the specified curb idle rpm, then tighten the lock nut. Disconnect the solenoid lead wire at the connector, set automatic transmission in NEUTRAL, then adjust the carburetor throttle stop screw to obtain 500 rpm. Connect the solenoid lead wire and open the throttle slightly by hand. The solenoid plunger will follow the throttle lever and remain in the fully extended position as long as the ignition is on and the solenoid is energized.

7. Turn the idle mixture adjusting screws inward to obtain the smoothest idle possible within the range of the idle limiters.

Turn the idle mixture adjusting screws inward an equal amount.

Check for idle smoothness only with the air cleaner installed.

FAST IDLE ADJUSTMENT

The fast idle adjusting screw (Fig. 11) contacts one edge of the fast idle cam. The cam permits a faster engine idle speed for smoother running when the engine is cold during choke operation. As the choke plate is moved through its range of travel from the closed to the open position, the fast idle cam pick-up lever rotates the fast idle cam. Each position on the fast idle cam permits a slower idle rpm as engine temperature rises and choking is reduced.

Make certain the curb idle speed and mixture are adjusted to specification before attempting to set the fast idle speed.

1. With the engine operating temperature normalized (hot), air cleaner removed and the tachometer attached, manually rotate the fast idle cam until the fast idle adjusting screw rests on the specified step of the cam.
2. Turn the fast idle adjusting screw inward or outward as required to obtain the specified fast idle rpm.

ANTI-STALL DASHPOT

1. With the engine idle speed and mixture properly adjusted, and the engine at normal operating temperature, loosen the anti-stall dashpot lock nut (Fig. 12).
2. Hold the throttle in the closed position and depress the plunger with a screwdriver blade. Measure the clearance between the throttle lever and the plunger tip. Turn the anti-stall dashpot in a direction to provide the specified clearance between the tip of the plunger and the throttle lever. Tighten the locknut to secure the adjustment.

AUTOMATIC CHOKE THERMOSTATIC SPRING HOUSING ADJUSTMENT

The automatic choke has an adjustment to control its reaction to engine temperature. By loosening the clamp screws that retain the

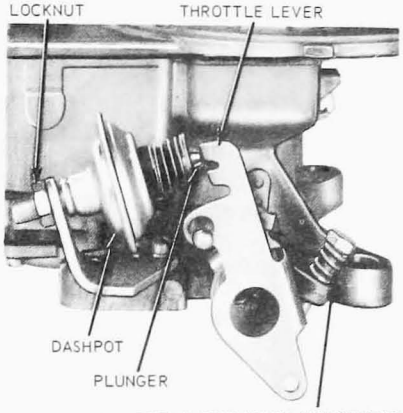

FIG. 10 Curb Idle Speed Adjusting Screw

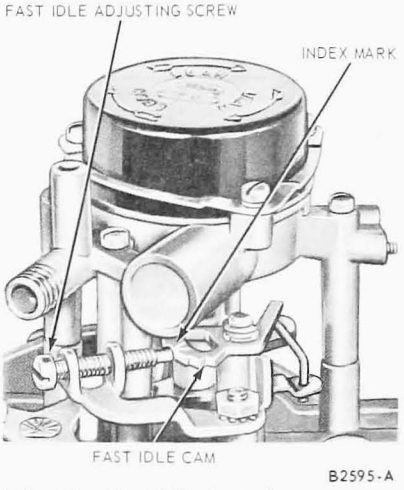

FIG. 11 Fast Idle Speed Adjustment

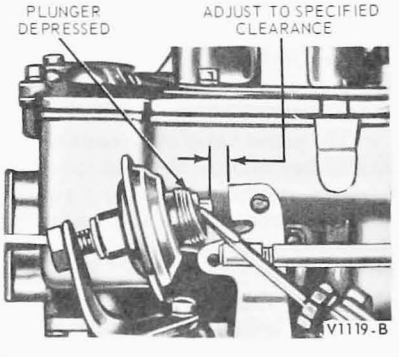

FIG. 12 Typical Anti-Stall Dashpot Adjustment

thermostatic spring housing to the choke housing, the spring housing can be turned to alter the adjustment. Refer to the specifications for the proper setting.

1. Remove the air cleaner assembly, heater hose and mounting bracket (if so equipped) from the carburetor.
2. Loosen the thermostatic spring housing clamp retaining screws. Set the spring housing to the specified index mark (Fig. 13) and tighten the clamp retaining screws.
3. If other carburetor adjustments are not required, install the heater hose and mounting bracket (if so equipped) and the air cleaner assembly on the carburetor.

ACCELERATING PUMP STROKE ADJUSTMENT

The accelerating pump stroke has been set to help keep the exhaust emission level of the engine within the specified limits. The additional holes provided for pump stroke adjustment are for adjusting the stroke for specific engine applications. **The stroke should not be changed from the specified setting.**

If the pump stroke has been changed from the specified setting refer to the following instructions to correct the stroke to specifications.

The primary throttle shaft lever (overtravel lever) has 4 holes and the accelerating pump link has 2 holes (Fig. 14) to control the accelerating pump stroke.

The accelerating pump operating rod should be in the specified hole in the overtravel lever and the inboard hole (hole closest to the pump plunger) in the accelerating pump link (Fig. 14).

1. To release the rod from the retaining clip, press the tab end of the clip toward the rod; then, at the same time, press the rod away from the clip until it is disengaged.
2. Position the clip over the specified hole in the overtravel lever. Press the ends of the clip together and insert the operating rod through the clip and the overtravel lever. Release the clip to engage the rod.

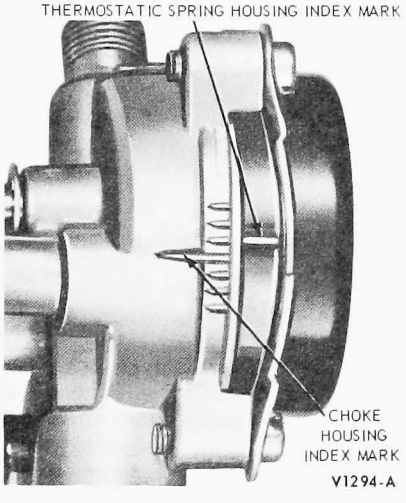

FIG. 13 Automatic Choke Thermostatic Spring Housing Adjustment

CHOKE PLATE PULLDOWN AND FAST IDLE CAM CLEARANCE

CHOKE PLATE PULLDOWN

1. Remove the air cleaner.
2. With the engine at normal operating temperature, loosen the choke thermostatic spring housing retainer screws and set the housing 90 degrees in the **rich** direction.
3. Disconnect and remove the choke heat tube from the choke housing.
4. Turn the fast idle adjusting screw outward **one full turn.**
5. Start the engine, then check for the specified clearance between the lower edge of the choke plate and the air horn wall (Fig. 15).
6. Because the choke plate pulldown is set in production by means of an air-fuel meter, no specific clearance is indicated for pulldown adjustment. If the vehicle shows indication of leaness during cold starting, decrease the clearance between the choke plate and the air horn wall by 0.020 inch. If the engine shows signs of an overrich condition during cold starting, increase the pulldown clearance by 0.020 inch. If additional adjustment is required always make the adjustments in steps of 0.020 inch. If the original pulldown adjustment is lost, set the clearance between the choke plate and the air horn to 0.160 inch. Then adjust as required in steps of 0.020 inch.
7. Connect the choke heat tube and set the choke thermostatic spring housing to specifications. Adjust the fast idle speed to specifications.

FAST IDLE CAM CLEARANCE

1. Rotate the choke thermostatic spring housing 90 degrees in the rich direction.
2. Position the fact idle speed screw on the high step of the cam.
3. Depress the choke pulldown diaphragm against the diaphragm stop screw to place the choke in the pulldown position.
4. While holding the choke pulldown diaphragm depressed, open the throttle slightly and allow the fast idle cam to fall.
5. Close the throttle and check the position of the fast idle cam. The screw should contact the cam at the V mark on the cam.
6. Adjust the fast idle cam adjusing screw to obtain the proper setting.

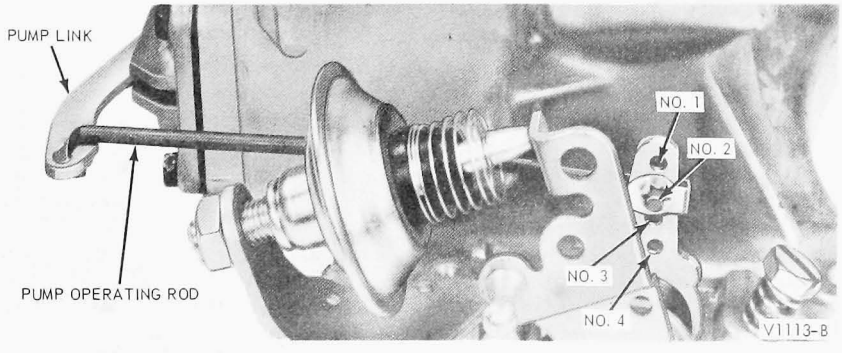

FIG. 14 Accelerating Pump Stroke Adjustment

FUEL LEVEL FLOAT ADJUSTMENT—DRY

The dry float adjustment is a preliminary fuel level adjustment only. The final adjustment (Fuel Level Float Adjustment—Wet) must be made after the carburetor is mounted on the engine.

With the air horn removed, the float raised and the fuel inlet needle seated, check the distance between the top surface of the main body (gasket removed) and the top surface of the float for conformance to specifications. Depress the float tab to seat the fuel inlet needle. Take the measurement near the center of the float at a point 1/8-inch from the free end of the float.

If the cardboard float gauge is used, place the gauge in the corner of the enlarged end section of the fuel bowl (Fig. 16). The gauge should touch the

float near the end, but not on the end radius.

If necessary, bend the tab on the float to bring the setting within the specified limits. This should provide the proper preliminary fuel level setting.

FUEL LEVEL FLOAT ADJUSTMENT—WET

1. Operate the engine to normalize engine temperatures, and place the vehicle on a float surface as near level as possible. Stop the engine.

FUEL LEVEL FLOAT ADJUSTMENT—WET

1. Operate the engine to normalize engine temperatures, and place the vehicle on a flat surface as near level as possible. Stop the engine.
2. Remove the carburetor air cleaner assembly and anchor screw, if they have not been previously removed.
3. Remove the air horn attaching screws and the carburetor identification tag. Temporarily place the air horn and gasket in position on the carburetor main body and start the engine. Let the engine idle for a few minutes, then rotate the air horn out of the way and remove the air horn gasket to provide access to the float assembly.
4. While the engine is idling, use a standard depth scale to measure the vertical distance from the top machined surface of the carburetor main body to the level of the fuel in the fuel bowl (Fig. 17). The measurement must be made at least 1/4-inch away from any vertical surface to assure an accurate reading, because the surface of the fuel is concave (higher at the edges than in the center). Care must be exercised to measure the fuel level at the point of contact with the float with the fuel. Refer to the specifications for the correct fuel level (Wet) setting.
5. **If any adjustment is required, stop the engine to minimize the hazard of fire due to fuel spray when the float setting is disturbed.** To adjust the fuel level, bend the float tab (contacting the fuel inlet valve) upward in relation to the original position to raise the fuel level, and downward to lower it. Each time an adjustment is made to the float tab to alter the fuel level, the engine must be started and permitted to idle for a few minutes to stabilize the fuel level. Check the fuel level after each adjustment until the specified level is obtained.
6. Install a new air horn gasket, the air horn assembly, carburetor identification tag and the attaching screws. Tighten the screws. Install the air cleaner anchor screw and tighten to the specified torque.
7. Check the idle fuel mixture, idle speed adjustments and the carburetor dashpot adjustment (if so equipped). Adjust the carburetor as required.
8. Install the air cleaner.

STAGED CHOKE VACUUM CONTROL ASSEMBLY

This adjustment should be made only if the control unit has been replaced, the carburetor has been overhauled or a choke adjustment has been made. Also, the choke pulldown and fast idle cam adjustments must be made before this adjustment is performed.

1. Be sure the choke plate is fully closed.
2. Measure the clearance between the forward edge of the choke link and the edge of the slot in the choke

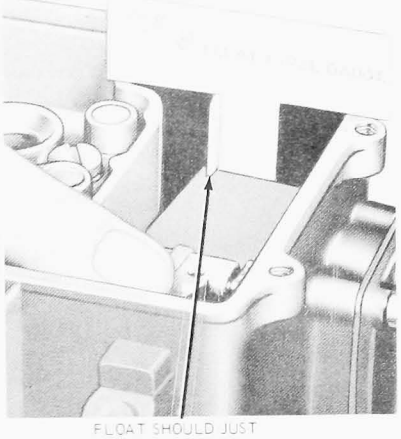

FIG. 16 Fuel Level Float Adjustment—Dry

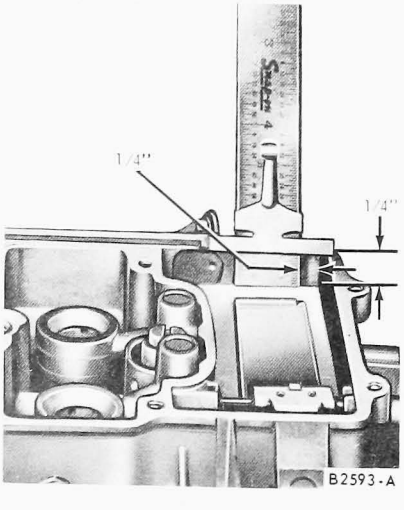

FIG. 17 Fuel Level Float Adjustment (Wet)

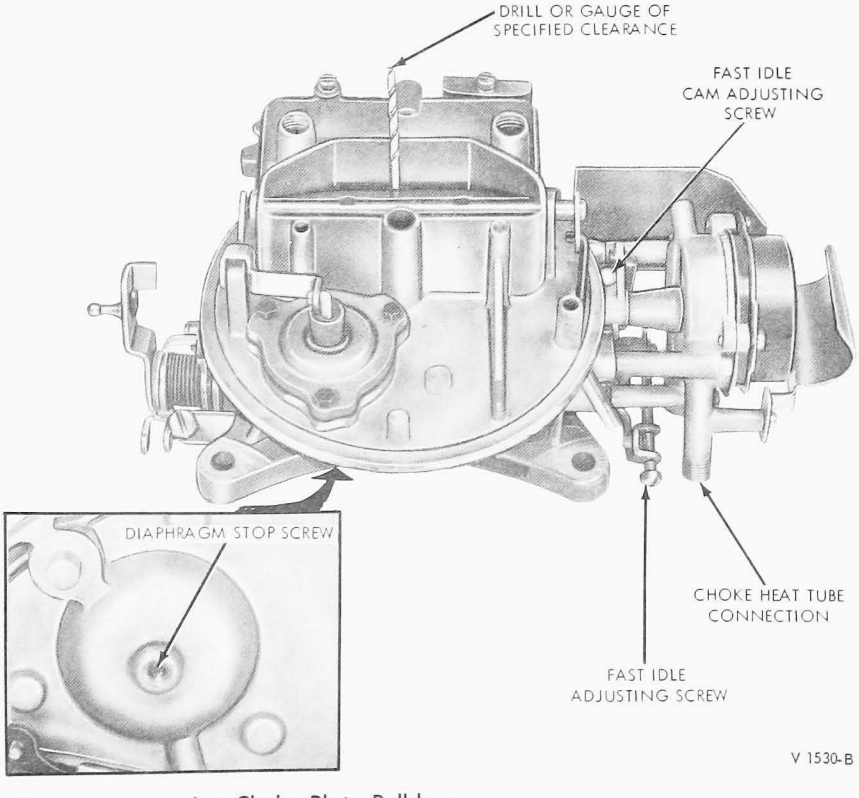

FIG. 15 Measuring Choke Plate Pulldown

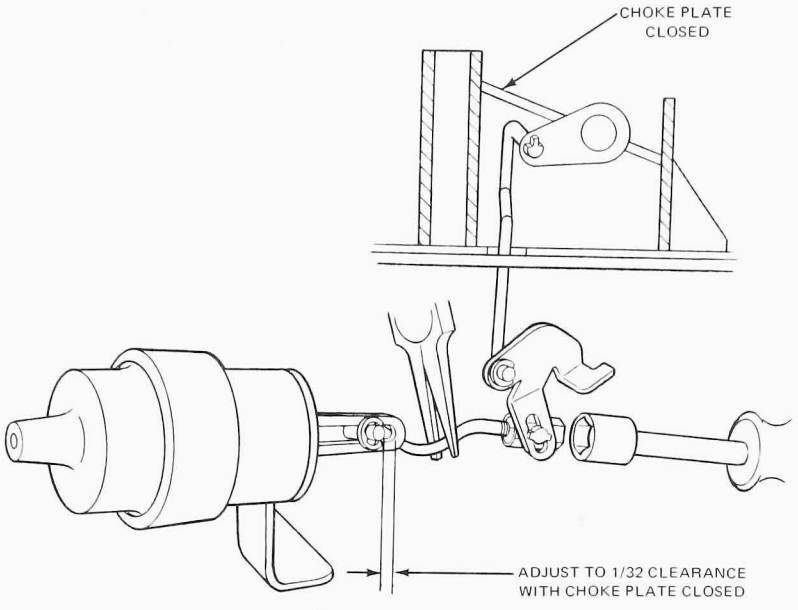

FIG. 18 Staged Choke Vacuum Control Adjustment

vacuum lever, as shown in Fig. 18. Be sure the C-clip is positioned so that the gap is visible.

3. If the adjustment is required, insert a 1/4 inch socket and driver on the nylon adjuster as shown in Fig. 18. Grasp the choke link with needle-nose pliers to prevent flexing and turn the adjuster in or out until the proper clearance is obtained.

REMOVAL AND INSTALLATION

CARBURETOR ASSEMBLY

Removal

Flooding, stumble on acceleration and other performance complaints are in many instances, caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of complaint, the carburetor should be carefully removed from the engine without removing the fuel from the bowl. The contents of the bowl may then be examined for contamination as the carburetor is disassembled.

1. Remove the air cleaner.
2. Remove the throttle cable or rod from the throttle lever. Disconnect the distributor vacuum line, in-line fuel filter and the choke heat tube at the carburetor.
3. Remove the carburetor retaining nuts; then remove the carburetor. Remove the carburetor mounting gasket, spacer (if equipped) and lower gasket from the intake manifold.

Installation

1. Clean the gasket mounting surfaces of the spacer and carburetor. Place the spacer between two new gaskets and position the spacer and gaskets on the intake manifold. Position the carburetor on the spacer and gasket and secure it with the retaining lockwashers and nuts. To prevent leakage, distortion or damage to the carburetor body flange, snug the nuts; then, alternately tighten each nut in a criss-cross pattern to the specified torque.
2. Connect the in-line fuel filter throttle cable, choke heat tube and distributor vacuum line.
3. Adjust the engine idle speed, the idle fuel mixture and the accelerating pump stroke (if required). Install the air cleaner.

AIR HORN TO MAIN BODY GASKET

Removal

1. Remove the air cleaner. Remove the air cleaner anchor screw.
2. Disconnect the automatic choke clean air tube at the carburetor.
3. Remove the automatic choke plate operating rod to choke lever retainer.
4. Remove the air horn attaching screws and lock washers, and the carburetor identification tag. Remove the air horn gasket.

Installation

1. Install a new air horn to main body gasket. **Make sure all holes in the new gasket have been properly punched and that no foreign material has adhered to the gasket.**
2. Position the air horn on the main body and gasket so that the choke plate operating rod fits into the opening in the choke housing lever. Install the choke plate rod retainer.
3. Install the air horn attaching screws and lock washers and the identification tag. Install the air cleaner anchor screw, and tighten to the specified torque.
4. Connect the automatic choke clean air tube to the carburetor.
5. Adjust the idle fuel mixture and idle speed and the dashpot as outlined in this Section.
6. Install the carburetor air cleaner assembly.

FLOAT, NEEDLE VALVE AND SEAT, INLET SCREEN OR MAIN JETS

Removal

1. Remove the carburetor air horn to main body gasket by following the procedure under Air Horn to Main Body Gasket Replacement.
2. With the use of a screwdriver, pry the float shaft retainer from the fuel

inlet seat. Remove the float, float shaft retainer and fuel inlet needle assembly.

3. If required, remove the fuel inlet needle seat, filter screen and the main jets with a jet wrench. **Be sure the correct (specified) jets are installed.**

Installation

1. If required, install the fuel inlet filter in the inlet valve seat bore. Install the valve seat and gasket. Install the fuel inlet needle valve.
2. Slide the float shaft into the float lever. Position the float shaft retainer on the float shaft.
3. Insert the float assembly into the fuel bowl and hook the float lever tab under the fuel inlet needle clip. Insert the float shaft into the guides at the sides of the fuel bowl.
4. With the use of a screwdriver, position the float shaft retainer on the groove of the fuel inlet needle seat.
5. Refer to Float Adjustment—Dry, and perform a dry float fuel level adjustment on the float.
6. Install the carburetor air horn and gasket and related parts. Refer to Air Horn to Main Body Gasket Replacement.
7. Refer to Fuel Level Float Adjustment—Wet, and perform the wet fuel level adjustment procedures.
8. Adjust the idle fuel mixture and engine idle speed.

ACCELERATING PUMP DIAPHRAGM AND/OR ELASTOMER VALVE

Removal

1. Remove the carburetor air horn to main body gasket following the procedure under Air Horn to Main Body Gasket Replacement.
2. Remove the accelerating pump operating rod retainer. To release the rod from the retainer, press the tab ends of the clip together; then, at the same time, press the rod away from the clip until it is disengaged. Remove the rod. Remove the accelerating pump cover, diaphragm assembly and spring.
3. If inspection proves it necessary to remove the Elastomer valve, grasp it firmly and pull it out. **If the Elastomer valve tip broke off during removal, be sure to remove the tip from the fuel bowl. An Elastomer valve must be replaced whenever it is removed from the main body.**

Installation

1. If the Elastomer valve was removed, lubricate the tip of a new valve and insert the tip into the accelerator pump cavity. Using needle nosed pliers, reach into the fuel bowl and grasp the valve tip. Pull the valve in until it seats, and cut off the tip forward of the retainer shoulder. Remove the tip from the bowl.
2. Position the new accelerating pump diaphragm assembly to the cover and place the cover and diaphragm assembly in position on the return spring and main body. **The large end of the spring must face the Elastomer valve.** Install the cover screws finger-tight. Push the accelerating pump plunger the full length of travel and tighten the cover screws.
3. Position the accelerating pump operating rod in the inboard hole (hole closest to the pump plunger).
4. Adjust the accelerating pump stroke to specification.
5. Install the carburetor air horn and gasket. Refer to the Air Horn to Main Body Gasket Replacement.

CHOKE DIAPHRAGM ASSEMBLY

Removal

1. Remove the air cleaner.
2. Remove the diaphragm cover attaching screws, then lift the cover, diaphragm assembly and spring from the air horn (Fig. 19).**It will not be necessary to remove the diaphragm stop screw on the underside of the air horn.**
3. Remove the diaphragm rod from the end of the lever.

Installation

1. Position the diaphragm spring in the air horn. Place the cover on top of the diaphragm, then attach the diaphragm rod to the end of the lever.
2. Install the cover attaching screws and tighten to the specified torque.
3. Set the choke plate pulldown and fast idle cam clearance.
4. Tighten the air cleaner anchor screw to the specified torque to help provide a vacuum seal between the air horn and main body. **The choke diaphragm vacuum passage is in the rear portion of the carburetor.**
5. Install the air cleaner.

IDLE LIMITER CAPS

Removal

1. Remove the carburetor.
2. Remove the plastic limiter caps by cutting with side-cutter pliers and knife. After the cut is made, carefully pry the limiter apart, then remove them from the idle fuel adjustment screws.

Installation

1. Install the carburetor.
2. Set the carburetor to the correct idle air-fuel ratio, using the exhaust gas analyzer.
3. When the idle air-fuel ratio is within specifications, install a colored plastic service limiter cap.

When installing the limiter cap use care not to turn the idle mixture screws with the caps. Position the caps so that they are in the maximum counterclockwise position with the tab of the limiter against the stop of the carburetor.

The idle mixture adjusting screws will then be at the maximum allowable outward, or rich, setting.

To install the service limiter cap, use a straight, forward pushing force with a 3/8-inch drift or socket wrench extension.

4. Recheck the air-fuel ratio with the air cleaner installed, using the exhaust gas analyzer to make sure the limiter caps are properly installed.

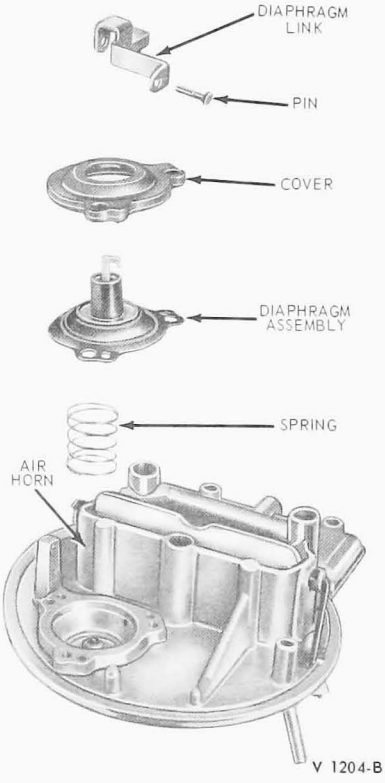

FIG. 19 Choke Diaphragm Assembly

MAJOR REPAIR OPERATIONS

DISASSEMBLY

To facilitate working on the carburetor, and to prevent damage to the throttle plates, install carburetor legs on the base. If legs are unavailable, install 4 bolts (about 2 1/4 inches long of the correct diameter) and 8 nuts on the carburetor base.

Use a separate container for the component parts of the various assemblies to facilitate cleaning, inspection and assembly.

Refer to Part 24-01 for Cleaning and Inspection.

The following is a step-by-step sequence of operations for completely overhauling the carburetor. However certain components of the carburetor may be serviced without a complete disassembly of the entire unit. For a complete carburetor overhaul, follow all of the steps. To partially overhaul a carburetor or to install a new gasket kit, follow only the applicable steps.

AIR HORN

1. Remove the air cleaner anchor screw.
2. Remove the automatic choke control rod retainer.
3. Remove the air horn attaching screws, lock washers and the carburetor identification tag. Remove the air horn and air horn gasket.
4. Remove the choke control rod by loosening the screw that secures the choke shaft lever to the choke shaft. Remove the rod from the air horn. Slide the plastic dust seal out of the air horn.
5. Remove the choke diaphragm assembly (Fig. 19).
6. If it is necessary to remove the choke plate, remove the staking marks on the choke plate attaching screws and remove the screws. Remove the choke plate by sliding it out of the shaft from the top of the air horn. Slide the choke shaft out of the air horn.

If the tips of the choke plate screws are flared excessively, file off the flared portion to prevent damage to the threads in the shaft.

AUTOMATIC CHOKE

1. Remove the fast idle cam retainer (Fig. 20).
2. Remove the thermostatic choke spring housing attaching screws and remove the clamp, housing and gasket.
3. Remove the choke housing assembly attaching screws. If the air horn was not previously removed, remove the choke control rod retainer. Remove the choke housing assembly, gasket and the fast idle cam and rod from the fast idle cam lever.
4. Remove the choke lever attaching screw and washer. Remove the choke lever and fast idle cam lever from the choke housing.

MAIN BODY

1. With the use of a screwdriver, pry the float shaft retainer from the fuel inlet seat (Figs. 21 and 22). Remove the float, float shaft retainer and fuel inlet needle assembly. Remove the retainer and float shaft from the float lever.

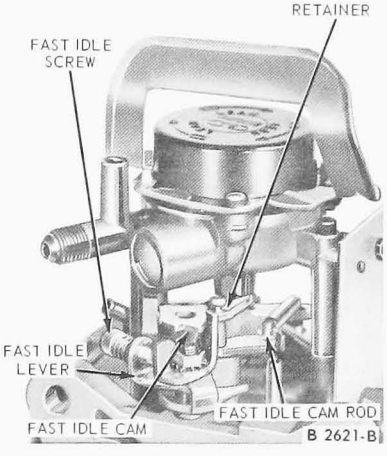

FIG. 20 Fast Idle Cam and Fast Idle Lever

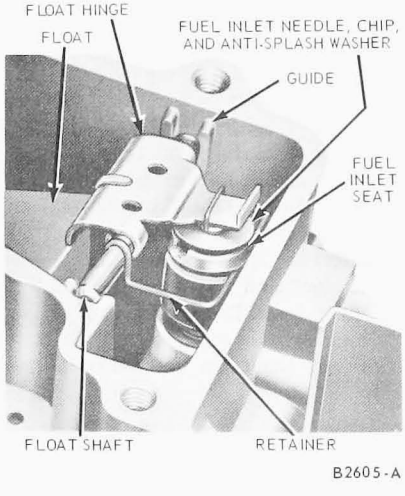

FIG. 21 Float Assembly

2. Remove the fuel inlet needle, seat, filter screen, and the main jets with a jet wrench.
3. Remove the booster venturi screw (accelerator pump discharge), air distribution plate, booster venturi and gasket. Invert the main body and let the accelerating pump discharge weight and ball fall into the hand.

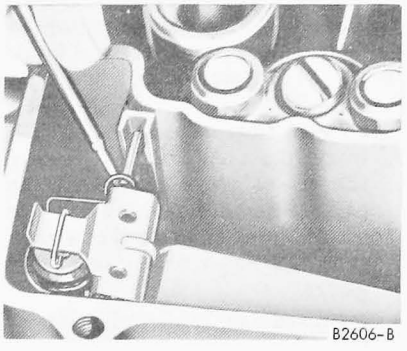

FIG. 22 Removing or Installing Float Shaft Retainer

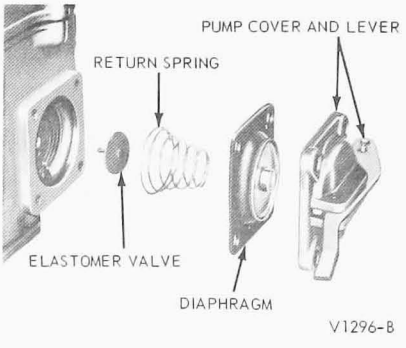

FIG. 23 Accelerating Pump Assembly

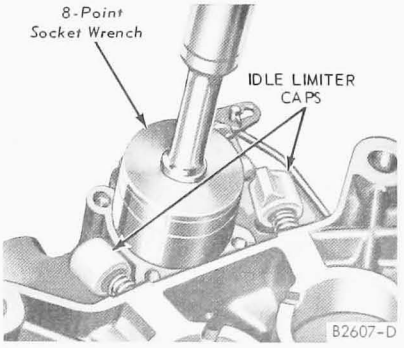

FIG. 24 Removing or Installing Power Valve Discard the gasket.

4. Remove the accelerator pump operating rod from the over-travel lever and the retainer. **To release the operating rod from the over-travel lever retainer, press the ends of the retainer together; then, at the same time, press the rod away from the retainer until it is disengaged.** Remove the rod and retainer.
5. Remove the accelerating pump cover attaching screws. Remove the accelerating pump cover, diaphragm assembly and spring (Fig. 23).
6. If it is necessary to remove the Elastomer valve, grasp it firmly and pull it out. If the Elastomer valve tip broke off during removal, be sure to remove the tip from the fuel bowl. **An Elastomer valve must be replaced whenever it has been removed from the carburetor.**
7. Invert the main body and remove the power valve cover and the gasket. Remove the power valve with a box wrench or socket wrench (Fig. 24). Remove the power valve gasket.
8. Remove the idle fuel mixture adjusting screws (needles) and the springs. Remove the limiters from the adjusting screws.
9. If necessary, remove the nut and washer securing the fast idle adjusting lever assembly to the throttle shaft, and remove the lever assembly if necessary, remove the idle screw and the retainer from the fast idle adjusting lever.
10. Remove the anti-stall dashpot or solenoid (if so equipped).
11. If it is necessary to remove the throttle plates, lightly scribe the throttle plates along the throttle shaft, and mark each plate and its corresponding bore with a number or letter for proper installation (Fig. 25).
12. Slide the throttle shaft out of the main body.

Clean and inspect the carburetor component parts. Refer to Part 24-01 for the proper procedure.

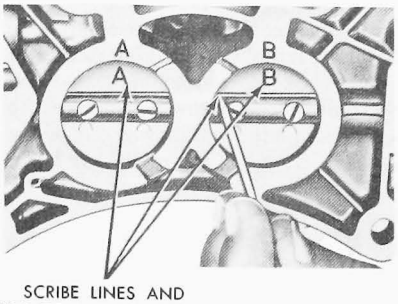
ASSEMBLY

Make sure all holes in the new gaskets have been properly punched and that no foreign material has adhered to the gaskets. Make sure the accelerating pump diaphragm is not torn or cut.

The Model 2100-D 2-V carburetor assembly is shown in Fig. 26.

MAIN BODY

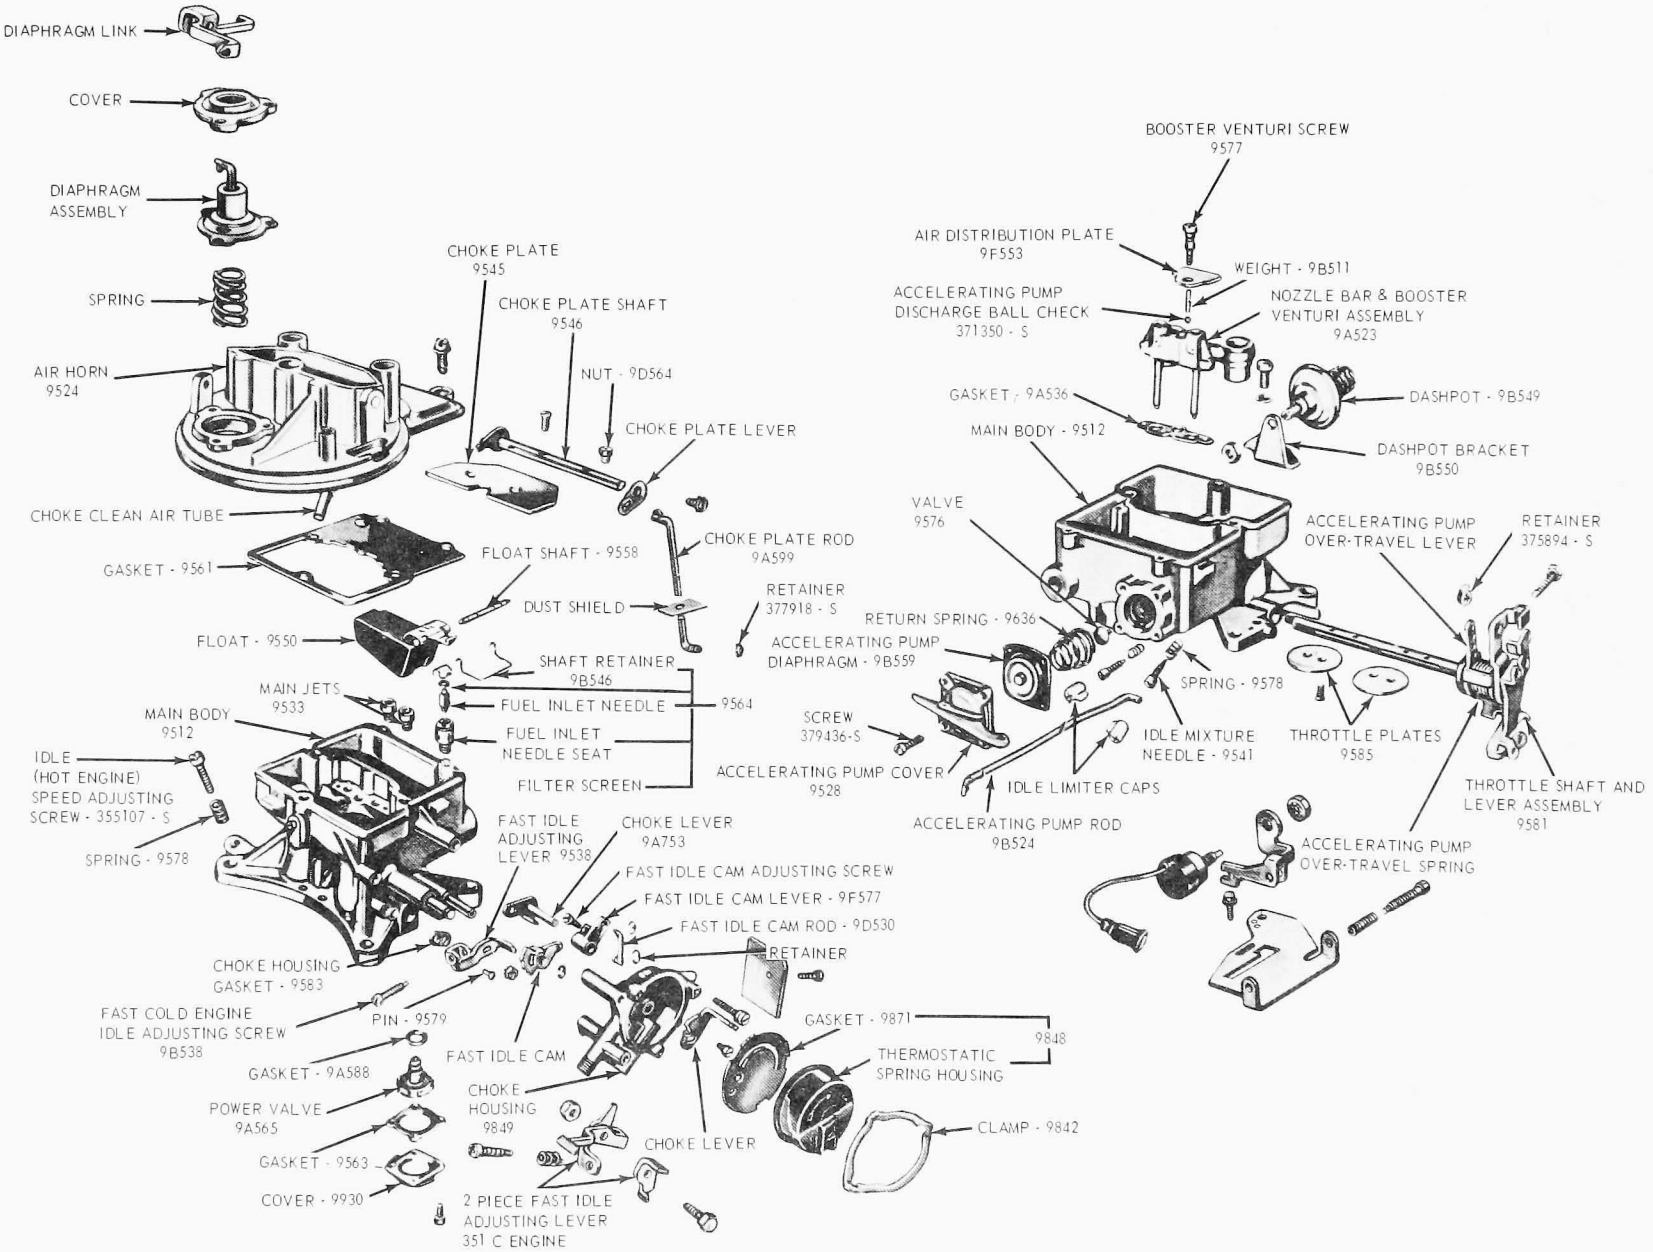
1. Slide the throttle shaft assembly into the main body.
2. Refer to the lines scribed on the throttle plates and install the throttle plates in their proper location with the screws snug, but not tight.
3. Close the throttle plates. Invert the main body, and hold it up to the light. Little or no light should show between the throttle plates and the throttle bores. Tap the plates lightly with a screwdriver handle to seat them. Hold the throttle plates closed and tighten and stake the attaching screws. **When staking the screws, support the shaft and plate on a block of wood or a metal bar to prevent bending of the shaft.**
4. If necessary, install the fast idle screw pin and the screw on the fast idle adjusting lever.
5. Install the anti-stall dashpot, if so equipped.
6. If the fast idle lever was removed, place the fast idle adjusting lever assembly on the throttle shaft and install the retaining washer and nut (Fig. 26).
7. If the Elastomer Valve was removed, lubricate the tip of a new Elastomer valve and insert the tip into the accelerator pump cavity center hole. Using a pair of needle nosed pliers, reach into the fuel bowl and grasp the valve tip. Pull the valve in until it seats in the pump cavity wall and cut off the tip forward the retaining shoulder. Remove the tip from the bowl.
8. Install the accelerating pump diaphragm return spring on the boss in the chamber (Fig. 23). Insert the diaphragm assembly in the cover and place the cover and diaphragm assembly into position on the main body. Install the cover screws.
9. Insert the accelerating pump operating rod into the inboard hole of the accelerating pump actuating lever. Position the accelerating pump operating rod retainer over the specified hole in the over-travel lever. Press the end of the retainer together; then, at the same time, insert the operating rod through the retainer and the hole in the over-travel lever. Release the ends of the retainer to secure the rod.
10. Invert the main body. Install the power valve (enrichment valve) and new gasket with a wrench (Fig. 24). **Tighten the valve securely.**
11. Install the idle mixture adjusting screws (needles) and springs (Fig. 26). Turn the needles in gently with the fingers until they just touch the seat, then back them off 1 1/2 turns for a preliminary idle fuel mixture adjustment. **Do not install the idle mixture limiters at this time.** Install the power valve cover and new gasket. **The power valve cover must be installed with the limiter stops on the cover in position to provide a positive stop for the tabs on the idle adjusting limiters.**
12. Install the main jets and the fuel inlet seat, filter screen, and new gasket. **Be sure the correct jets are installed.**
13. Install the fuel inlet needle assembly in the fuel inlet seat. Fuel inlet needles and seats are matched assemblies. **Be sure the correct needle and seat are assembled together.**
14. Slide the float shaft into the float lever (Fig. 21). Position the float shaft retainer on the float shaft.
15. Insert the float assembly into the fuel bowl and hook the float lever tab under the fuel inlet needle assembly. Insert the float shaft into its guides at the sides of the fuel bowl.
16. With the use of a screwdriver, position the float shaft retainer in the groove on the fuel inlet needle seat (Fig. 22). Check the float setting.
17. Drop the accelerating pump discharge ball into the passage in the main body. Seat the ball with a brass drift and a light hammer. **Make sure**



SCRIBE LINES AND IDENTIFICATION MARKS

B1363-C

FIG. 25 Throttle Plates



V 1137- D

FIG. 26 Model 2100-D 2-V Carburetor

the ball is free in the bore. Drop the accelerating pump discharge weight on top of the ball. Position the new booster venturi gasket and the booster venturi in the main body. Install the air distribution plate and the accelerator pump discharge screw. Tighten the screw.

AUTOMATIC CHOKE

1. Position the fast idle cam lever on the thermostatic choke shaft and lever assembly. **The bottom of the fast idle cam lever adjusting screw must rest against the tang on the choke lever.** Position the teflon bushing around the choke lever shaft. Insert the choke lever into the rear of the choke housing. Position the choke lever so that the hole in the lever is to the left side of the choke housing. Connect the thermostatic choke lever to the choke shaft.
2. Install the fast idle cam rod into the fast idle cam lever. Place the fast idle cam on the fast idle cam rod and install the retainer. Place the choke housing vacuum pick-up port to main body gasket on the choke housing flange. Position the choke housing on the main body and at the same time, install the fast idle cam on the hub on the main body. Position the gasket, and install the choke housing attaching screws. Install the fast idle cam retainer. Install the thermostatic spring housing.

AIR HORN

Refer to Fig. 23 for the correct location of the parts.

1. If the choke plate shaft was removed, position the shaft in the air horn, then install the choke plate rod on the end of the choke shaft.
2. If the choke plate was removed, insert the choke plate into the choke plate shaft. Install the choke plate screws snug, but not tight. Check for proper plate fit, binding in the air horn and free rotation of the shaft by moving the plate from the closed position to the open position. If necessary, remove the choke plate and grind or file the plate edge where it is binding or scraping on the air horn wall. If the choke plate and shaft moves freely, tighten the choke plate screws while holding the choke in the fully closed position. Stake the screws. **When staking the screws, support shaft and plate on a block of wood or a metal bar to prevent bending of the shaft.**
3. Position the main body gasket and the choke rod plastic seal on the main body. Position the air horn on the main body and gasket so that the choke plate rod fits through the seal and the opening in the main body.
4. Insert the end of the choke plate rod into the automatic choke lever. Install the air horn attaching screws and the carburetor identification tag. Tighten the attaching screws. Install the choke plate rod retainer. Install the air cleaner anchor screw. Tighten the air cleaner anchor screw to the specified torque.
5. Perform the automatic choke plate clearance adjustment after the carburetor has been installed on the vehicle. **Perform the required performance adjustments.**
6. After the specified air-fuel is obtained, install the idle mixture limiter caps.

DESCRIPTION

CARBURETOR

The Model 2300 2-V carburetor used on the 330 and 361 CID engines (Fig. 1) has four main assemblies. They are the main body, throttle body, metering block and the fuel bowl. The fuel passages are identified in Fig. 2.

Vehicles equipped with a Model 2300 carburetor have a modulated power valve system. When the throttle plates are closed, the passage to the power valve is shut off. As the throttle plates open, a passage drilled in the throttle plate shaft begins to align with the passage in the main body to partially open the valve. As power demand increases, the passage in the shaft continues to align with the power valve passage until it is fully open at approximately 50 degrees of throttle plate travel.

A manual choke is used on all vehicles.

GOVERNOR

The operation of the throttle actuating unit of the vacuum operated governor system which is installed on the carburetor, is covered in Part 23-20.

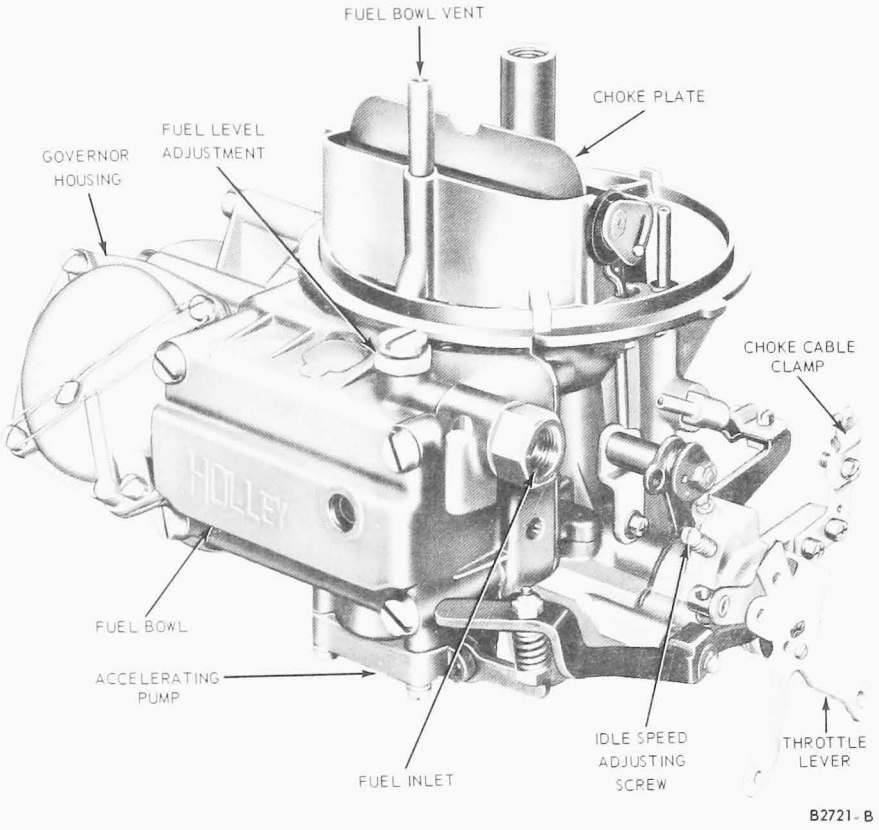

FIG. 1 Model 2300 2-V Carburetor for the 330 and 361 CID Engines Left Front View

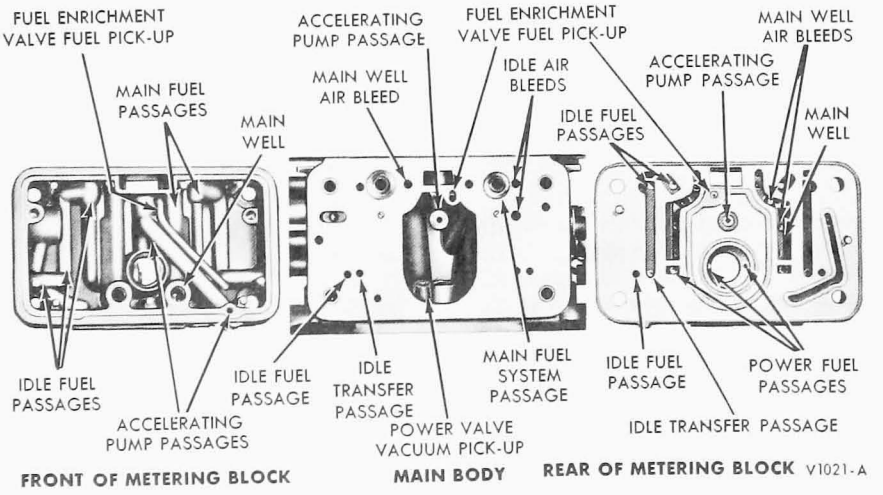

FIG. 2 Fuel Passages Identification

ADJUSTMENTS

FAST IDLE SPEED—INITIAL SETTING

If the carburetor was removed from the vehicle for replacement or overhaul procedures, it is recommended that an initial fast idle adjustment be performed as follows.

1. With the throttle plates closed and the choke plate wide open, measure the clearance between the fast idle cam and the fast idle screw (Fig. 3).
2. If the clearance is not to specifications, turn the fast idle screw the required amount to increase or decrease the clearance. A 1/4 turn in or out will alter the clearance by approximately 0.008 inch.

FAST IDLE SPEED—FINAL SETTING

A hand (cable) operated throttle control has been provided for the engines in various vehicle models and series. The throttle is actuated by a knob, located on the instrument panel. The hand operated throttle control is useful for maintaining constant engine speed when running power take-off equipment or when performing certain service operations.

The fast (cold engine) idle speed is adjusted with the hand throttle control knob pushed fully inward. The idle (hot engine) speed must be adjusted to specifications before the fast idle speed can be adjusted.

The fast idle speed adjustment screw for the carburetor is located in the throttle operating housing (Fig. 3).

The fast idle adjustment screw contacts the fast idle cam during the engine warm-up period and controls the fast (cold engine) idle speed.

1. Adjust the idle (hot engine) speed and mixture to specifications before attempting to set the fast (cold engine) idle speed. **The fast idle speed adjustment is made with the engine at normal, stabilized operating temperature.**
2. With the engine operating and a tachometer attached to the engine, disconnect the choke cable housing from the choke cable bracket clamp. Pull the choke cable housing rearward until the choke plate operating lever is against the stop on the choke cable bracket. **Hold the choke plate open to the choke pulldown limit, to keep the engine running.**

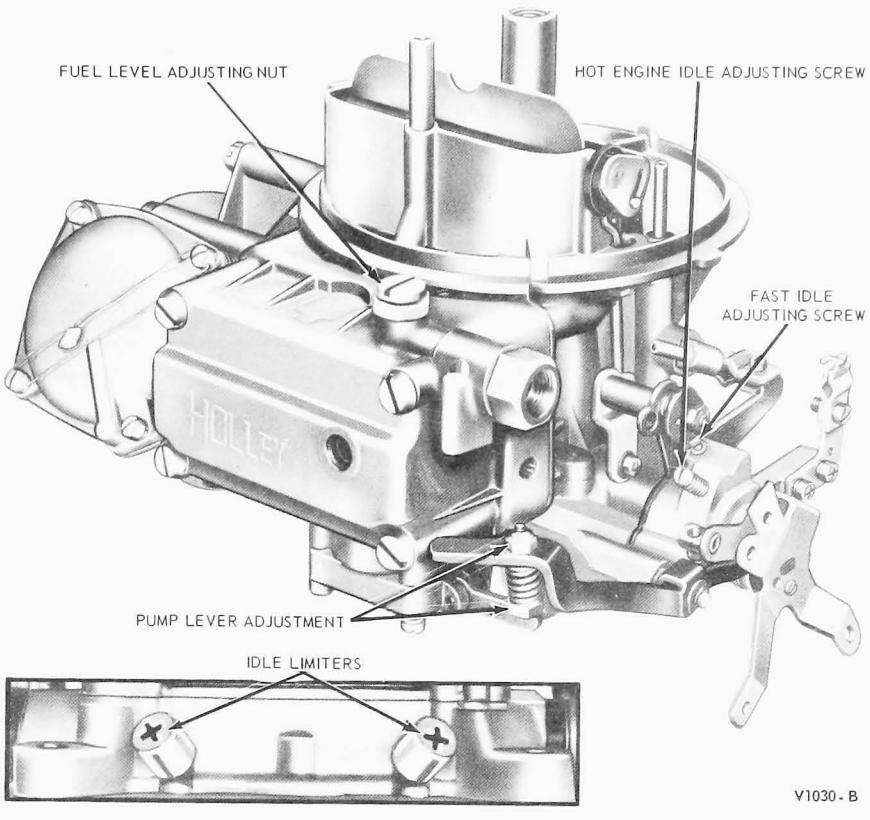

FIG. 3 Carburetor Adjustments

3. Check the fast (cold engine) rpm. If the idle rpm is not to specification, turn the fast idle screw clockwise with a 3/16 inch wrench to decrease the engine rpm or counterclockwise to increase the rpm.
4. Turn off the engine and remove the tachometer.
5. Push the choke lever, cable and housing forward to the full choke position and clamp the choke cable housing to the choke cable bracket.
6. Install the air cleaner assembly if other adjustments are not required.

ACCELERATING PUMP LEVER ADJUSTMENT

1. Using a feeler gauge and with the throttle plates in the wide open position, there should be the specified clearance between the accelerating pump operating lever adjustment screw head and the pump arm when the pump arm is depressed manually (Fig. 4).
2. If adjustment is required, loosen the adjusting screw lock nut and turn the adjusting screw into increase the clearance and out to decrease the clearance. **One half turn of the adjusting screw is equal to approximately 0.015 inch.** When the proper adjustment has been obtained hold the adjustment screw in position with a wrench and tighten the lock nut.
3. Perform an accelerating pump stroke adjustment, if required.

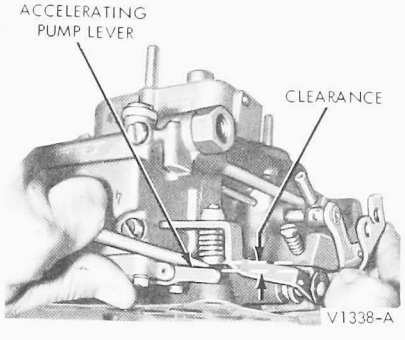

FIG. 4 Accelerating Pump Lever Clearance

ACCELERATING PUMP STROKE ADJUSTMENT

The accelerating pump stroke has been set to help keep the exhaust

emission level of the engine within the specified limits. The additional holes provided for pump stroke adjustment are for adjusting the stroke for specific engine applications. **The stroke should not be changed from the specified setting.**

If the pump stroke has been changed from the specified setting refer to the following instructions to correct the stroke to specifications.

If a change in the adjustment is required, make certain the proper hole (top or bottom) in plastic accelerating pump cam, located behind the throttle lever, is properly aligned (indexed) with the numbered hole (top or bottom) in the throttle lever before installing the retaining screw.

FUEL ENRICHMENT SYSTEM ADJUSTMENT

The following procedure is to be performed only when there is engine backfire.

1. Operate the engine until normal operating temperature has been reached, then turn the engine off.
2. Remove the air cleaner assembly. Install a manifold vacuum gauge and a tachometer on the engine.
3. Turn the fuel enrichment piston adjusting screw in (clockwise) until the head of the screw is flush with the cast boss (Fig. 5). This is to assure that the piston is in the open position.
4. Start the engine and adjust the engine idle speed and idle fuel mixture to obtain the best possible idle smoothness and the maximum intake manifold vacuum possible at the specified idle (hot engine) rpm. Record the vacuum reading.
5. Slowly turn the fuel enrichment adjusting screw out (counterclockwise) until the manifold vacuum drops and/or the engine begins to run rough. This will occur when the lowered spring tension allows the piston to close.
6. Turn the adjusting screw in an additional number of turns, as specified in Fig. 6, according to the maximum manifold vacuum reading recorded in Step 4.
7. Remove the test instruments, install the air cleaner assembly and road test the vehicle for proper anti-backfire control. Decelerate the engine from the highest legal speed limit available to 20 mph, with the transmission in high gear.

If popping is still evident, turn the piston adjusting screw outward (counterclockwise), in increments of 1/4 turn. Repeat the deceleration test after each adjustment until popping noises are no longer evident, or until the adjusting screw has been backed out to within 1/2 turn of the additional turns made in Step 6. For example, if the screw was turned inward 2 turns in Step 6, then it is permissible to turn the screw outward up to 1 1/2 turns when testing for popping. **Do not back the screw out far enough to affect engine idle.**

8. If popping cannot be eliminated following this procedure, then the cause is elsewhere in the exhaust system or in the carburetor metering systems.

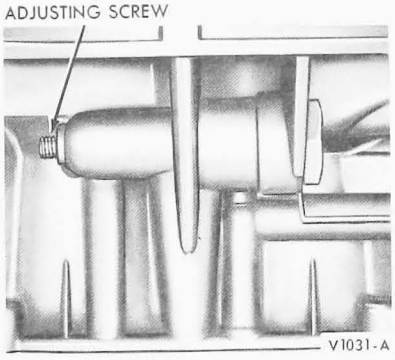

FIG. 5 Fuel Enrichment System Adjustment

Vacuum Reading	Number of Turns on Screw

CV1339-A

FIG. 6 Fuel Enrichment Adjusting Data

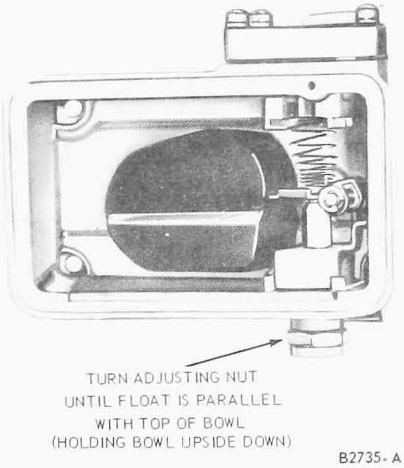

FIG. 7 Adjusting Float—Dry

FUEL LEVEL FLOAT ADJUSTMENT—DRY

The dry float adjustment is a preliminary fuel level adjustment only. The final adjustment (Fuel Level Float Adjustment—Wet) must be performed after the carburetor is installed on the engine.

With the fuel bowl and float assembly removed, adjust the float so that the float is parallel to the fuel bowl, with the top of the fuel bowl inverted (Fig. 7).

FUEL LEVEL ADJUSTMENT—WET

The fuel pump pressure and volume must be to specifications prior to performing the following adjustments.

1. Operate the engine to normalize engine temperatures and place the vehicle on a flat surface, as near level as possible. Stop the engine and remove the air cleaner, if it was not previously removed.
2. Check the fuel level in each fuel bowl separately (Fig. 8). **Place a suitable container below the fuel level sight plug in the fuel bowl to collect any spillover of fuel. Carefully remove the fuel level sight plug and gasket.**
3. If the fuel level is satisfactory, install the sight plug.
4. If the fuel level is too high, drain the fuel bowl and refill it. To drain the fuel bowl, loosen one lower retaining bolt from the fuel bowl and drain the fuel into a suitable container. Check the fuel level again before altering the float setting. **This will eliminate the possibility of foreign material causing a temporary flooding condition. Install the bolt and the fuel level sight plug, and start the engine to fill the fuel bowl. After the fuel level has stabilized, stop the engine and check the fuel level.**

If the fuel level is still too high, it should first be lowered below specifications and then raised until it is just at the lower edge of the sight plug opening. If the fuel level is too low, it is only necessary to raise it to the specified level. Follow the procedure under To

Lower Fuel Level or To Raise Fuel Level, whichever is applicable.

TO LOWER FUEL LEVEL

1. With the engine stopped, loosen the lock screw on top of the fuel bowl just enough to allow rotation of the adjusting nut underneath (Fig. 8). **Do not loosen the lock screw or attempt to adjust the fuel level with the sight plug removed and the engine running because the pressure in the line will spray fuel out and present a fire hazard.**
2. Turn the adjusting nut approximately 1/2 turn in to lower the fuel level below specifications (1/6 turn of the adjusting nut, depending on the direction of rotation, will raise or lower the float assembly at the fuel level sight plug opening 3/64 inch).
3. Tighten the lock screw and install the fuel level sight plug. Start the engine. After the fuel level has stabilized, stop the engine and check the fuel level at the sight plug opening. The fuel level should be below specified limits. If it is not, repeat the previous steps, turning the adjusting nut an additional amount sufficient to lower the fuel below the specified level.
4. Loosen the lock screw and turn the adjusting nut out in increments of 1/6 turn or less until the correct fuel level is achieved. After each adjustment, tighten the lock screw, install the fuel level sight plug, and then start the engine and stabilize the fuel level . Check the fuel level at the sight plug opening. Install the sight plug and gasket.
5. Install the air cleaner if other carburetor adjustments are not required.

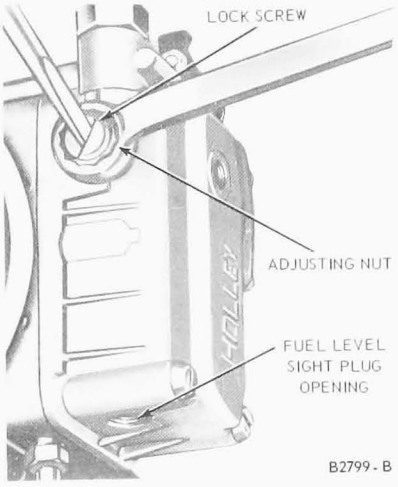

FIG. 8 Adjusting Fuel Level

TO RAISE FUEL LEVEL

Perform steps 1, 4 and 5 under the procedure, To Lower Fuel Level.

REMOVAL AND INSTALLATION

CARBURETOR

Removal

1. Remove the air cleaner. Remove the throttle rod from the throttle lever. Disconnect the choke control cable, hand throttle control cable, the distributor vacuum hose and the fuel line.
2. Disconnect the governor throttle control lines or rod at the carburetor.
3. Remove the carburetor retaining nuts and lockwashers, then remove the carburetor. Remove the spacer from the manifold.

Installation

1. Be sure all old gasket material is removed from the manifold heat riser flange, then place the spacer in position on the manifold. Position the carburetor on the manifold and install the lockwashers and nuts. Tighten the nuts alternately to specification.
2. Connect the throttle rod. Connect the choke control cable. **Be sure the end of the choke cable is bent downward to prevent interference with the bottom of the air cleaner. This interference will restrict opening of the choke plate.** Connect the hand throttle control cable, the distributor vacuum hose, the fuel line, and the governor lines or control rod. Adjust the idle speed, the primary and secondary fuel level, and the idle fuel mixture. Adjust the governor control rod.

FUEL BOWL AND GASKET AND METERING BLOCK AND GASKET

Removal

1. Remove the fuel inlet line and vacuum line.
2. Place a suitable container under the fuel bowl and drain the bowl by loosening one of the lower fuel bowl retaining screws. Remove the container.
3. Remove the four fuel bowl retaining screws.
4. Remove the fuel bowl, gasket and baffle, and metering block and gasket. Discard the gaskets.

Installation

1. If the fuel bowl or metering block is being replaced, transfer the parts.
2. Position the metering block gasket on the dowels on the back of the metering block.
3. Lay the metering block in place on the main body.
4. Position the baffle and fuel bowl gasket on the metering block.
5. Place the fuel bowl on the metering block. Use new compression gaskets on the bowl retaining screws; then install and tighten the screws.

POWER VALVE AND GASKET

Removal

1. Remove the fuel bowl and metering block.
2. Using a socket wrench, remove the power valve and gasket.
3. Discard the gasket.

Installation

1. Place a new gasket on the specified power valve.
2. Using a socket wrench, install the power valve and gasket.
3. Install the fuel bowl and metering block.

MAIN JET

1. Remove the fuel bowl and metering block.
2. Use a jet wrench to remove and install jets.
3. Install the fuel bowl and metering block.

ACCELERATING PUMP DIAPHRAGM

Removal

1. Remove the fuel bowl and metering block.
2. Remove the accelerating pump cover, diaphragm and spring.

Installation

1. Place the spring and diaphragm in the accelerating pump chamber. The diaphragm must be positioned so that the diaphragm disc protrudes from the fuel bowl.
2. Install the cover screws finger tight.
3. Make sure the diaphragm is centered, compress the diaphragm with the pump operating lever and tighten the cover screws.

FLOAT

Removal

1. Using needle nose pliers, remove the float retainer.
2. Slide the float off the shaft.
3. Remove the spring from the float.

Installation

1. Install the float spring on the float.
2. Slide the float on the shaft.
3. Install the float retainer.

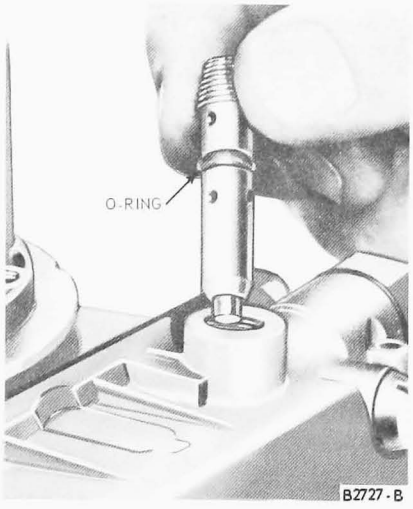

FIG. 9 Removing Fuel Inlet Needle and Seat

FUEL INLET NEEDLE AND SEAT

Removal

The fuel inlet needle and seat assembly can be replaced without removing the fuel bowl.

1. Remove the air cleaner.
2. Remove the fuel level adjustment lock screw and gasket. Turn the adjusting nut out and remove the adjusting nut and gasket. Remove the fuel inlet needle and seat assembly (Fig. 9). **Do not disassemble the fuel inlet needle and seat assembly. They are matched parts and are serviced as an assembly.**

Installation

1. Position the fuel inlet needle and seat assembly in the fuel bowl.
2. Position the adjusting nut gasket and nut on the fuel inlet needle and seat assembly. Align the flat on the ID of the nut with the flat on the OD of the fuel inlet needle and seat assembly.
3. Install the fuel level adjustment lock screw and gasket.
4. Adjust the fuel level.

DISASSEMBLY AND ASSEMBLY

DISASSEMBLY

To facilitate working on the carburetor and to prevent damage to the throttle plates, install bolts about 2 1/4 inches long of the correct diameter through the carburetor attaching bolt holes with a nut above and below the flange (or install carburetor legs).

Use a separate container for the component parts of the various assemblies to facilitate cleaning, inspection and assembly.

The following is a step-by-step sequence of operations for completely overhauling the carburetor; however, certain components of the carburetor may be serviced without disassembling the entire unit. For a complete carburetor overhaul, follow all the steps. To partially overhaul the carburetor or to install a new gasket kit, follow only the applicable steps.

FUEL BOWL AND METERING BLOCK

Refer to Fig. 10 for the correct location of the fuel bowl parts.

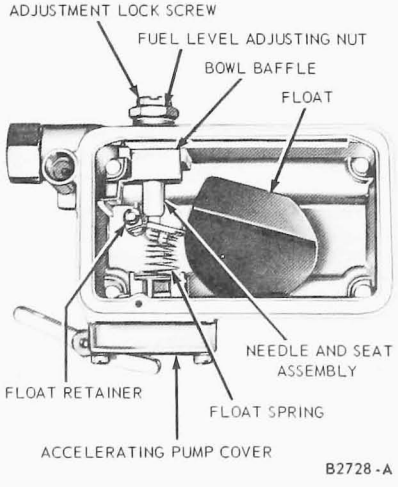

FIG. 10 Fuel Bowl

1. Remove the fuel bowl and gasket, and the metering block and gasket. Discard the gaskets.
2. Using a socket wrench, remove the power valve and gasket (Fig. 11). Discard the gasket. Using a jet wrench, remove the main jets (Fig. 12).
3. Remove the fuel level adjustment lock screw and gasket. Turn the adjusting nut counterclockwise and remove the lock nut and gasket, and the fuel inlet needle and seat assembly. **Do not disassemble the fuel inlet needle and seat. They are matched, and are replaced as an assembly.**
4. Using needle nose pliers, remove the float retainer (Fig. 13).
5. Slide the float off the shaft. Remove the spring from the float.
6. Remove the fuel level sight plug and gasket. Remove the fuel inlet fitting, gasket, and filter screen.
7. Invert the fuel bowl and remove the accelerating pump cover, diaphragm, and spring. The accelerating pump inlet ball check is not removable.

MAIN BODY

1. Remove the governor housing cover.

Remove the nut and lock washer attaching the governor lever to the throttle shaft. Remove the governor housing assembly and seal. Remove the governor housing gasket. Invert the carburetor and remove the throttle body from the main body. Disconnect the choke rod from the choke control shaft lever assembly by pushing the rod toward the main body and releasing it from the lever. Discard the throttle body gasket.

2. Remove the elastic stop nuts from the choke plate and remove the screws, flat spring, spacers, choke plate and the choke plate poppet valve. Remove the choke rod from the choke plate shaft. Slide the choke rod out of the choke shaft as the shaft is removed from the housing. Remove the choke rod seal from the main body.
3. Remove the retainers, spring seats, and springs from the poppet valve on the front of the choke plate housing. **Use caution to avoid losing the springs as they are under compression.** Remove the pins and poppet valve.
4. Remove the accelerating pump discharge nozzle from the main body.
5. Invert the main body and let the accelerating pump discharge needle fall into the hand (Fig. 14).

THROTTLE BODY

1. Remove the accelerating pump operating lever and the throttle operating shaft housing assembly and gasket. Remove the throttle operating shaft housing back-up plate and gasket.
2. If it is necessary to remove the throttle plates, lightly scribe both throttle plates along the throttle shaft and mark each throttle plate and its corresponding barrel to insure proper installation (Fig. 15). Remove the throttle plates. Remove the retainer from each end of the shaft. Slide the throttle shaft out of the throttle body.

THROTTLE OPERATING SHAFT HOUSING

1. Remove the engine idle speed adjusting screw and spring. Remove the fast idle adjusting pin and screw.
2. Loosen the throttle lever screw. Remove the throttle lever retaining pin. Remove the throttle lever and the accelerating pump cam. Remove the throttle pick-up lever and swivel assembly.
3. Remove the throttle shaft retainer and slide the throttle shaft out of the housing.

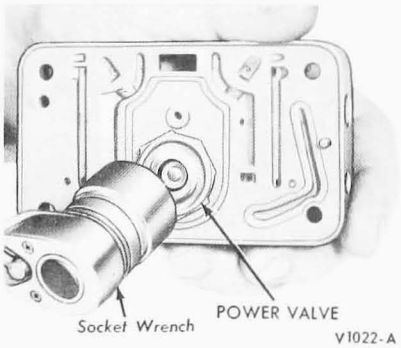

FIG. 11 Removing or Installing Power Valve

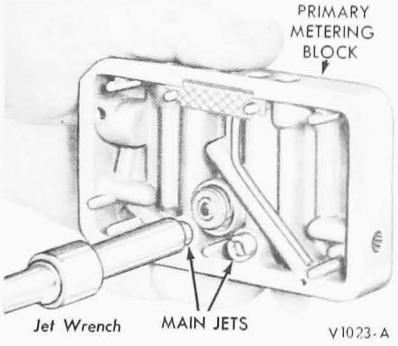

FIG. 12 Removing or Installing Main Jet

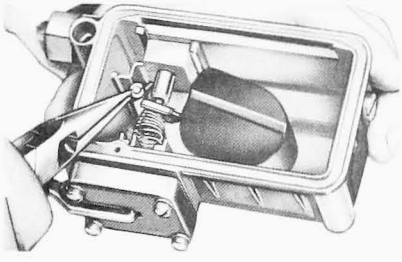

FIG. 13 Removing Float Shaft Retainer

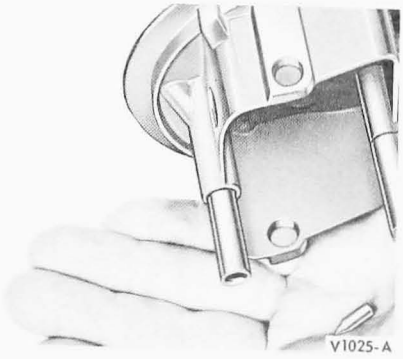

FIG. 14 Removing Acclerating Pump Discharge Needle

GOVERNOR HOUSING

1. Remove the governor spring, remove the diaphragm rod retainer and remove the governor lever.
2. Remove the governor line fitting, by-pass jets, diaphragm cover and the diaphragm.

ASSEMBLY

Make sure all holes in the new gaskets have been properly punched and that no foreign material has adhered to the gaskets. Make sure the accelerating pump diaphragm is not torn or cut. A disassembled view of the carubretor is shown in Fig. 16.

GOVERNOR HOUSING

Refer to Fig. 17 for the correct location of the parts.

1. Install the governor by-pass jets and the governor line fitting. Be sure to install the jets in their correct location. The jet ports are designated on the housing as A (lower port) and B (upper port). Refer to the specifications for the correct jet size.
2. Position the governor diaphragm in the governor housing. Install the cover, then install a new safety wire and seal.
3. Place the governor lever in the housing and position the diaphragm rod on the smallest stud of the governor lever. Install the rod retainer.

THROTTLE OPERATING SHAFT HOUSING

Refer to Fig. 18 for the correct location of the parts.

1. Slide the throttle operating lever and shaft assembly into the housing. Install the accelerating pump cam

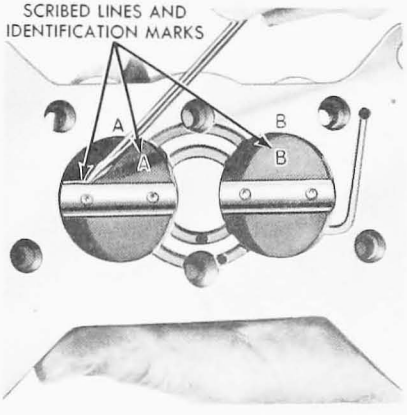

FIG. 15 Removing Throttle Plate

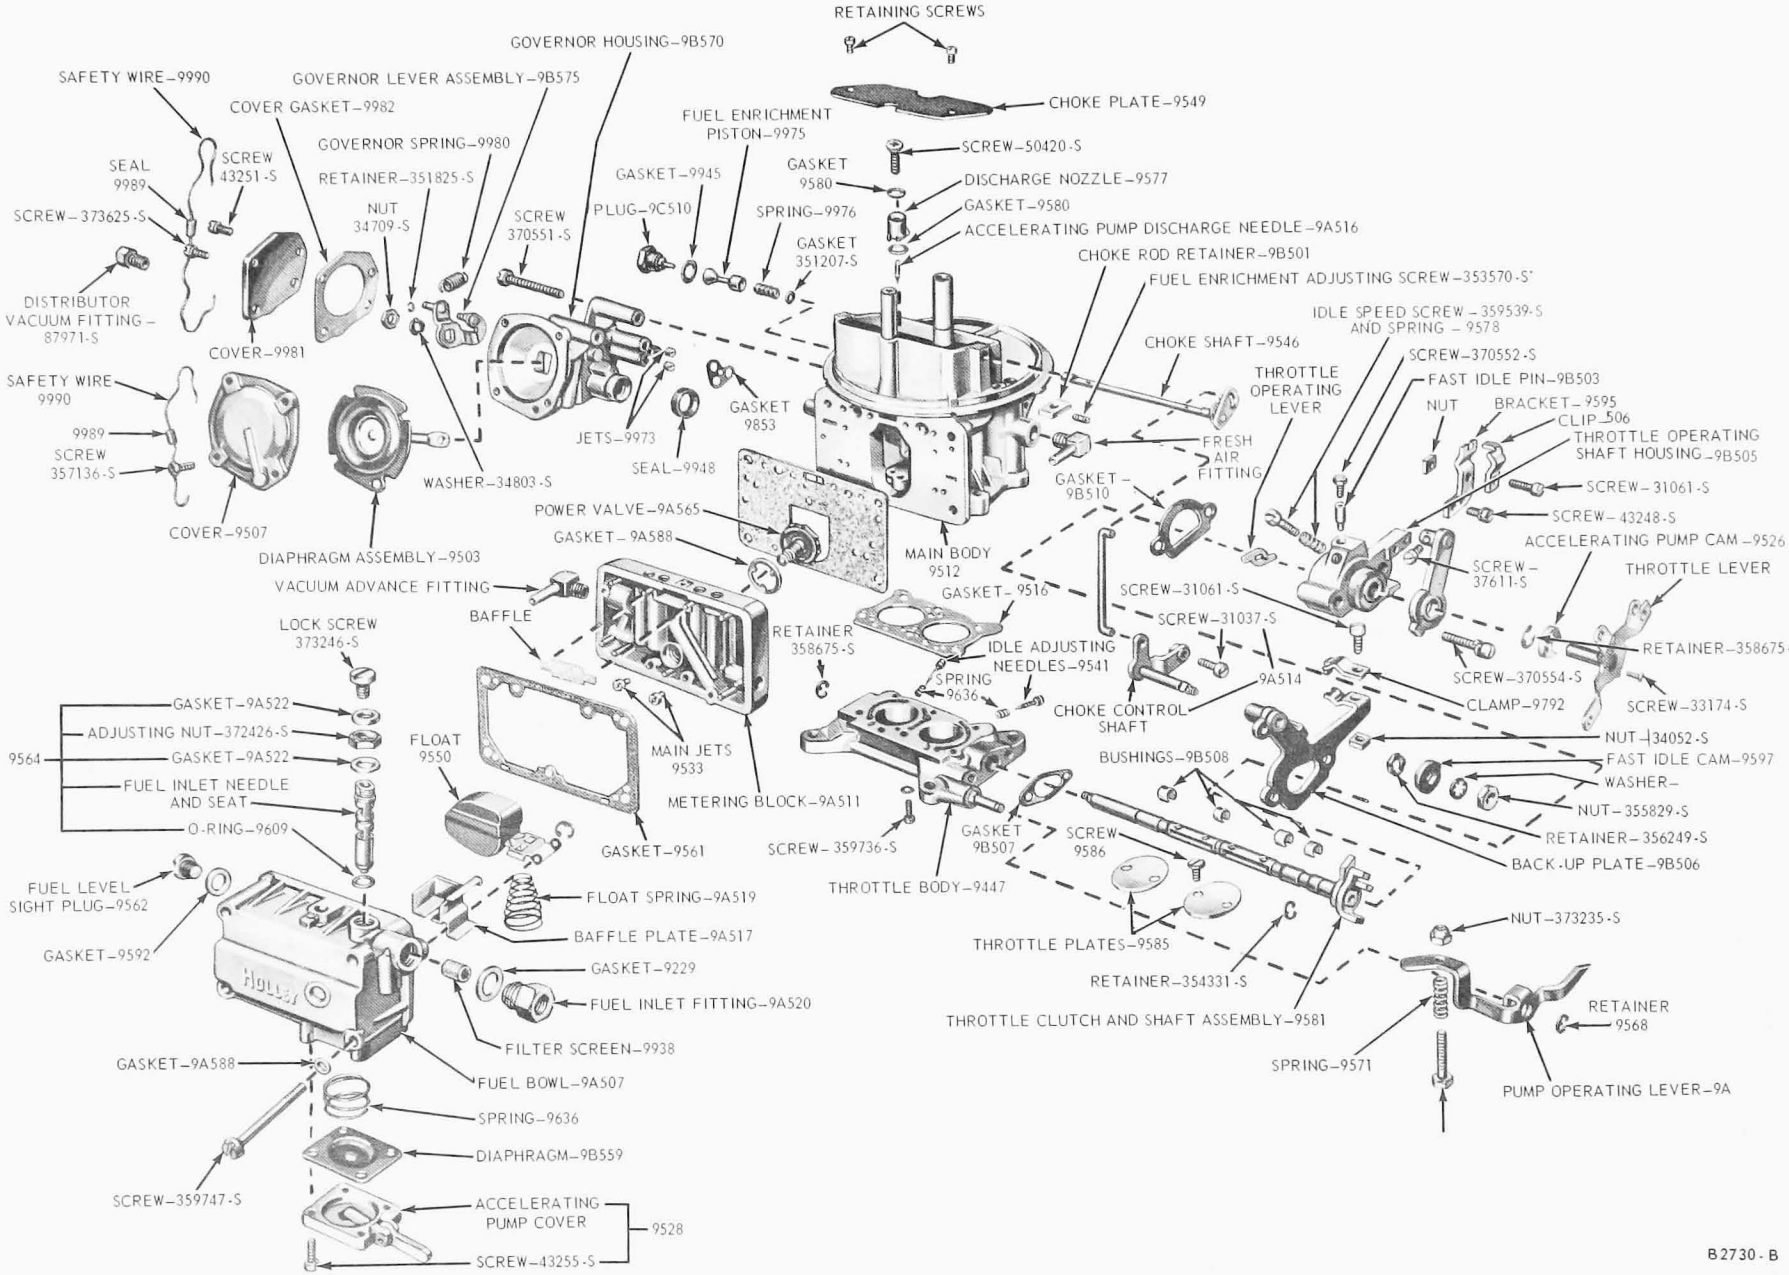

FIG. 16 Carburetor Assembly

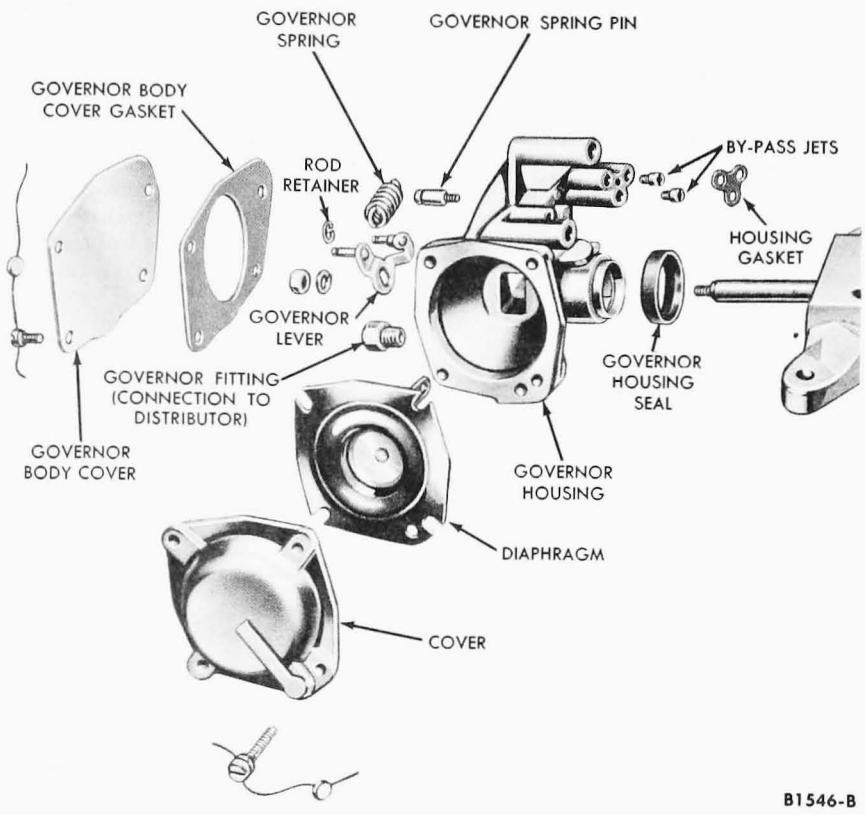

FIG. 17 Governor Housing Assembly

on the throttle lever. Position the pick-up lever and swivel assembly on the shaft.

2. Aligning the retaining pin hole in the throttle lever and shaft, position the throttle lever on the shaft. **Be sure the throttle lever can be rotated from the full open position to the full closed position. Install the throttle lever retaining pin. Install the throttle lever screw.**
3. Install the engine idle speed adjusting screw and spring. Install the fast idle adjusting pin and screw.

THROTTLE BODY

Refer to Fig. 19 for the correct locations of the parts.

1. If the throttle plates were removed, position the bushings on the throttle shaft and slide them into the throttle body. Install the retainer on each end of the shaft. Referring to the lines scribed on the throttle plates, install the plates in their proper location with the screws snug, but not tight. Close the throttle plates and hold the throttle body up to the light. Little or no light should show between the throttle plates and the throttle bores. If the throttle plates are properly installed and there is no

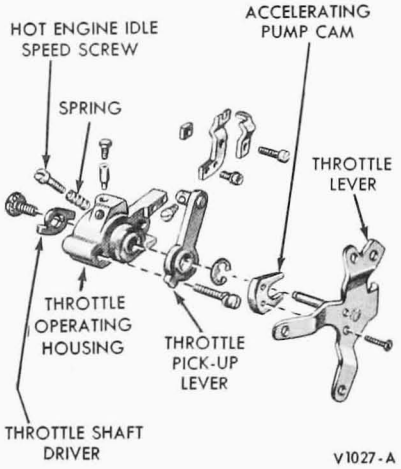

FIG. 18 Throttle Operating Shaft Assembly

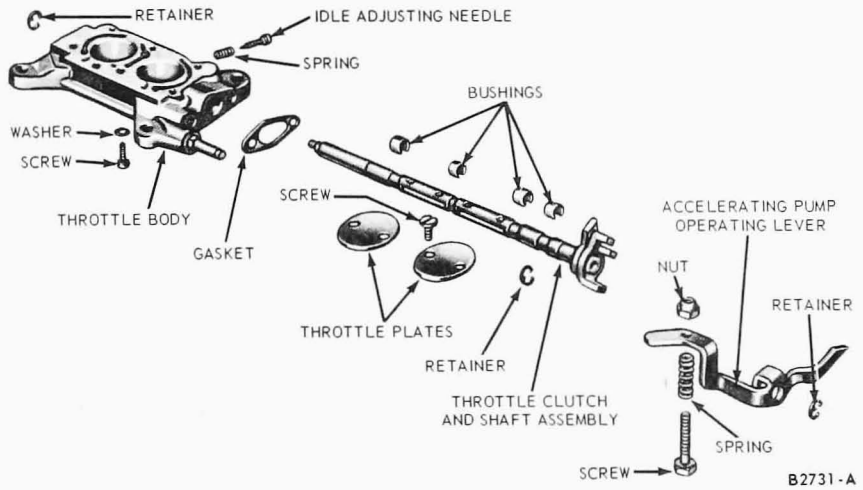

FIG. 19 Throttle Body Assembly

binding when the throttle shafts are rotated, tighten and stake the throttle plate screws.
2. Position the throttle operating shaft housing back-up plate assembly gasket and plate assembly on the throttle body by sliding them over the clutch lever on the throttle shaft.
3. Insert the throttle operating housing attaching screws in the housing. Slide the housing gasket over the screws.
4. Open the throttle plates and install the throttle operating housing on the throttle body. **If the housing is correctly installed, the throttle lever will close the throttle plates, but will not open them.**
5. Install the accelerating pump lever on the throttle body.
6. Install the idle adjusting needles and springs. Turn the needles in gently until they touch the seat, then back them out 1 -1 1/2 turns.

MAIN BODY

1. Drop the accelerating pump discharge needle into the well (Fig. 20). Seat the needle with a brass drift and a light hammer. Make sure it is free. Position the accelerating pump discharge nozzle gasket and nozzle in the main body; then install the attaching screw and gasket.
2. Place the choke rod seal in the groove located on the underside of the carburetor air cleaner flange.
3. Working from the underside of the carburetor air cleaner flange, slide the choke rod (with the small upset end of the top) through the opening in the main body and rod seal.
4. Place the air horn poppet valve in position on the main body. From inside the air horn, insert the pins through the main body and poppet valve. Install the spring, spring seats, and retainers.
5. Position the choke plate shaft in the air horn. Position the choke rod in the choke plate shaft lever and override spring.
6. Position the choke plate poppet valve over the retaining screws, then position the choke plate on top of the poppet valve.
7. Place the spacers over the screws, then position the flat spring over the screws so that the curved portion is down. Install the attaching nuts.
8. Invert the main body and position the gasket on the main body. Place

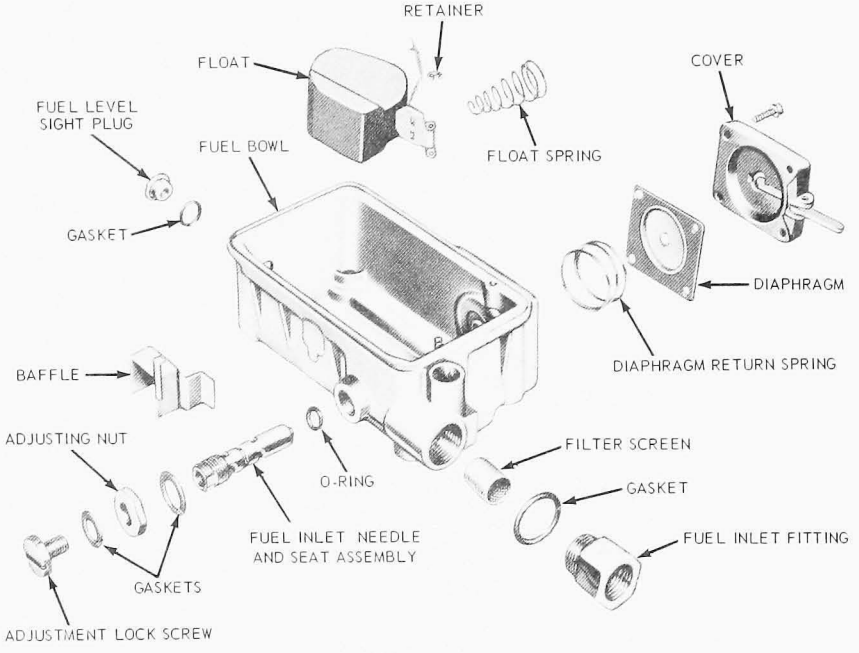

FIG. 21 Fuel Bowl Assembly

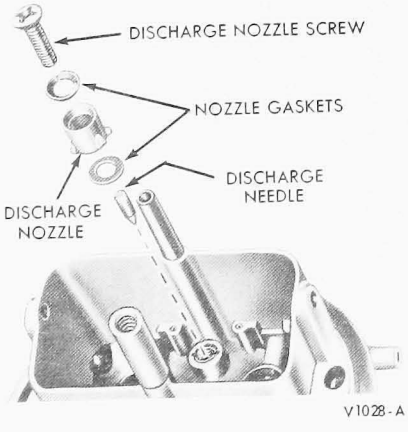

FIG. 20 Accelerating Pump Discharge Needle Installation

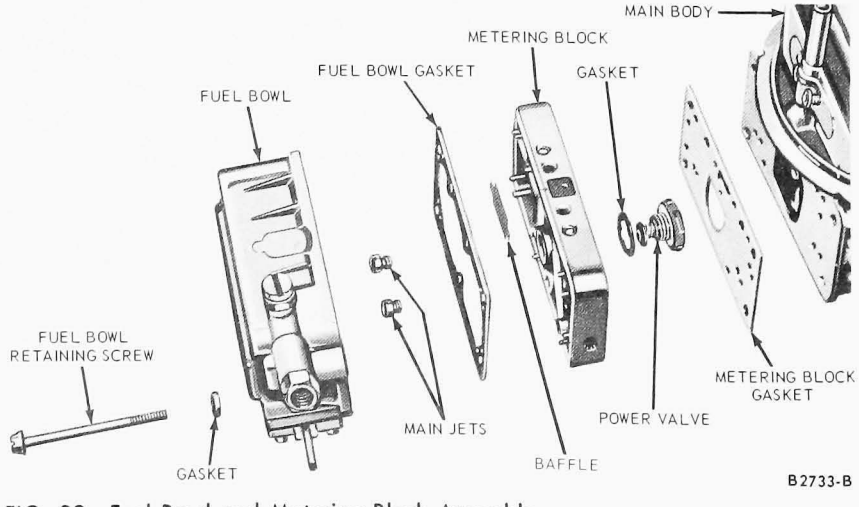

FIG. 22 Fuel Bowl and Metering Block Assembly

the throttle body in position on the main body sliding the choke rod into the choke rod lever as the throttle body is placed into position. Install the throttle body to main body screws and lockwashers.

9. Install the governor housing seal on the governor housing. Place the housing gasket on the main body.
10. Position the governor housing in place on the throttle body and main body. Place the governor lever over the throttle shaft and install the washer and nut. Install the governor housing attaching screws.
11. Install the governor spring. Install the housing gasket and cover. Install the cover safety wire and seal.

FUEL BOWL AND METERING BLOCK

Refer to Figs. 21 and 22 for the correct location of the fuel bowl parts.

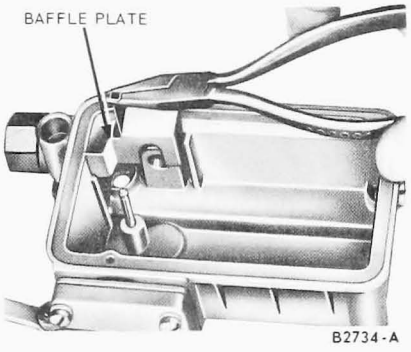

FIG. 23 Baffle Plate Installation

1. Place the accelerating pump diaphragm spring and diaphragm in the accelerating pump chamber. The diaphragm must be positioned so that the large end of the lever disc will be against the operating lever. Install the cover with the screws finger tight. Make sure the diaphragm is centered, then compress the diaphragm with the pump operating lever and tighten the cover screws.
2. Install the fuel level sight plug and gasket.
3. Install the fuel inlet filter screen, gasket, and fitting.
4. Slide the baffle plate on the ridges in the fuel bowl (Fig. 23).
5. Install the float spring on the float, slide the float on the shaft and install the float retainer.
6. Apply petroleum jelly to a new O-ring seal and slide it on the fuel inlet needle and seat assembly.
7. Position the fuel inlet needle and seat assembly in the fuel bowl through the top of the bowl. Position the adjusting nut gasket and nut on the fuel inlet needle and seat. Align the flat on the ID of the nut with the flat on the OD of the fuel inlet needle and seat assembly.
8. As a preliminary float adjustment, adjust the float so that the top of the float is parallel with the top of the fuel bowl with the fuel bowl inverted (Fig. 24).
9. Install the fuel level adjusting lock screw and gasket.
10. Using a socket wrench, install the power valve and a new gasket. **Be sure to install the correct power valve. Refer to the specifications for the correct identification number. The number is stamped on a flat on the base of the valve** Using a jet wrench, install the main jets.
11. Position the metering block gasket on the dowels on the back of the metering block. Lay the metering block in place on the main body. Position the baffle on the metering block, then position the fuel bowl gasket on the metering block. Place the attaching screws and new compression gaskets in the fuel bowl. Lay the bowl in place on the metering block. Tighten the screws.

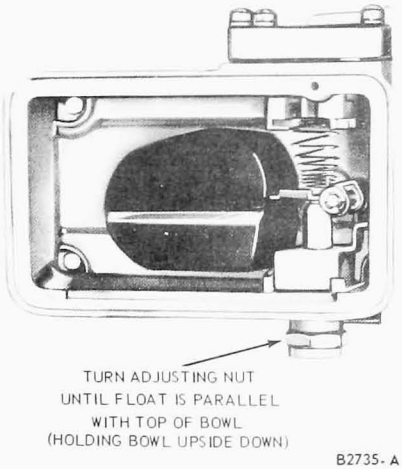

FIG. 24 Float Adjustment

DESCRIPTION

The 4-V carburetor used on the 391, 401, 477 and 534 CID engines (Figs. 1 and 2) is a downdraft, two-stage carburetor. It can be considered as two dual carburetors; one supplying a fuel-air mixture throughout the entire range of engine operation (primary stage), and the other functioning only when a greater quantity of fuel-air mixture is required (secondary stage).

The primary stage (front section) of the carburetor contains a fuel bowl, metering block (Fig. 3), and an accelerating pump assembly. The primary barrels each contain a primary and booster venturi, main fuel discharge nozzle, throttle plate, and idle fuel passage. The choke plate, mounted in the air horn above the primary stage venturis, is manually controlled.

On the carburetor for the 401, 477 and 534 engines, poppet or blow-by valves are located in the choke plate and at the front of the primary air horn.

The secondary stage, (rear section) of the carburetor contains a fuel bowl, metering block, and secondary throttle operating diaphragm assembly. The secondary barrels each contain a primary and booster venturi, idle fuel passages, main secondary fuel discharge nozzle, throttle plate, and a transfer system fuel passage.

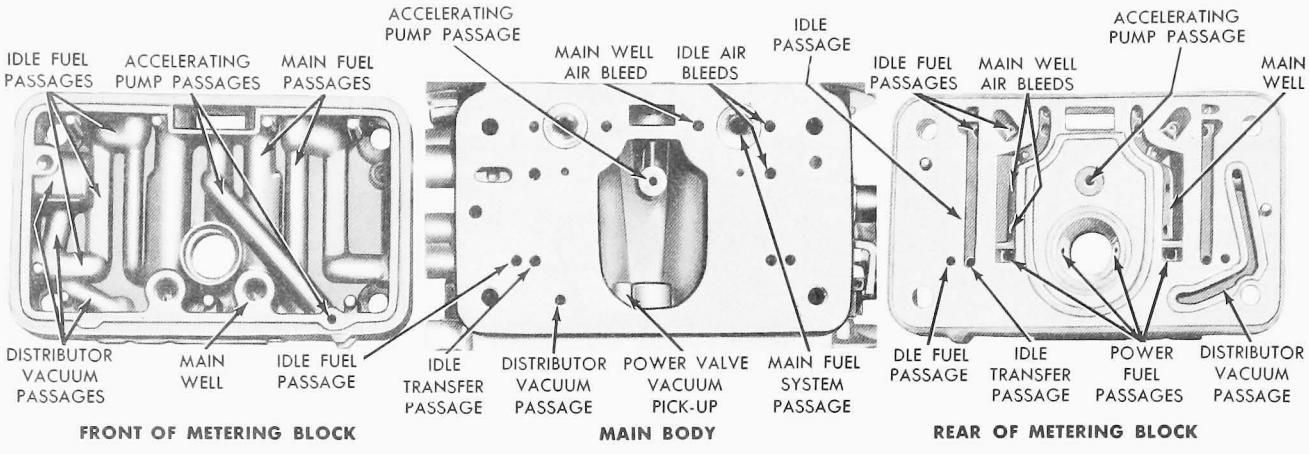

FIG. 3 Fuel Passages Identification—Holley 4-V

ADJUSTMENTS

FAST IDLE SPEED ADJUSTMENT—INITIAL SETTING

391 4-V ENGINE

1. With the primary throttle plates closed, measure the clearance between the fast idle cam and the head of the fast idle screw (Fig. 4).
2. If the clearance is not to specifications, remove the governor housing, following the removal procedure in Part 23-20.
3. Turn the fast idle screw the required amount to increase or decrease the clearance. A **3/16 inch wrench with a 90 degree head will be required to perform the adjustment.** A 1/4 turn in or out will alter the clearance by approximately 0.008 inch.
4. Install the housing on the carburetor governor and check the clearance, as outlined in Step 1. When the clearance is properly adjusted, install the governor housing, following the installation procedure in Part 23-20.

401, 477 AND 534 4-V ENGINES

With the choke in the wide open position, turn the fast idle adjusting screw (Fig. 5) in until it just touches the fast idle cam; then back it off 1/8 to 1/4 turn.

FAST IDLE SPEED—FINAL SETTING

A hand (cable) operated throttle control has been provided for the engines in various vehicle models and series. The throttle is actuated by a knob, located on the instrument panel. The hand operated throttle control is useful for maintaining constant engine speed when running power take-off equipment or when performing certain service operations.

The fast (cold engine) idle speed is adjusted with the hand throttle control knob pushed fully inward. The idle (hot engine) speed must be adjusted to specification before the fast idle speed can be adjusted.

391 (4-V) V-8 ENGINES

The fast idle speed adjustment screw for the 391 (4-V) V-8 engine is located in the governor housing (Fig. 4).

The fast idle adjustment screw contacts the fast idle cam during the engine warm-up period and controls the fast (cold engine) idle speed.

1. Adjust the idle (hot engine) speed and mixture to specifications before attempting to set the fast (cold engine) idle speed. **The fast idle speed adjustment is made with the engine at normal, stabilized operating temperature.**
2. With the engine operating and a tachometer attached to the engine, disconnect the choke cable housing from the choke cable bracket clamp. Pull the choke cable housing rearward until the choke plate operating lever is against the stop on the choke cable bracket. **Hold the choke plate open to the choke**

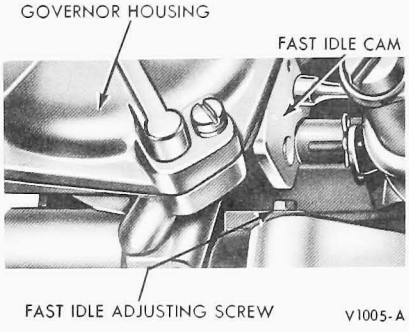

FIG. 4 Fast Idle Speed Adjustment—391 Engine

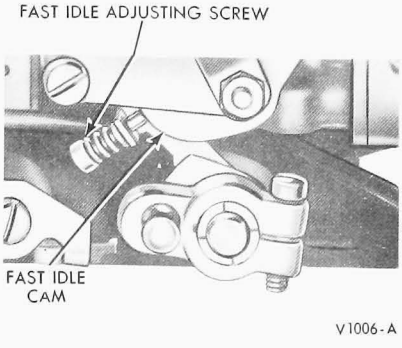

FIG. 5 Fast (Cold) Idle Speed Adjustment— 401, 477 and 534 CID Engines

pulldown limit, to keep the engine running.

3. Check the fast (cold engine) rpm. If the idle rpm is not to specification, turn the fast idle screw clockwise with a 3/16 inch wrench to decrease the engine rpm or counterclockwise to increase the rpm. **A 3/16 inch wrench with a 90 degree head will be required to perform the adjustment.**
4. Turn off the engine and remove the tachometer.
5. Push the choke lever, cable and housing forward to the full choke position and clamp the choke cable housing to the choke cable bracket.
6. Install the air cleaner assembly if other adjustments are not required.

401, 477 AND 534 (4-V) V-8 ENGINES

The fast idle adjustment screw on the left side of the carburetor contacts the fast idle cam during the engine warm-up period and controls the fast (cold engine) idle speed (Fig. 5).

1. Adjust the idle (hot engine) speed and mixture before attempting to set the fast (cold engine) idle speed. **The fast idle speed adjustment is made with the engine at a normal, stabilized operating temperature.**
2. With the choke in the wide open position, turn the fast idle adjusting screw (Fig. 5) in until it just touches the fast idle cam; then back it off 1/8 to 1/4 turn.

ACCELERATING PUMP LEVER ADJUSTMENT

1. Using a feeler gauge and with the throttle plates (primary throttle plates) in the wide open position, there should be the specified clearance between the accelerating pump operating lever adjustment screw head and the pump arm when the pump arm is depressed manually (Fig. 6).
2. If adjustment is required, loosen the adjusting screw lock nut and turn the adjusting screw in to increase the clearance and out to decrease the clearance. **One half turn of the adjusting screw is equal to approximately 0.015 inch.** When the proper adjustment has been obtained hold the adjustment screw in position with a wrench and tighten the lock nut.
3. Perform an accelerating pump stroke adjustment, if required.

ACCELERATING PUMP STROKE ADJUSTMENT

The accelerating pump stroke has been set to help keep the exhaust emission level of the engine within the specified limits. The additional holes provided for pump stroke adjustment are for adjusting the stroke for specific engine applications. **The stroke should not be changed from the specified setting.**

If the pump stroke has been changed from the specified setting refer to the following instructions to correct the stroke to specifications.

If a change in the adjustment is required, make certain the proper hole (top or bottom) in plastic accelerating pump cam, located behind the throttle lever, is properly aligned (indexed) with the numbered hole (top or bottom) in the throttle lever before installing the retaining screw.

FUEL LEVEL FLOAT ADJUSTMENT—DRY

The dry float adjustment is a preliminary fuel level adjustment only. The final adjustment (Fuel Level Float Adjustment—Wet) must be performed after the carburetor is installed on the engine.

With the fuel bowls and floats assemblies removed, adjust the floats so that the floats are parallel to the fuel bowls, with the top of the fuel bowls inverted (Fig. 7).

FUEL LEVEL ADJUSTMENT—WET

The fuel pump pressure and volume must be to specifications prior to performing the following adjustments.

1. Operate the engine to normalize engine temperatures and place the vehicle on a flat surface, as near level as possible. Stop the engine and remove the air cleaner, if it was not previously removed.
2. Check the fuel level in each fuel bowl separately (Fig. 8). **Place a suitable container below the fuel level sight plug in the fuel bowl to collect any spillover of fuel. Carefully remove the fuel level sight plug and gasket. Check each fuel bowl separately. The fuel level within the bowl should be at the lower edge of the sight plug opening (plus or minus 1/16 inch).**
3. If the fuel level is satisfactory, install the sight plug.
4. If the fuel level is too high, drain the fuel bowl and refill it. To drain the fuel bowl, loosen one lower retaining bolt from the fuel bowl and drain the fuel into a suitable container. Check the fuel level again before altering the float setting. **This will eliminate the possibility of foreign material**

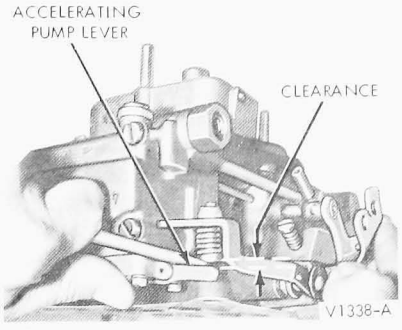

FIG. 6 Accelerating Pump Lever Clearance—Holley Carburetors

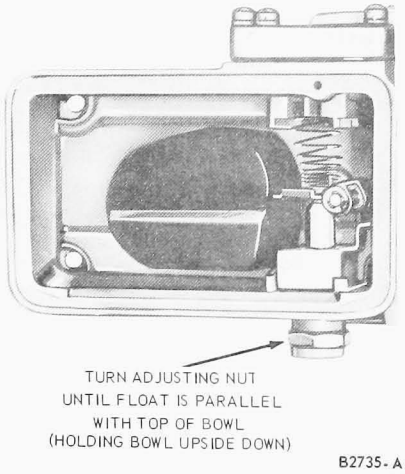

FIG. 7 Adjusting Float—Dry

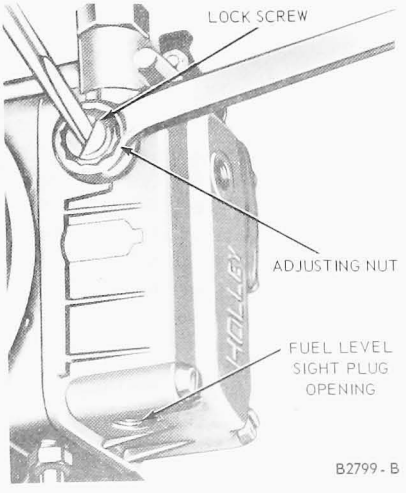

FIG. 8 Adjusting Fuel Level

causing a temporary flooding condition. Install the bolt and the fuel level sight plug, and start the engine to fill the fuel bowl. After the fuel level has stabilized, stop the engine and check the fuel level.

If the fuel level is still too high, it should first be lowered below specifications and then raised until it is just at the lower edge of the sight plug opening. If the fuel level is too low, it is only necessary to raise it to the specified level. Follow the procedure under To Lower Fuel Level or To Raise Fuel Level, whichever is applicable.

TO LOWER FUEL LEVEL

1. With the engine stopped, loosen the lock screw on top of the fuel bowl just enough to allow rotation of the adjusting nut underneath (Fig. 8). **Do not loosen the lock screw or attempt to adjust the fuel level with the sight plug removed and the engine running because the pressure in the line will spray fuel out and present a fire hazard.**
2. Turn the adjusting nut approximately 1/2 turn in to lower the fuel level below specifications (1/6 turn of the adjusting nut, depending on the direction of rotation, will raise or lower the float assembly at the fuel level sight plug opening 3/64 inch).
3. Tighten the lock screw and install the fuel level sight plug. Start the engine. After the fuel level has stabilized, stop the engine and check the fuel level at the sight plug opening. The fuel level should be below specified limits. If it is not, repeat the previous steps, turning the adjusting nut an additional amount sufficient to lower the fuel below the specified level.
4. Loosen the lock screw and turn the adjusting nut out in increments of 1/6 turn or less until the correct fuel level is achieved. After each adjustment, tighten the lock screw, install the fuel level sight plug, and then start the engine and stabilize the fuel level. Check the fuel level at the sight plug opening. Install the sight plug and gasket.
5. Install the air cleaner if other carburetor adjustments are not required.

TO RAISE FUEL LEVEL

Perform steps 1, 4 and 5 under the procedure, To Lower Fuel Level.

REMOVAL AND INSTALLATION

CARBURETOR

Removal

1. Remove the air cleaner. Remove the throttle rod from the throttle lever. Disconnect the choke control cable, hand throttle control cable, the distributor vacuum hose and the fuel line.
2. Disconnect the governor throttle control lines or rod at the carburetor.
3. Remove the carburetor retaining nuts and lockwashers, then remove the carburetor. Remove the spacer from the manifold.

Installation

1. Be sure all old gasket material is removed from the manifold heat riser flange, then place the spacer in position on the manifold. Position the carburetor on the manifold and install the lockwashers and nuts. Tighten the nuts alternately to specification.
2. Connect the throttle rod. Connect the choke control cable. **Be sure the end of the choke cable is bent downward to prevent interference with the bottom of the air cleaner. This interference will restrict opening of the choke plate.** Connect the hand throttle control cable, the distributor vacuum hose, the fuel line, and the governor lines or control rod. Adjust the idle speed, the primary and secondary fuel level, and the idle fuel mixture. Adjust the governor control rod.

FUEL BOWL AND GASKET AND METERING BLOCK AND GASKET

Removal

1. Remove the fuel inlet line and vacuum line.
2. Place a suitable container under the fuel bowl and drain the bowl by loosening one of the lower fuel bowl retaining screws. Remove the container.
3. Remove the four fuel bowl retaining screws.
4. Remove the fuel bowl, gasket and baffle, and metering block and gasket. Discard the gaskets.

Installation

1. If the fuel bowl or metering block is being replaced, transfer the parts.
2. Position the metering block gasket on the dowels on the back of the metering block.
3. Lay the metering block in place on the main body.
4. Position the baffle and fuel bowl gasket on the metering block.
5. Place the fuel bowl on the metering block. Use new compression gaskets on the bowl retaining screws; then install and tighten the screws.

POWER VALVE AND GASKET

Removal

1. Remove the fuel bowl and metering block.
2. Using a socket wrench, remove the power valve and gasket.
3. Discard the gasket.

Installation

1. Place a new gasket on the specified power valve.
2. Using a socket wrench, install the power valve and gasket.
3. Install the fuel bowl and metering block.

MAIN JET

1. Remove the fuel bowl and metering block.
2. Use a jet wrench to remove and install the jets.
3. Install the fuel bowl and metering block.

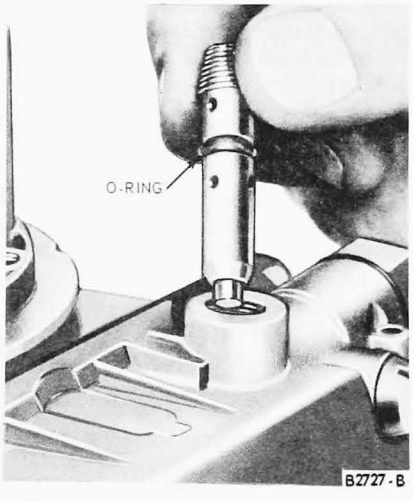

FIG. 9 Removing Fuel Inlet Needle and Seat

ACCELERATING PUMP DIAPHRAGM

Removal

1. Remove the fuel bowl and metering block.
2. Remove the accelerating pump cover, diaphragm and spring.

Installation

1. Place the spring and diaphragm in the accelerating pump chamber. The diaphragm must be positioned so that the diaphragm disc protrudes from the fuel bowl.
2. Install the cover screws finger tight.
3. Make sure the diaphragm is centered, compress the diaphragm with the pump operating lever and tighten the cover screws.

FLOAT

1. Using needle nose pliers, remove the float retainer.
2. Slide the float off the shaft.
3. Remove the spring from the float.

Installation

1. Install the float spring on the float.
2. Slide the float on the shaft.
3. Install the float retainer.

FUEL INLET NEEDLE AND SEAT

Removal

The fuel inlet needle and seat assembly can be replaced without removing the fuel bowl.

1. Remove the air cleaner.
2. Remove the fuel level adjustment lock screw and gasket. Turn the adjusting nut out and remove the adjusting nut and gasket. Remove the fuel inlet needle and seat assembly (Fig. 9). **Do not disassemble the fuel inlet needle and seat assembly. They are matched parts and are serviced as an assembly.**

Installation

1. Position the fuel inlet needle and seat assembly in the fuel bowl.
2. Position the adjusting nut gasket and nut on the fuel inlet needle and seat assembly. Align the flat on the ID of the nut with the flat on the OD of the fuel inlet needle and seat assembly.
3. Install the fuel level adjustment lock screw and gasket.
4. Adjust the fuel level.

DISASSEMBLY AND ASSEMBLY

DISASSEMBLY

To facilitate working on the carburetor and to prevent damage to the throttle plates, install bolts about 2 1/4 inches long of the correct diameter through the carburetor retaining bolt holes with a nut above and below the flange (or install carburetor legs).

Use a separate container for the component parts of the various assemblies to facilitate cleaning, inspection, and assembly.

The following is a step-by-step sequence of operations for completely overhauling the carburetor; however, certain components of the carburetor may be serviced without disassembling the entire unit. For a complete carburetor overhaul, follow all the steps. To partially overhaul the carburetor or to install a new gasket kit, follow only the applicable steps.

FUEL BOWLS AND METERING BLOCKS

Refer to Fig. 10 for the correct location of the fuel bowl parts.

1. Remove the primary fuel bowl and gasket, and the metering block and gasket. Discard the gaskets.
2. Remove the fuel transfer line and discard the O-ring seals.
3. Remove the balance tube, washer, and O-ring seal. Discard the O-ring seal.
4. Using a socket wrench, remove the power valve and gasket (Fig. 11).
5. Using a jet wrench, remove the main jets (Fig. 12).

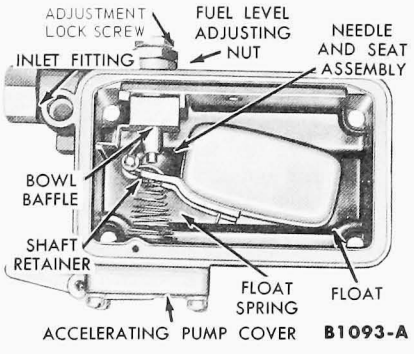

FIG. 10 Fuel Bowl—401, 477 and 534 CID Engines

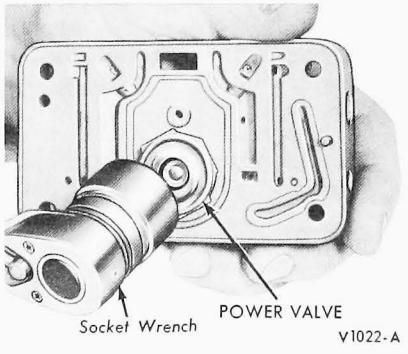

FIG. 11 Removing or Installing Power Valve

6. Remove the fuel level adjustment lock screw and gasket. Turn the adjusting nut counterclockwise and remove the locknut and gasket, and the fuel inlet needle and seat assembly. **Do not disassemble the fuel inlet needle and seat. They are matched and are replaced as an assembly.**
7. Using needle nose pliers (Fig. 13), remove the float retainer. Slide the float off the shaft. Remove the

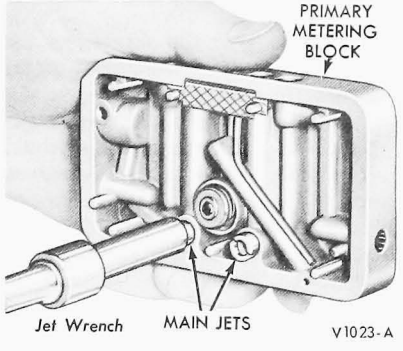

FIG. 12 Removing or Installing Main Jet

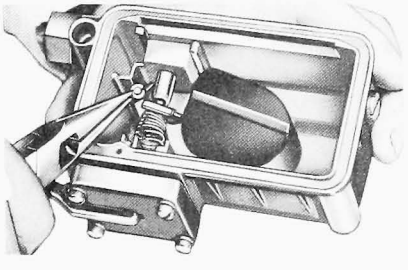

FIG. 13 Removing Float Shaft Retainer

spring from the float.
8. Remove the baffle plate from the fuel bowl.
9. Remove the fuel level sight plug and gasket.
10. Remove the fuel inlet fitting, gasket, and filter screen.
11. Invert the fuel bowl and remove the accelerating pump cover, diaphragm and spring. **The accelerating pump inlet ball check is not removable.**
12. Remove the secondary fuel bowl and gasket and the metering block and gasket. Discard the gaskets. Remove the balance tube washer and O-ring seal. Discard the O-ring seal.
13. Remove the following parts from the secondary metering block:

Do not remove the idle mixture adjusting limiters or adjusting screws.

14. Disassemble the secondary fuel bowl by following steps 6, 7, 8 and 9.

MAIN BODY

1. Remove the air cleaner anchor screw.
2. **On the 391 CID engine, remove the choke control lever, governor seal wire and the governor housing cover. Remove the nut and washer retaining the governor lever to the throttle shaft, then remove the governor housing. Remove the secondary diaphragm link retainer.**

On 401, 477 and 534 CID engines, remove the secondary diaphragm link retainer. Remove the fast idle cam housing, attaching screws and lockwashers, then remove the fast idle cam housing.

Remove the nut securing the choke swivel to the fast idle cam housing, then remove the choke swivel and fast idle cam assembly. Remove the plunger and spring from the fast idle cam.

3. Invert the carburetor and remove the throttle body to main body screws and lockwashers. Lift off the main body and remove the main body gasket. Discard the gasket.
4. Remove the retainer securing the choke rod to the choke rod lever and bushing assembly, then remove the lever retainer and remove the lever and lever spring.
5. Remove the choke rod retainer from the choke plate shaft lever. Remove the choke rod, washers, and seal from the main body.
6. Remove the choke plate assembly.
7. Slide the choke plate shaft out of the main body.
8. **On 401, 477 and 534 CID engines,** remove the retainers, spring seats, and springs from the poppet valve on the front of the main body. Use throttle body. Referring to the lines **caution to avoid losing the spring as they are under compression.** Remove the pins and poppet valve.
9. Remove the secondary diaphragm housing and gasket from the main body. The housing must be removed before the cover can be removed. Remove the diaphragm housing cover, then remove the spring and diaphragm, and the secondary vacuum ball check. Remove the distributor vacuum fitting.
10. Remove the accelerating pump discharge nozzle screw, then lift the pump discharge nozzle and gasket out of the main body. Invert the main body and let the discharge needle fall into the hand.

GOVERNOR HOUSING—391 CID ENGINE

1. Mark the governor spring pin hole to facilitate assembly. Remove the spring and pin.
2. Remove the diaphragm rod retainer and governor lever.
3. Remove the governor line fitting. **Make a note of the governor by-pass jet numbers and positions. Remove the by-pass jets, the diaphragm cover, and the diaphragm.**
4. Remove the fast idle cam shaft retainer and slide the fast idle cam and shaft out of the housing.
5. Remove the cam plunger, spring, and fast idle pin.

THROTTLE BODY—391 CID ENGINE

1. Remove the accelerating pump lever and the throttle operating shaft housing.
2. If the primary throttle shaft is to be removed, drive out the primary throttle shaft pin (Fig. 14). Remove the secondary throttle plates operating lever.
3. If it is necessary to remove the throttle plates, lightly scribe the primary and secondary throttle plates along the throttle shafts and mark each plate and its corresponding bore with a number or letter for proper installation (Fig. 15). Remove the throttle plates.
4. Remove the throttle connecting rod and the spacer (from the primary throttle lever). Remove the throttle operating housing plate.
5. If the throttle shafts are to be replaced, remove the throttle plates by following step 3 and slide the primary and secondary throttle shafts and bushings out of the throttle body.

THROTTLE BODY—401, 477 AND 534 CID ENGINES

1. Remove the accelerating pump lever and the throttle operating shaft housing.
2. Drive out the governor lever retaining pin, then loosen the governor lever screw and remove the lever. Remove the fast idle cam lever and the secondary diaphragm lever.
3. If it is necessary to remove the throttle plates, lightly scribe the primary and secondary throttle plates along the throttle shafts and mark each plate and its corresponding bore with a number or letter for proper installation (Fig. 15). Remove the throttle plates.
4. Remove the throttle connecting rod retainers, washer (from the secondary throttle lever) and the connecting rod. Slide the primary and secondary throttle shafts and bushings out of the throttle body. Remove the throttle operating housing plate.

THROTTLE OPERATING HOUSING—391 CID ENGINE

1. Remove the idle (hot engine) speed adjustment screw and spring.
2. Remove the throttle shaft driver retaining screw from inside the housing, then remove the driver.

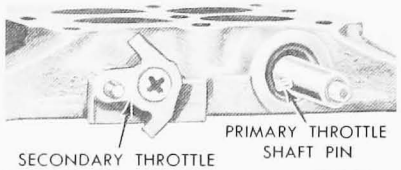

FIG. 14 Primary Throttle Shaft Pin

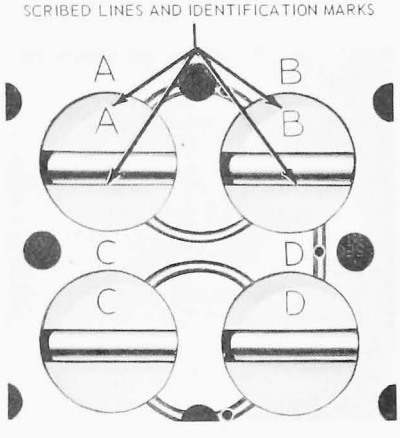

FIG. 15 Removing Throttle Plate

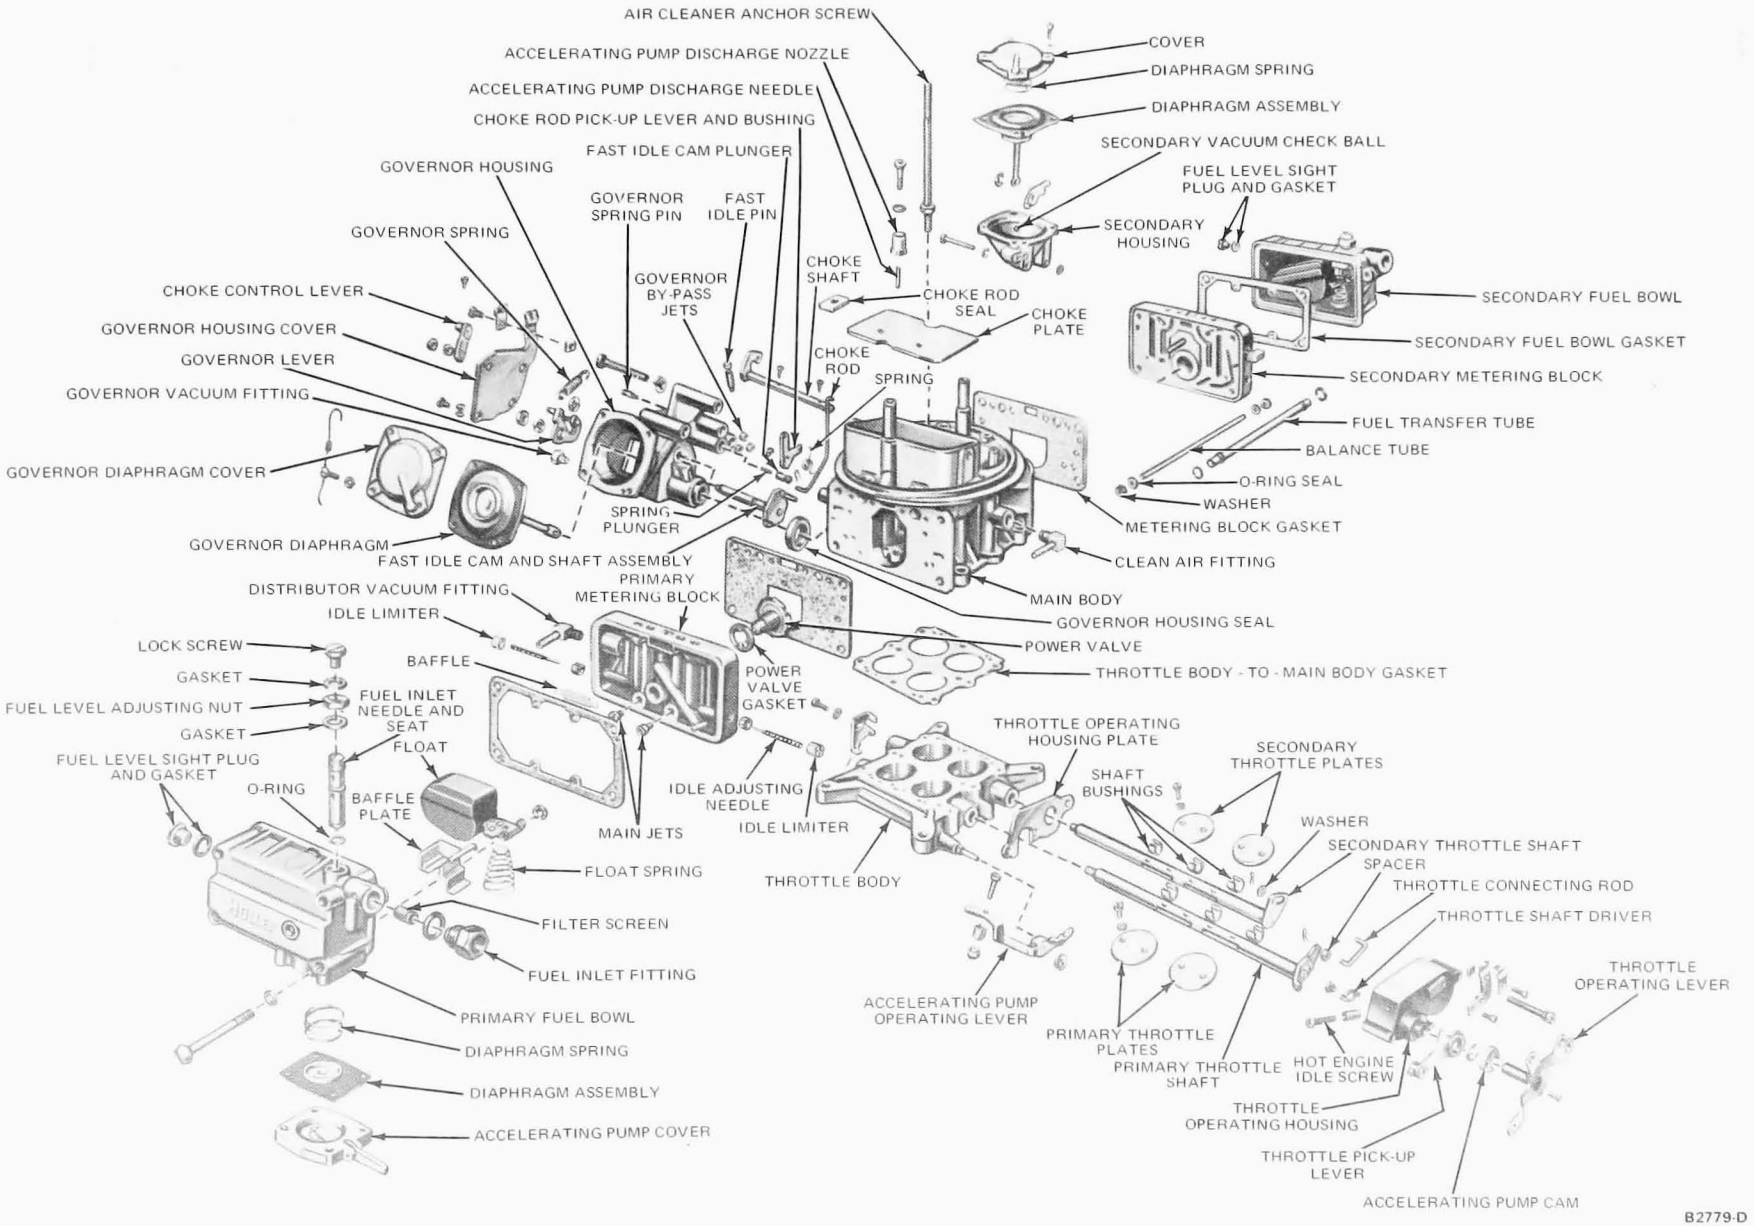

FIG. 16 Carburetor Assembly—Holley 4-V for 391 CID Engine

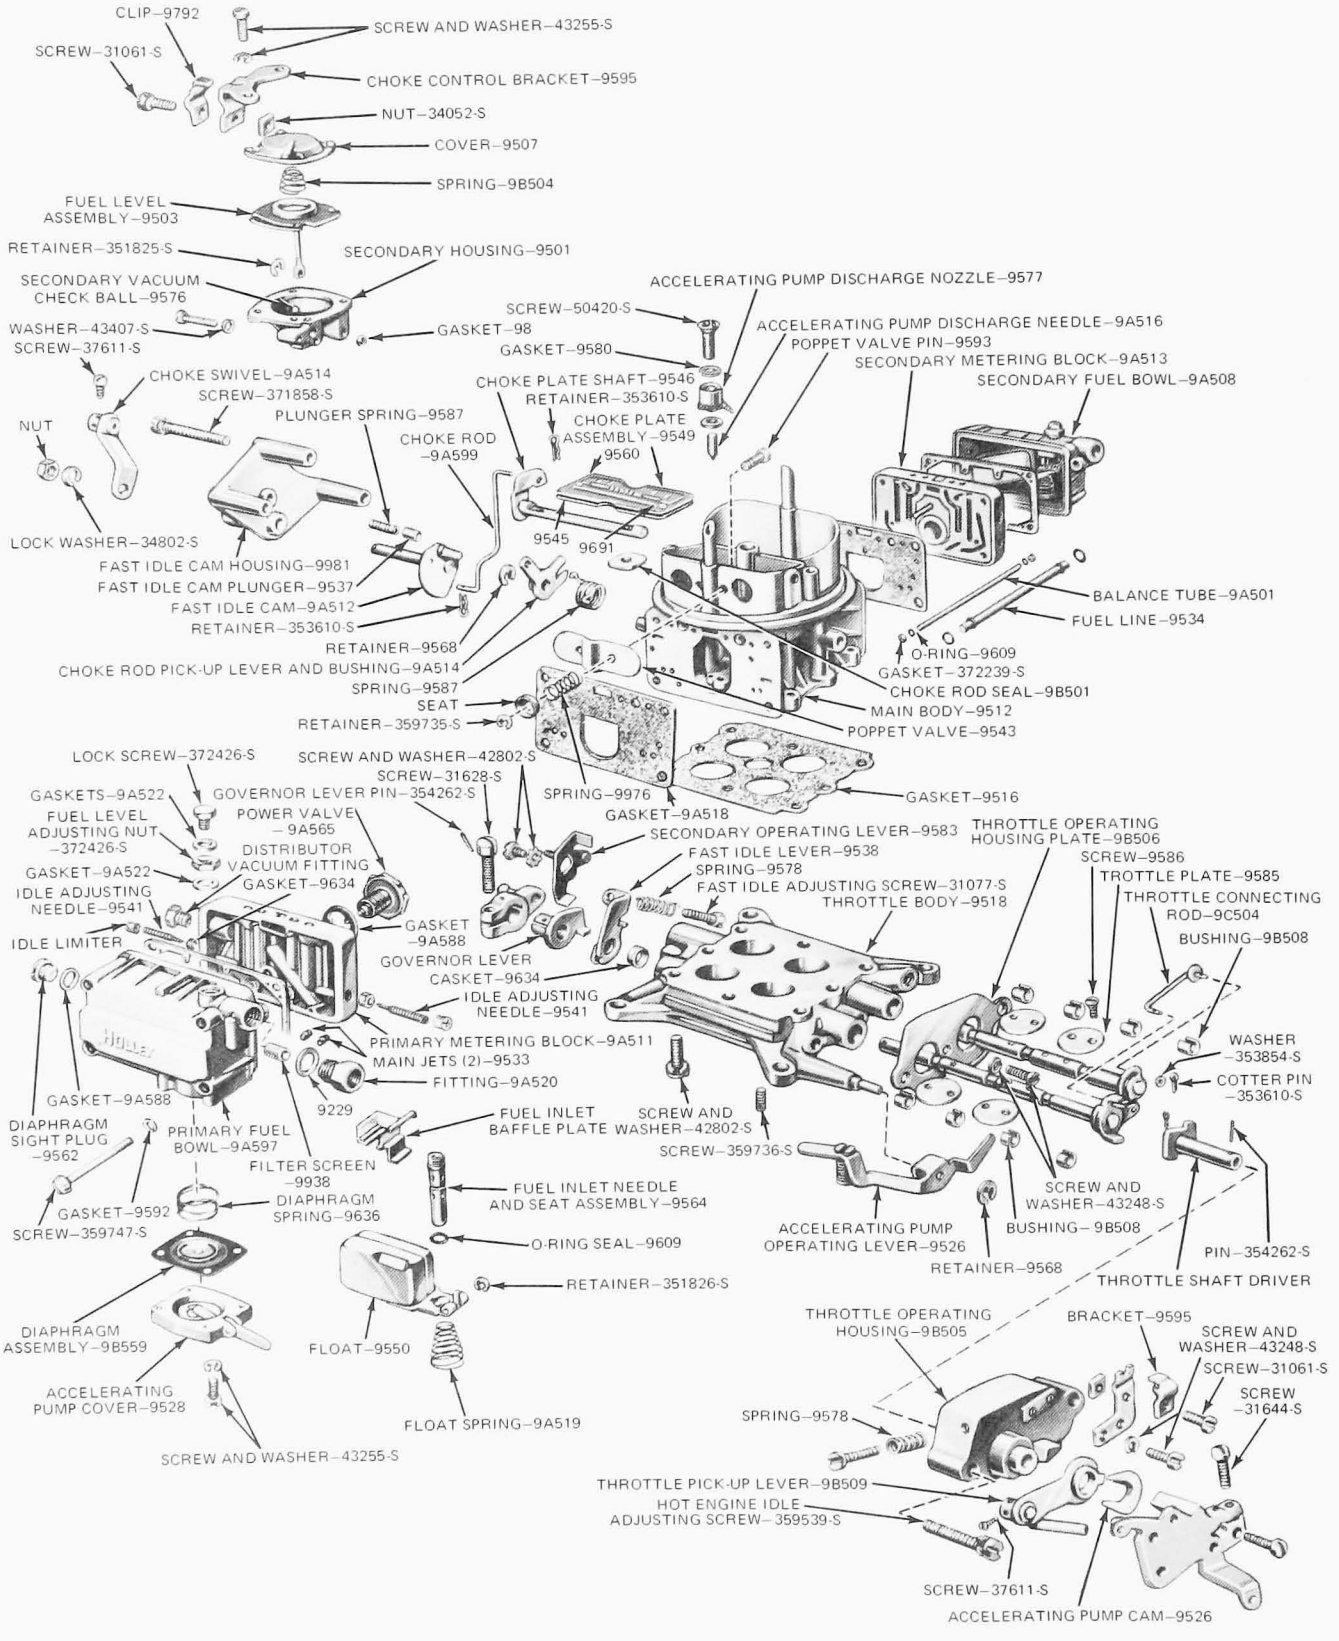

FIG. 17 Carburetor Assembly—Holley 4-V for 401, 477 and 534 CID Engines

3. Slide the throttle operating lever and shaft assembly out of the housing.
4. Remove the accelerating pump cam from the throttle operating lever.
5. Remove the throttle cable bracket.

THROTTLE OPERATING HOUSING—401, 477 AND 534 CID ENGINES

1. Remove the hot engine idle screw and spring, and the pick-up lever bracket.
2. Remove the retaining pin from the throttle operating lever, then loosen the lever screw and remove the lever.

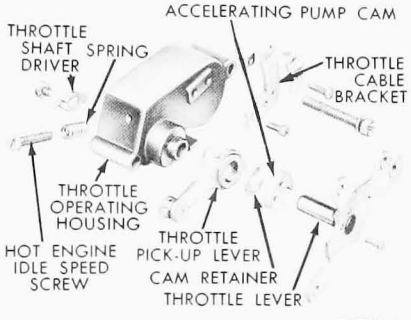

FIG. 18 Throttle Operating Housing

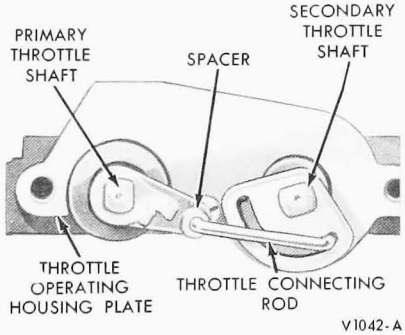

FIG. 19 Installing Throttle Connecting Rod— 391 CID Engine

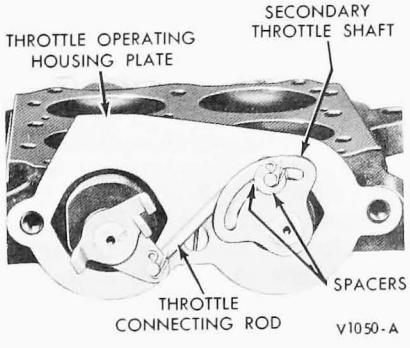

FIG. 20 Installing Throttle Connecting Rod—401, 477 and 534 CID Engines

3. Slide the throttle shaft driver and shaft out of the housing. Remove the pick-up lever and swivel assembly.
4. Remove the accelerating pump cam from the throttle operating lever.

Carburetor cleaning and inspection are covered in Part 24-01.

ASSEMBLY

Make sure all holes in the new gaskets have been properly punched and that no foreign material has adhered to the gaskets. Make sure the accelerating pump diaphragm and the secondary operating diaphragm are not cut or torn.

Disassembled views of the carburetors are shown in Figs. 16 and 17.

THROTTLE OPERATING HOUSING—391 CID ENGINE

Refer to Fig. 18 for the correct location of the parts.

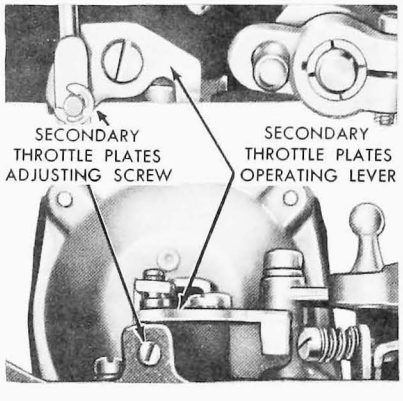

FIG. 21 Secondary Throttle Plate Adjustment

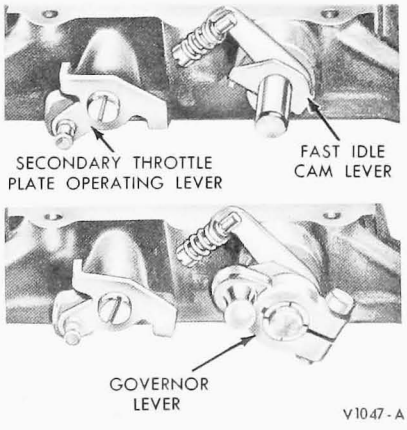

FIG. 22 Fast Idle Cam Lever and Governor

1. Install the idle (hot engine) speed adjustment screw and spring. Turn the screw in until spring tension is felt.
2. Install the throttle cable bracket.
3. Install the accelerating pump cam on the throttle operating lever.
4. Position the throttle pick-up lever and swivel assembly on the throttle operating housing bushing with the throttle cable clamp on the inside.
5. Slide the throttle operating lever into the housing, then install the driver in the end of the throttle operating lever shaft so that the throttle operating lever can be rotated from the full open position to the full closed position. If the throttle lever cannot be rotated from the open to the close position, remove the drive and reposition it.

THROTTLE OPERATING HOUSING—401, 477 AND 534 ENGINES

1. Install the hot engine idle screw and spring. Turn the screw in until spring tension is felt. Install the pick-up lever bracket.
2. Install the accelerating pump cam on the throttle operating lever.
3. Slide the throttle shaft driver and shaft into the throttle operating housing.
4. Position the throttle pick-up lever and swivel assembly on the throttle operating housing bushing with the tang on the lever facing out.
5. Slide the throttle operating lever on the shaft with the retaining pin hole in the lever and shaft aligned. Tighten the lever tension screw. Be sure the throttle lever can be rotated from the full open to the full closed position, then install the retaining pin. If the throttle lever can not be rotated from the open to the closed position, it will be necessary to remove the throttle shaft driver and reposition it.

THROTTLE BODY

1. If the throttle plates were removed, position the bushings on the throttle shafts and slide them into the scribed on the throttle plates, install the plates in their proper location with the screws snug, but not tight. Close the throttle plates and hold the throttle body up to the light. Little or no light should show between the throttle plates and the throttle bores. If the throttle plates are properly installed and there is no binding when the throttle shafts are rotated, tighten and stake the screws.

2. Install the throttle operating housing plate and the throttle connecting rod. Be sure the throttle connecting rod is installed as shown in Figs. 19 and 20. Install the accelerating pump lever, and the secondary throttle plate operating lever.
3. Hold the secondary throttle plates closed. Turn the secondary throttle plate stop screw (Fig. 21) until it just touches the tab on the secondary operating lever, then turn it in 1/4 turn.
4. **On 391 CID engines,** invert the throttle body and open the primary throttle plates, then install the primary throttle shaft pin so that it protrudes approximately 3/16 inch from the shaft.

On 401, 477 and 534 CID engines, position the fast idle cam lever on the primary throttle shaft. Position the governor lever on the primary throttle shaft with the retaining pin holes in the lever and shaft aligned. Tighten the lever tension screw, then install the retaining pin (Fig. 22).

5. Open the primary throttle plates and install the throttle operating housing on the throttle body. **A correctly installed throttle lever and retainer lever will close the throttle plates, but will not open them.**

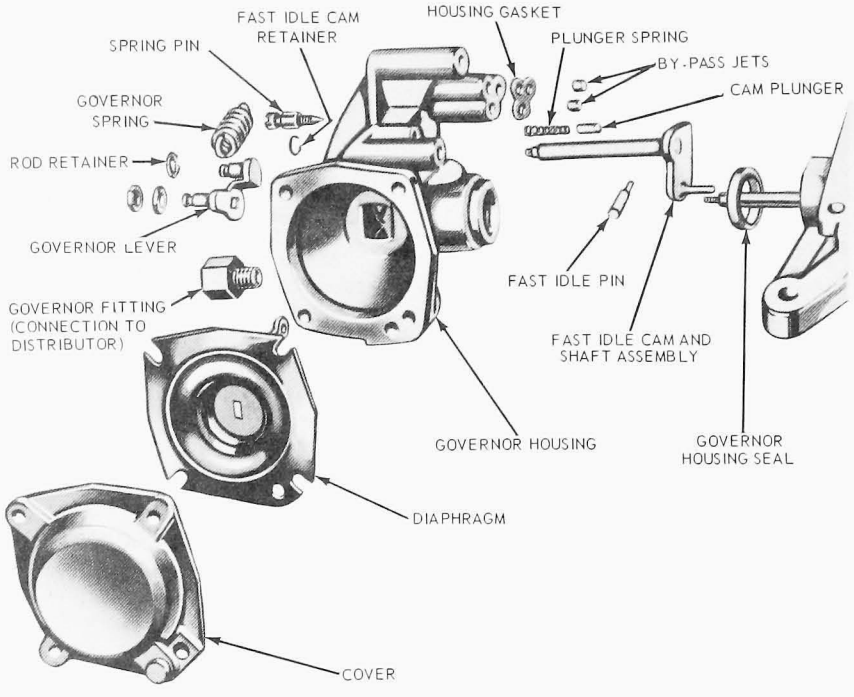

FIG. 23 Governor Housing

GOVERNOR HOUSING—391 CID ENGINE

Refer to Fig. 23 for the correct location of the parts.

1. Place the fast idle pin in position in the governor housing.
2. Insert the fast idle cam plunger spring in the plunger and install the assembly in the governor housing.
3. Slide the fast idle cam assembly into position and install the retainer.
4. Install the governor by-pass jets and the governor line fitting.
5. Install the governor spring pin in the same marked hole from which it was removed.
6. Position the governor diaphragm in the governor housing. Position the diaphragm properly to avoid damage by the screws. Install the cover with the screws finger tight. Pull the diaphragm rod as far as it will go and tighten the cover screws. Install new safety wire and a seal.
7. Place the governor lever in the housing and insert the diaphragm rod on the smallest stud of the lever. Install the rod retainer.
8. Install the governor spring on the spring pin and governor lever stud. The governor housing is installed after the throttle body is assembled in the main body.

MAIN BODY

1. Drop the accelerating pump discharge needle into its well (Fig. 24).
2. Seat the needle with a brass drift and a light hammer. Make sure the needle is free.
3. Position the accelerating pump discharge nozzle gasket and nozzle in the main body, then install the attaching screw.
4. Drop the secondary vacuum ball check in the vacuum passage in the secondary diaphragm housing (Fig. 25).
5. Position the secondary diaphragm in the housing and place the spring on the diaphragm disc. Position the diaphragm properly to avoid damage by the screws. Install the cover with the screws finger-tight. Compress the diaphragm spring by pushing the diaphragm rod inward as far as it will go and tighten the cover screws. **The diaphragm housing must be removed from the main body to install the cover.**
6. Place the gasket on the secondary vacuum passage opening on the main body. Lay the diaphragm housing in position on the main body and install the lockwashers and attaching screws.

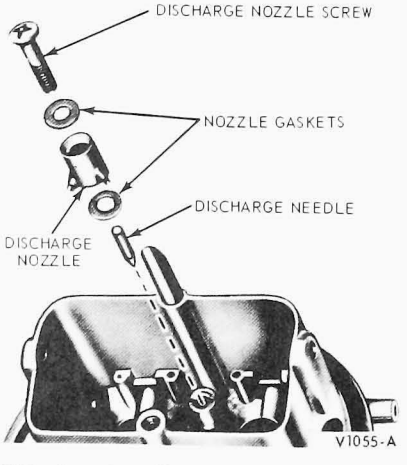

FIG. 24 Installing Accelerating Pump Discharge Needle

7. **On 401, 477 and 534 CID engines,** place the air horn poppet valve in position on the main body. From inside the primary air horn, insert the attaching screws through the main body and poppet valve. Install the springs, spring seats and retainers on the attaching screws.
8. Position the choke plate shaft in the air horn.

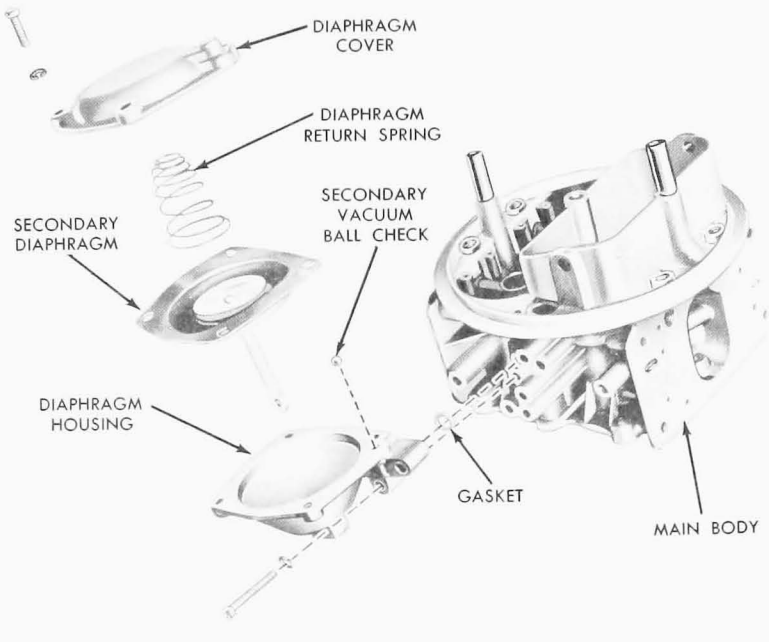

FIG. 25 Secondary Diaphragm Assembly

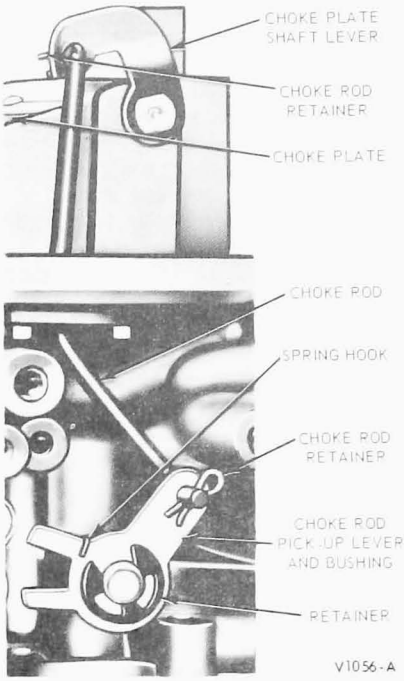

FIG. 27 Installing Choke Rod—401, 477 and 534 Engine

9. Position the choke plate assembly on the choke plate shaft, then install the attaching screws and the self-locking jam nuts (Fig. 26).
10. Install the rod seal in the retaining groove located on the underside of the carburetor air cleaner flange.
11. Slide the choke rod through the opening in the main body and secure it to the choke plate shaft lever with a pin retainer.
12. Place the choke rod lever spring on the lever with the end of the spring with the largest hook on the lever (Fig. 27).
13. Place the choke rod lever and spring assembly in position on the main body with the other end of the spring fitting in the groove in the main body.
14. Secure the choke rod to the lever with a pin retainer. Install the choke lever retainer.
15. Insert the fast idle cam plunger spring in the plunger and install the assembly in the plunger bore in the fast idle cam housing.
16. Install the fast idle cam in the fast idle cam housing and install the

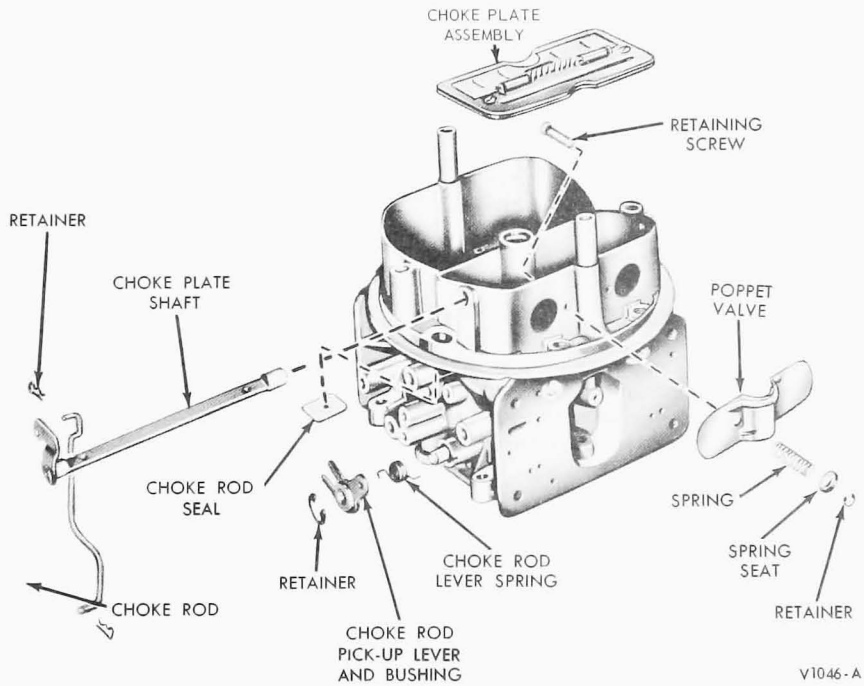

FIG. 26 Choke Plate and Poppet Valve Assembly—401, 477 and 534 CID Engines

choke swivel, lockwashers, and attaching nut on the end of the fast idle cam shaft.

17. Position the fast idle cam housing on the main body so that the pin on the fast idle cam is between the two tangs on the choke rod lever. Install the housing attaching screws.
18. Invert the main body and position the throttle body gasket on the main body. Slide the secondary diaphragm rod onto the operating lever as the throttle body is placed into position. Install the diaphragm operating rod retainer.
19. Install the throttle body to main body screws and lockwashers.
20. Install the air cleaner anchor stud.

FUEL BOWLS AND METERING BLOCKS

Refer to Fig. 28 for the correct location of the fuel bowl parts. The primary and secondary fuel bowls and metering blocks are installed on the main body in the same sequence (Fig. 29).

1. Place the accelerating pump diaphragm spring and diaphragm in the accelerating pump chamber of the primary fuel bowl. The diaphragm must be positioned so that the large end of the lever disc will be against the operating lever. Install the cover with the screws finger-tight. Make sure the diaphragm is centered, then compress the diaphragm with the pump operating lever and tighten the cover screws.
2. Install the fuel lever sight plug and gasket.
3. Slide the baffle plate on the ridges in the fuel bowl.
4. Install the float spring on the float and slide the float on the shaft. Be sure the float spring is between the ridges on the boss of the floor of the fuel bowl. Using needle nose pliers, install the float retainer.
5. Apply Vaseline to a new O-ring seal and slide it on the fuel inlet needle and seat assembly.
6. Position the fuel inlet needle and seat assembly in the fuel bowl through the top of the bowl. Position the adjusting nut gasket and nut on the fuel inlet needle and seat assembly. Align the flat on the ID of the nut with the flat on the OD of the fuel inlet needle and seat assembly. Install the fuel level adjustment lock screw and gasket.
7. Perform a dry float adjustment (under Adjustments of this Part).
8. Using a socket wrench, install the power valve and a new gasket in the metering block. **Be sure to install the correct power valve. Refer to specifications for the correct identification number. The number is stamped on a flat on the base of the valve.** Using a jet wrench, install the main jets in the metering block.
9. Apply Vaseline to a new O-ring seal and slide it on one end of the balance tube, then slide the washer on the same end of the balance tube. Slide the balance tube through the hole on the primary side of the main body and through the hole in the secondary side of the main body (Fig. 30). Position the balance tube so that the tube protrudes equally at each end. Push the O-ring seal and washer into the recess in the main body (Fig. 30).
10. Position the primary metering block

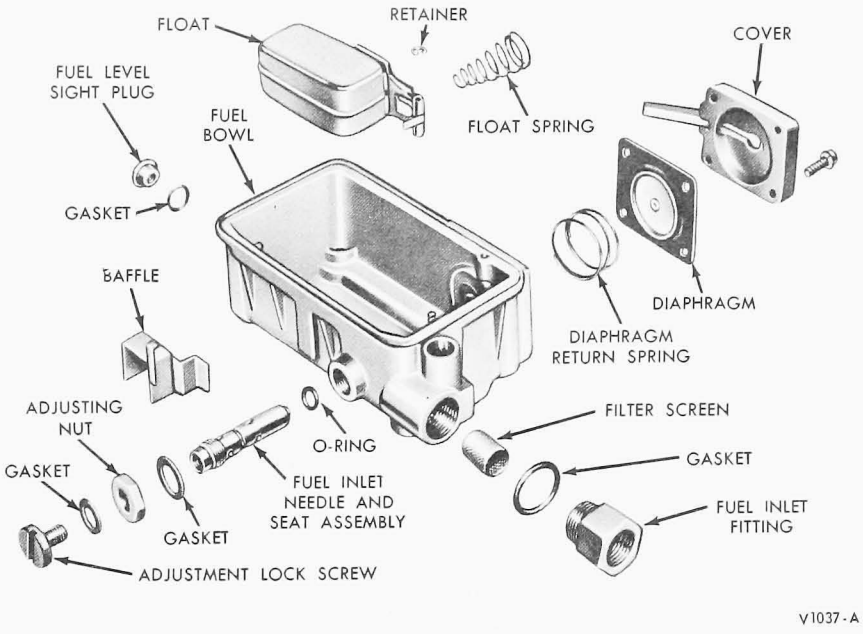

FIG. 28 Primary Fuel Bowl Assembly

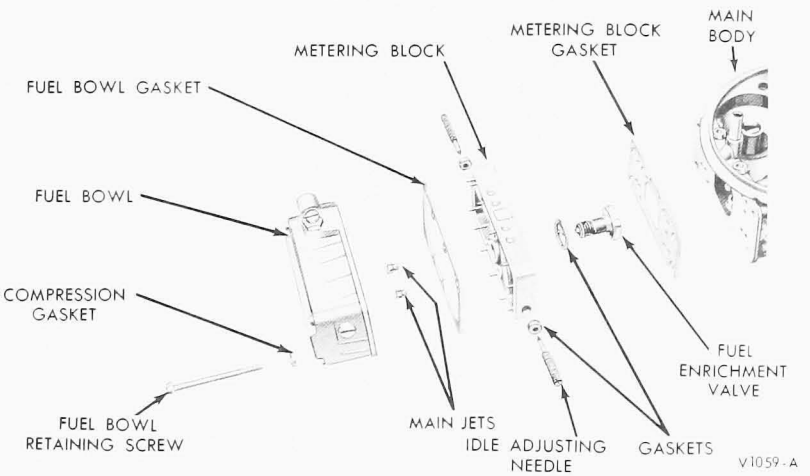

FIG. 29 Secondary Fuel Bowl and Metering Block Assembly

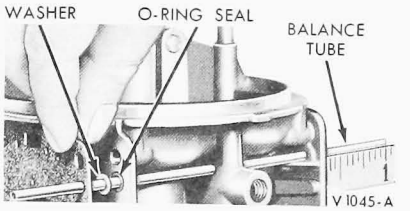

FIG. 30 Installing Balance Tube

gasket on the dowels on the back of the metering block. Lay the metering block in position on the main body. Position the fuel bowl gasket in the metering block. Place the retaining screws with new compression gaskets in the fuel bowl. Lay the bowl in place on the metering block and tighten the attaching screws.

11. Apply Vaseline to the fuel line O-ring seal and place the seal against the flange on one end of the fuel line and install this end of the line in the primary fuel bowl.
12. Assemble the secondary fuel bowl by following steps 2, 3, 4, 5, 6 and 7.
13. Install the following parts in the secondary metering block:

Using a jet wrench, install the secondary main jets.

14. Apply Vaseline to a new O-ring seal and slide it on the end of the balance tube protruding from the secondary side of the main body. Press the seal into the recess in the main body. Slide the washer on the tube and press it into the recess in the main body so that it covers the O-ring seal.
15. Install the metering block, fuel bowl, and gaskets by following step 10.

PART 24-30 Fuel Pump—Mechanical

This Information Applies To All Engines Except 401, 477 and 534 CID

COMPONENT INDEX	Page	COMPONENT INDEX	Page
CAPACITY TEST	30-02	FUEL PUMP ASSEMBLY	
CARTER FUEL PUMP (EXCEPT PERMANENTLY SEALED TYPE)		Description	30-01
		Installation	30-03
Assembly	30-03	Removal	30-03
Disassembly	30-03		
CARTER PERMANENTLY SEALED FUEL PUMPS		PRESSURE TESTS	30-02
Assembly	30-03	SPECIFICATIONS	30-04
Disassembly	30-03		

DESCRIPTION

Single-action mechanical fuel pumps are standard equipment for all engines except the 401, 477 and 534 V-8's.

The mechanical fuel pumps on 6-cylinder engines are mounted on the lower, left-center of the engine cylinder block.

On all V-8 engines, the mechanical fuel pumps are mounted on the left side of the cylinder front cover.

A Carter design fuel pump (Fig. 1) with a long-life, disposable type integrally mounted fuel filter on the pump body is used on the 300 HD Six, and the 330, 361 and 391 V-8 engines.

Carter permanently sealed design fuel pumps with integral fuel filters are used on the 240, 300 Six and the 360 and 390 V-8 engines (Fig. 2) for light and medium duty F, B, LN and P-Series trucks. The Bronco and Econoline engines also use permanently-sealed fuel pumps (Figs. 3 and 4), but with separate in-line fuel filters.

The fuel pumps are mechanically actuated by means of the fuel pump rocker arm and an eccentric on the camshaft.

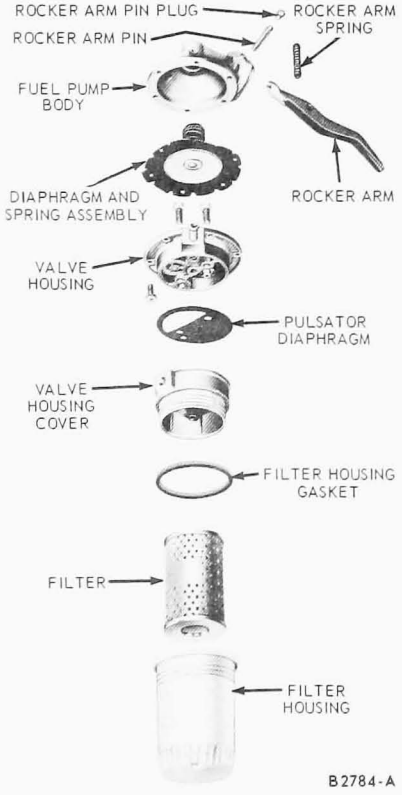

FIG. 1 Carter Fuel Pump — 300 HD Six, and 330, 361 and 391 V-8 Engines

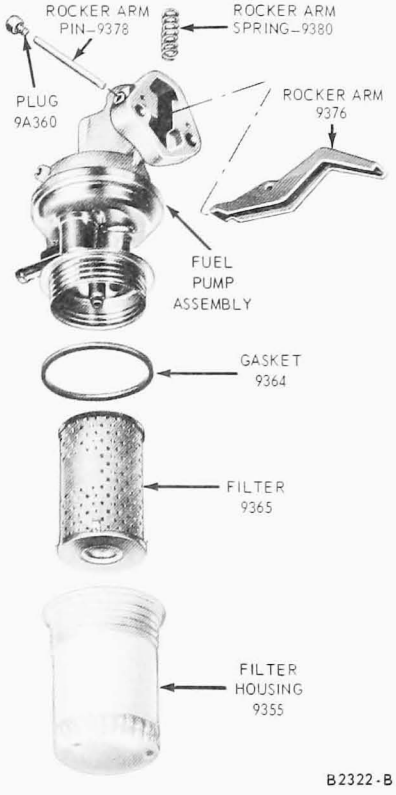

FIG. 2 Carter Sealed Design Fuel Pump — 240, 300 Six and 360 and 390 V-8 Engines

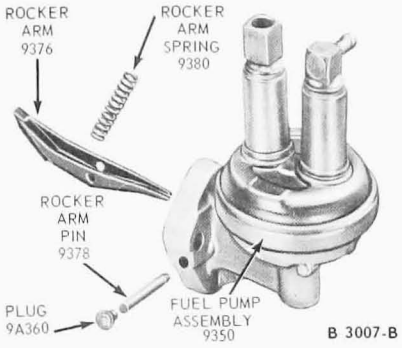

FIG. 3 Carter Permanently-Sealed Fuel Pump for Bronco and Econoline Six

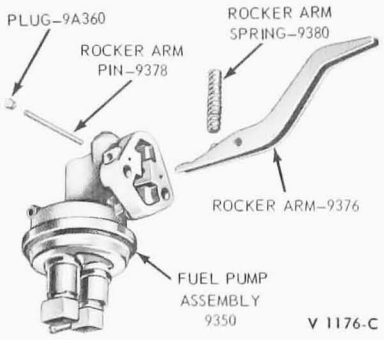

FIG. 4 Carter Permanently Sealed Fuel Pump for Bronco and Econoline V-8 Engines

TESTING

To determine that the fuel pump is in satisfactory operating condition, tests for both fuel pump pressure and fuel pump capacity (volume) should be performed.

The tests are performed with the fuel pump installed on the engine and the engine at normal operating temperature at idle speed.

Before the tests, make sure the replaceable fuel filter has been changed within the recommended maintenance mileage interval. When in doubt, install a new filter.

PRESSURE TESTS

Refer to the fuel pump specification in this Part, and note the fuel pump pressure and capacity (volume) design tolerances.

1. Remove the air cleaner assembly. Disconnect the fuel inlet line or the fuel filter at the carburetor. **Use care to prevent combustion due to fuel spillage.**
2. Connect a pressure gauge, a restrictor and a flexible hose (Fig. 5) between the fuel filter and the carburetor.
3. Position the flexible hose and the restrictor so the fuel can be discharged into a suitable, graduated container (Fig. 5).
4. Before taking a pressure reading operate the engine at the specified idle rpm and vent the system into the container by opening the hose restrictor momentarily.
5. Close the hose restrictor, allow the pressure to stabilize, and note the reading. Refer to the Specifications Section in this Part.

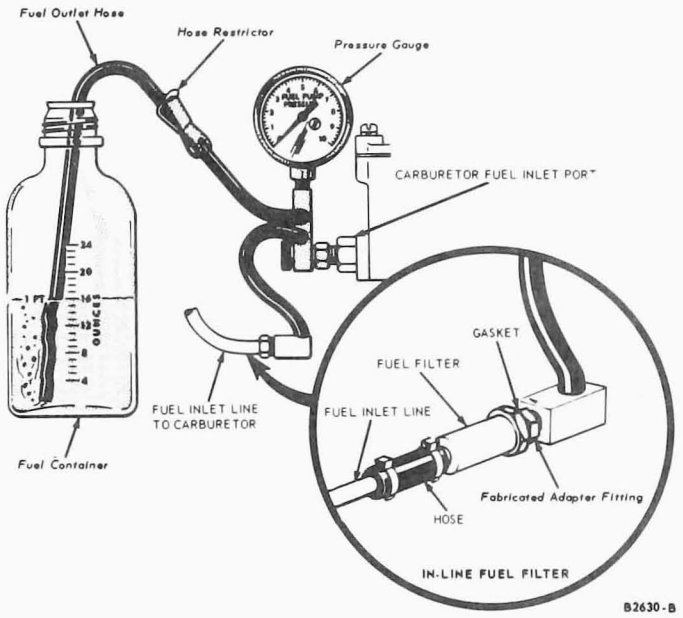

FIG. 5 Typical Fuel Pump Pressure and Capacity Test Equipment

If the pump pressure is not within specifications, and the fuel lines and filter are in satisfactory condition, the pump is defective and should be replaced.

If the pump pressure is within specifications, perform the tests for fuel capacity (volume).

CAPACITY (VOLUME) TEST

With the fuel pump pressure within specifications, test the capacity (volume) as follows:

1. Operate the engine at the specified idle rpm.
2. Open the hose restrictor and expel the fuel into the container (Fig. 5), while observing the time required to expel one pint. Close the restrictor. One pint or more of fuel should be expelled within the specified time limit.

If the pump volume is below specifications, repeat the test using an auxiliary fuel supply and a new fuel filter. If the pump volume meets specifications while using the auxiliary fuel supply, check for a restriction in the fuel supply from the tank and for the tank not venting properly.

REMOVAL AND INSTALLATION

FUEL PUMP ASSEMBLY

REMOVAL

1. Disconnect the inlet and outlet lines at the fuel pump.
2. Remove the pump attaching screws, then remove the pump and the gasket. Discard the gasket.

INSTALLATION

1. Remove all the gasket material from the mounting pad and pump flange. Apply oil-resistant sealer to both sides of a new gasket and to the threads on the attaching bolts.
2. Position the new gasket on the pump flange and hold the pump in position against the mounting pad. Make sure the rocker arm is riding on the camshaft eccentric. (Turn engine over until the fuel pump eccentric is on the low side of the stroke.)
3. Press the pump tight against the pad, install the attaching screws and alternately torque them to specifications.
4. Connect the fuel inlet and outlet lines.
5. Operate the engine and check for leaks.

DISASSEMBLY AND ASSEMBLY

CARTER FUEL PUMP (EXCEPT PERMANENTLY SEALED TYPE)

DISASSEMBLY

1. Remove the filter housing, gasket and filter element. Discard the filter element.
2. Scribe marks on the fuel pump body, valve housing and valve housing cover so that these parts can be assembled in their original position.
3. Remove the valve housing assembly. Separate the valve housing from the cover and note the position of the pulsator diaphragm so that it can be assembled in its proper position. **Do not remove the fuel valves from the valve housing. The valve housing is replaced as an assembly.**
4. Scrape away the staking mark and remove the rocker arm pin seal plug as shown in Fig. 6.
5. Press the fuel pump diaphragm into the fuel pump body to release the tension on the rocker arm and allow the rocker arm pin to fall out. If the pin does not come out freely, use needle nose pliers (Fig. 7).
6. Press the diaphragm into the fuel pump body and pull the rocker arm out to unhook the rod from the rocker arm link (Fig. 8). Remove the rocker arm spring.
7. Remove the fuel pump diaphragm assembly. Do not disassemble as the diaphragm and spring are serviced as an assembly only.

ASSEMBLY

1. Insert the rocker arm spring into the fuel pump rocker arm cavity. Insert the rocker arm into the cavity.
2. Position the fuel pump diaphragm assembly into the pump body, then apply pressure on the diaphragm spring so that the rocker arm can be hooked on the rod.
3. Align the rocker arm pin holes by applying slight pressure on the diaphragm spring, then install the rocker arm pin (Fig. 7). **Make certain the rocker arm spring is properly positioned on the spring locater on the rocker arm.**
4. Install a new rocker arm pin seal plug. Stake the plug in position.
5. Place a new pulsator diaphragm on the valve housing in the position previously noted during disassembly (opening in the diaphragm over the fuel inlet chamber as shown in Fig. 9). Position the cover on the valve housing, aligning the scribe lines on the cover with the line on the valve housing. Be sure the pulsator diaphragm extends evenly around the edge of the cover. Install and tighten the two attaching screws and lock washers inside the valve housing.
6. Align the scribe line on the valve housing and the line on the fuel pump body. Hold the valve housing assembly tight against the fuel pump body and install the six screws and lock washers. Be sure the fuel pump diaphragm extends evenly around the edge of the valve housing before tightening the attaching screws.
7. Install the fuel filter assembly. Refer to Fuel Filter Replacement (Part 24-51) for the proper procedure.

CARTER PERMANENTLY SEALED FUEL PUMPS

DISASSEMBLY

The fuel pump assembly is shown in Figs. 2, 3 and 4.

1. Remove the filter housing, gasket and filter element. Discard the gasket and the filter element.
2. Scrape away the staking mark and remove the rocker arm pin seal plug as shown in Fig. 6.
3. Release the tension on the rocker arm by pressing the arm downward against the diaphragm and against rocker arm spring pressure and allow the rocker arm pin to fall out. If the pin does not come out freely, tap the fuel pump assembly lightly on the bench until the pin sticks out of the bore and remove the pin with pliers. Remove the rocker arm and spring.

Clean and inspect the fuel pump component parts. Refer to Cleaning and Inspection (Part 24-01) for the proper procedure. Replace all worn or damaged parts.

ASSEMBLY

The fuel pump assembly is shown in Figs. 2, 3 and 4.

1. Insert the rocker arm spring into the spring guide bore in the dome of the fuel pump rocker arm cavity.
2. Insert the rocker arm into the cavity and hook it onto the diaphragm rod directly below the rod flange. Position the rocker arm spring over the spring locator on the rocker arm.

Align the rocker arm pin holes and install the rocker arm pin. **Make certain the rocker arm spring is properly positioned on the spring locater on the rocker arm.**

3. Install a new rocker arm pin plug. Stake the plug into position.
4. Install the fuel filter assembly. Refer to Fuel Filter Replacement (Part 24-51) for the proper procedure.

PART 24-31 Fuel Pump—Electric

This Information Applies To: 330, 361, 391, 401, 477 and 534 CID Engines

COMPONENT INDEX	Page
CLEANING AND INSPECTION	31-02
FUEL PUMP ASSEMBLY	
Description	31-01
Installation	31-02
FUEL PUMP ASSEMBLY - Continued	
Removal	31-02
SPECIFICATIONS	31-02
TESTING	31-01

DESCRIPTION

The electric fuel pump used for the various truck models is the submerged-type, mounted in the fuel tank(s).

The pump has a completely enclosed dry motor. The motor operates the pump impeller by means of a magnetic coupling which protects the motor from burn-out should the impeller become locked. Since the pump does not depend upon the engine for power, it delivers a constant supply of fuel to the carburetor, eliminating fuel starvation periods during cranking or extreme high speed operation.

An electric primer switch, located on the instrument panel, is engaged before starting the engine. This actuates the fuel pump to fill the carburetor fuel bowl. An oil pressure safety switch shuts off the fuel pump when the engine stops or whenever engine oil pressure drops to a low level.

TESTING

Refer to Fig. 1.

1. Remove the air cleaner.
2. Disconnect the fuel line from the carburetor.
3. Using 1/4-inch pipe fittings, install a pressure gauge (0-15 psi), and a 1/4-inch gate valve to the carburetor fuel inlet line. Use of smaller than 1/4-inch fittings will restrict the fuel flow.
4. Install a flexible hose in the gauge valve so that the fuel can be expelled into a suitable container.
5. Operate the fuel pump with the primer switch. **Be sure the battery is fully charged.** Adjust the gate valve to obtain the specified pressure (Specifications Section in this Part). Expel the fuel into a suitable container. Engage the primer switch and observe the time required to expel one pint. Refer to the Specifications Section in this Part for the correct volume of fuel. **Timing must be started at the instant fuel is expelled from the hose and not when the primer switch is closed.**

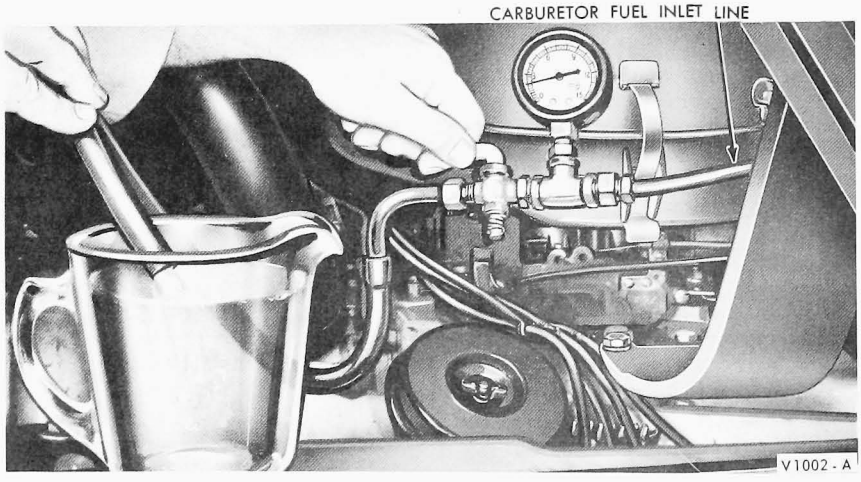

FIG. 1 Testing Electric Fuel Pump — Typical

6. If the fuel flow is below specified requirements, check the fuel pump at the outlet in the tank. This check will establish whether there is a restriction in the fuel line or the fuel pump is not working properly. At the fuel tank outlet, the fuel pump pressure and capacity should be within specifications. **The electric fuel pump is replaced as an assembly.**
7. Remove the test equipment and connect the fuel line.
8. Install the air cleaner.

REMOVAL AND INSTALLATION

FUEL PUMP ASSEMBLY

Removal

1. Disconnect the battery.
2. Disconnect the fuel outlet line at the fuel pump cover (Fig. 2). Remove the wire harness housing cover from the fuel pump cover. Disconnect the wires.
3. Remove the fuel pump cover and set it to one side.
4. Reach down into the fuel tank and disconnect the toggle clamp that secures the fuel pump in the retaining bracket and remove the fuel pump.
5. Disconnect the fuel outlet tube at the cover and fuel pump (Fig. 2). Remove the fuel pump wire assembly at the cover and fuel pump.

Installation

1. Remove the old gasket material from the fuel pump cover.
2. Position a new gasket on the cover.
3. Connect the fuel outlet tube to the cover and to the new pump (Fig. 3).
4. Connect the electric wire to the cover and the new pump.
5. Install the new fuel pump in the bracket in the tank. Fasten the toggle clamp.
6. Position the cover assembly on the tank and install the attaching screws and wire clamps. Connect the fuel line to the fitting on the cover (Fig. 4). Position the wiring harness in its housing on the cover (Fig. 3). Install the wire harness housing cover (Fig. 5).
7. Connect the battery.

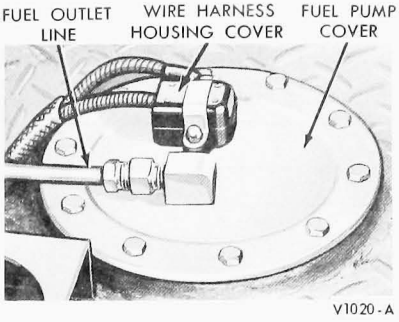

FIG. 2 Electric Fuel Pump Connections

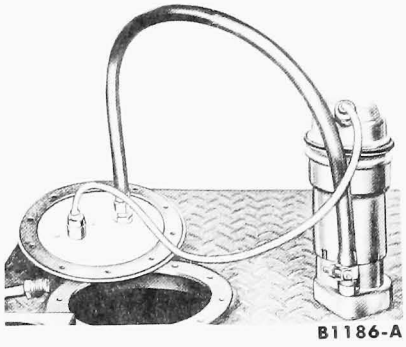

FIG. 3 Fuel Pump Installation

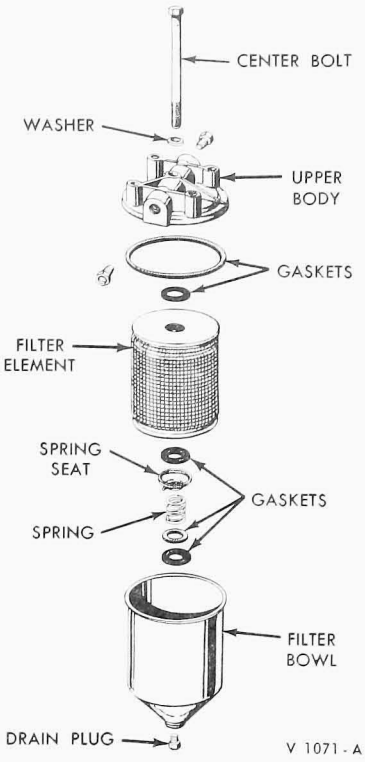

FIG. 4 Fuel Filter Assembly

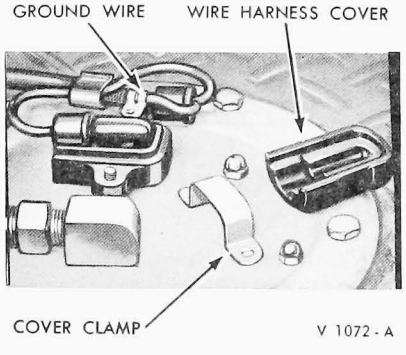

FIG. 5 Wiring Harness Installation

CLEANING AND INSPECTION

The electric fuel pump is replaced as an assembly and should not be disassembled for cleaning and inspection purposes. Refer to the Wiring Diagram Manual, Form 7795P-73, for schematics and locations of wiring harnesses and related parts.

PART 24-40 Air Cleaner—Oil Bath Type

This Information Applies To: All Gasoline Engines Except 170 CID

COMPONENT INDEX	Page	COMPONENT INDEX	Page
AIR CLEANER ELEMENT CLEANING	40-01	DESCRIPTION	40-01
AIR CLEANER OIL RESERVOIR	40-01	REMOVAL AND INSTALLATION	40-01

DESCRIPTION

Oil bath air cleaners are standard on all P, C, F and B-Series trucks and on L, LN, LT and LNT-Series trucks with 240, 300, 330, 361 and 391 CID engines. An optional oil bath air cleaner is available on Bronco with 302 CID engine, Econoline with 240 or 302 CID engine and F-100-350 with all engines.

Air from the air intake duct assembly enters the air cleaner. The air passes down between the outside walls of the air cleaner into the oil reservoir. The air is then deflected up through the filter element, and then down the center of the air cleaner to the carburetor. As the air rushes down across the oil and up, the large heavy dust particles fall into the oil. The smaller remaining dust particles are trapped in the oil-dampened filter.

REMOVAL AND INSTALLATION

Illustrations of the various types of air cleaners for the vehicle models and engine applications are shown in Figs. 1 thru 4 in Part 24-41. Reference to the illustrations will enable the mechanic to perform the required removal and installation and/or repair operations.

CLEANING AND INSPECTION

Clean the air cleaner oil reservoir and screen and refill with new oil at the recommended service interval.

Remove the oil reservoir from the air cleaner body and dispose of the oil. Clean the reservoir and screen with solvent or kerosene and dry with compressed air. Fill the reservoir with clean, fresh oil of the weight and grade used in the engine crankcase. Inspect the air cleaner element for dirt, leaves or other foreign material and clean as required.

Install the oil reservoir on the air cleaner.

AIR CLEANER ELEMENT CLEANING

Clean the filter element as required with kerosene or solvent (do not use gasoline) and drip dry. Wet the element with lubricating oil of the type used in the oil reservoir.

PART 24-41 Air Cleaner—Dry Type

This Information Applies To: All Gasoline Engines

COMPONENT INDEX	Page	COMPONENT INDEX	Page
AIR CLEANER BODY	41-09	Cleaning with Compressed Air	41-08
DESCRIPTION	41-01	Cleaning with Water	41-08
FILTER ELEMENT	41-08	REMOVAL AND INSTALLATION	41-01

DESCRIPTION

Dry type air cleaners are standard on all F-100-350, Bronco and Econoline Series trucks and on super duty engines in L, LN, LT and LNT series trucks. An optional dry type air cleaner is available on super duty engines in C-Series trucks and on 330, 361 and 391 CID engines in L, LN, LT and LNT series trucks. An air restriction gauge is installed on dry air cleaners used on super duty engines and on 330, 361 and 391 CID engines.

Air passes into the air cleaner and through a chemically treated and pleated paper element before entering the engine induction system.

REMOVAL AND INSTALLATION

Illustrations of the various types of air cleaners for the vehicle models and engine applications are shown in Figs. 1 thru 13. Reference to the illustrations will enable the mechanic to perform the required removal and installation and/or repair operations.

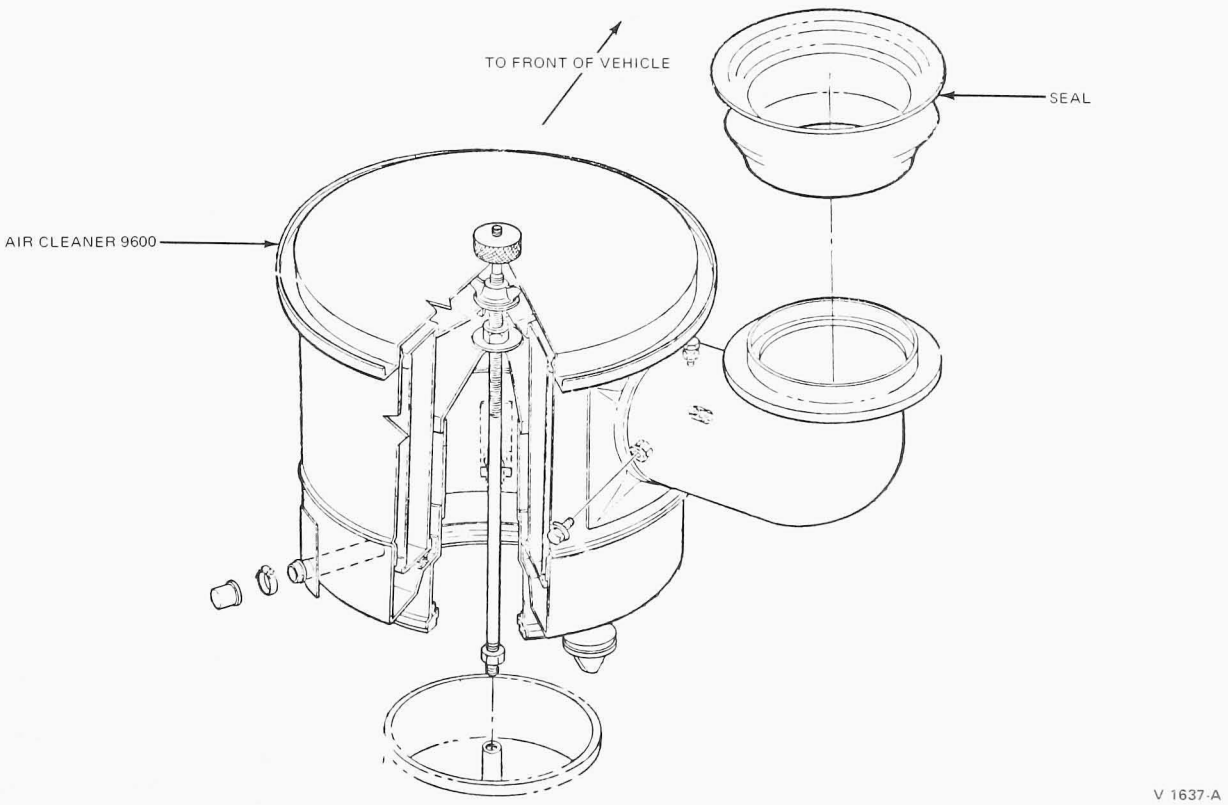

FIG. 12 Air Cleaner Assembly—F-6000-7000 Series

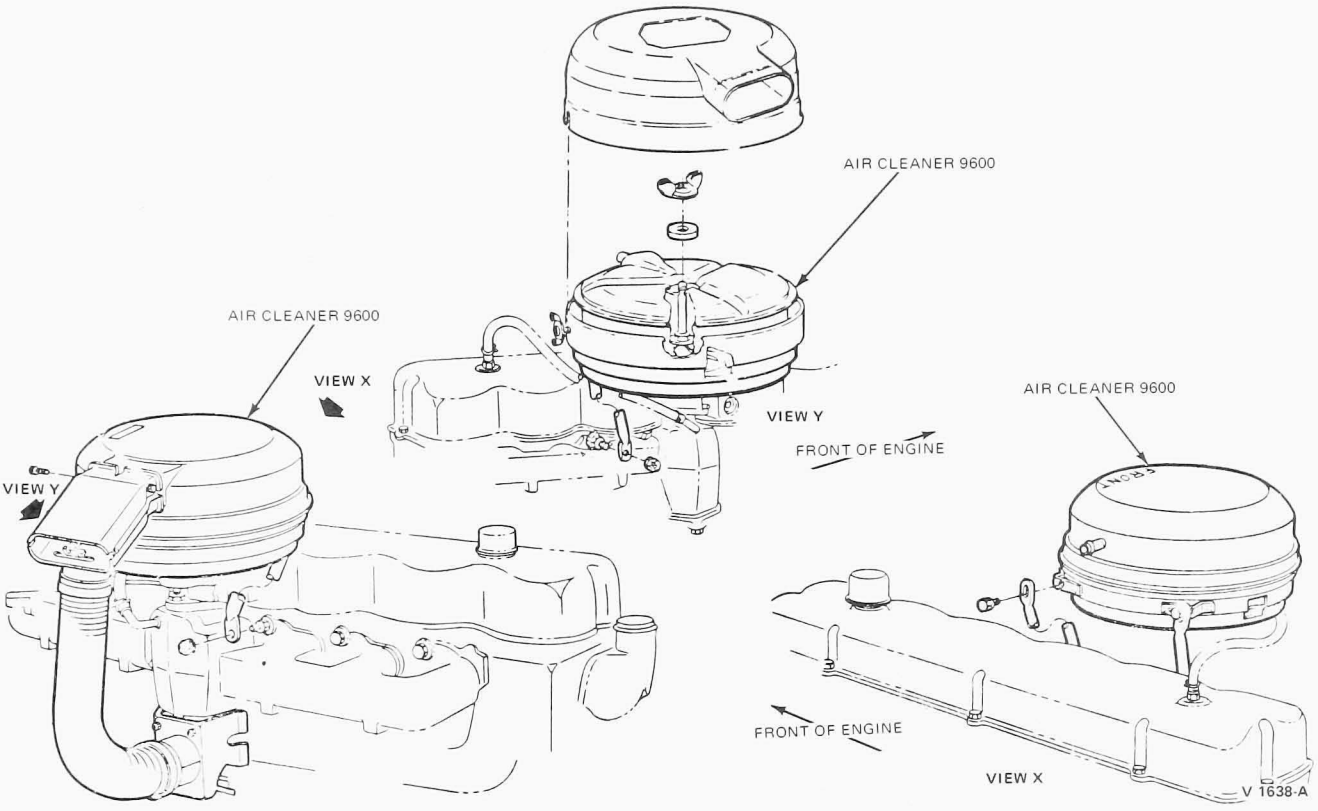

FIG. 13 Air Cleaner Assembly—B-N-600

CLEANING AND INSPECTION

Refer to the 1973 Truck Maintenance and Lubrication Manual for the recommended maintenance mileage interval.

Dry type air filter elements are normally replaced, however, dry type air cleaner elements used on 330, 361, 391 CID Medium and Heavy Duty engines and on 401, 477 and 534 CID Super Duty engines can be cleaned to prolong their service life.

An air restriction indicator (Fig. 14) is installed on the air cleaner. The indicator will read RED when the air cleaner restriction reaches 20 inches of water.

The restriction indicator must be reset after the air cleaner has been serviced.

Washing in water or blowing with compressed air are two accepted methods for cleaning elements of the Cyclopac air cleaners. If elements regularly contain substantial amounts of soot or oil fumes, washing in water works better than compressed air. If the contaminant on the element is mostly dust, either method works well. Elements that are cleaned with compressed air can be put back into service immediately. Washed elements must be dried before they are used.

Some elements are partially covered by a plastic sleeve with fins. The covered portion can be cleaned with water or air without removing the sleeve. Use a stiff fiber (not wire) brush to remove oil and grease deposits from the sleeve and fins. **Do not remove plastic sleeve and fins from the element.**

CLEANING

CLEANING WITH COMPRESSED AIR

1. Direct a jet of clean, dry air from the inside of the filter element, perpendicular to the pleats. **Pressure at air nozzle must not exceed 100 psi.**
2. Move the air jet up and down along the pleats, slowly rotating the element, until no more dust is being removed. **Be certain that the element is not ruptured by the nozzle or the air jet.**

CLEANING WITH WATER

The elements can be cleaned by washing with water and a good non-sudsing detergent. Direct a jet of clean, dry air from the inside of the filter element. When the loose dust and soot have been removed, the element is ready to be washed.

1. Dissolve the detergent in a small amount of cool water.
2. Add warm (approximately 100 degrees F) water to get the proper proportions of detergent and water (about one cup of detergent to five gallons of water).
3. Soak the element in the solution for at least 15 minutes.

4. Agitate the element for about 2 minutes to loosen the dirt.

Never use gasoline or solvents to clean elements.

5. Rinse the element with clean water until the water coming through the element is clean. Water pressure from a hose or tap should not be over 40 psi. Air-dry the element thoroughly before using.

Mechanized drying methods can be used. However, heated air (maximum temperature 180 degrees F) must have some circulation. **Do not use light bulbs for drying elements.**

6. After cleaning the filter element, using either air or water, inspect the element for damage. Look for dust on the clean air side, the slightest rupture, or damaged gaskets. A good method to detect ruptures in the element is to place a light inside the element and look toward the light from the outside. Any hole in the element, even the smallest, will pass dust to the engine and cause unnessary wear.

AIR CLEANER BODY CLEANING AND INSPECTION

Before re-installing the filter element, remove any foreign material (leaves, lint, or other foreign matter) that may have collected inside the air cleaner body. Inspect the inside of the body for dents or other damage that would interfere with air flow or with the fins on the element or inside the body. Repair body dents, being careful not to damage sealing surfaces.

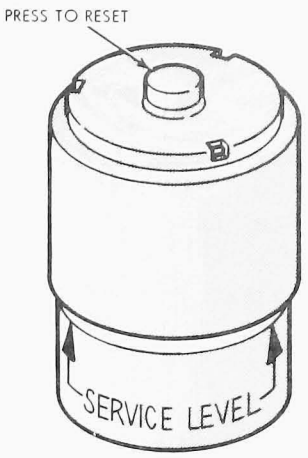

FIG. 14 Air Restriction Indicator

PART 24-42 Air Cleaner Duct Systems

This Information Applies To: All Gasoline Engines

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ASSEMBLY	42-02	REMOVAL	42-02
DESCRIPTION	42-01	TESTING	42-01
DISASSEMBLY	42-02		
INSTALLATION	42-02		

DESCRIPTION

Fresh air or heated air from a shroud around the exhaust manifold is available to the engine.

A thermostatic bulb in the air duct is exposed to the incoming air. A spring-loaded valve plate is connected to the thermostatic bulb. The valve plate spring holds the valve in the closed (heat on) position until the thermostatic bulb overcomes the valve spring tension.

During the engine warm-up period when the air entering the air duct is less than 75 degree F., the valve plate is held in the closed (heat on) position by the valve plate spring thus shutting off outside air. All air is then drawn from either the engine compartment or the shroud around the exhaust manifold.

As the temperature of the air passing the thermostatic bulb approaches 85 degrees F., the thermostat starts to expand, and pulls the valve plate down. This allows a combination of cooler outside air and heated air to enter the air cleaner. When the temperature of the heated air reaches approximately 100 degrees F., the valve plate will be in the down position (heat off) so that only outside air is allowed to enter the air cleaner.

Failure of this system to function will affect the vehicle exhaust emission control system and may result in failure of the vehicle to meet Federal emission regulations as well as affecting driveability.

To determine whether the system is functioning properly, the following procedure should be used:

DUCT AND VALVE ASSEMBLY

1. With the duct assembly installed on the vehicle, cold engine, and ambient temperature in the engine compartment of less than 100 degrees F, the valve plate should be in the **heat-on** position (Fig. 1).
2. If the plate is not in the **heat-on position, check for possible interference of plate and duct which would cause the plate to bind in its given travel. Correct by realigning the plate if interference is present.**
3. Remove the duct and valve assembly from the vehicle.
4. Immerse the duct assembly in cool (below 75 degrees F) water so that the thermostat capsule is covered with water.
5. Raise the water temperature to 100 degrees F, allow 5 minutes to stabilize temperature, and observe the valve plate position. The correct position should be in the **heat-on position (Fig. 1).**
6. Increase the water temperature to 135 degrees F, allow five minutes to stabilize the temperature, and observe the valve plate. The valve plate should be in the **heat-off position (Fig. 1).**

If the valve plate does not meet the requirements as outlined in steps 5 and 6, and no plate and duct interference is observed, the duct and valve assembly should be replaced.

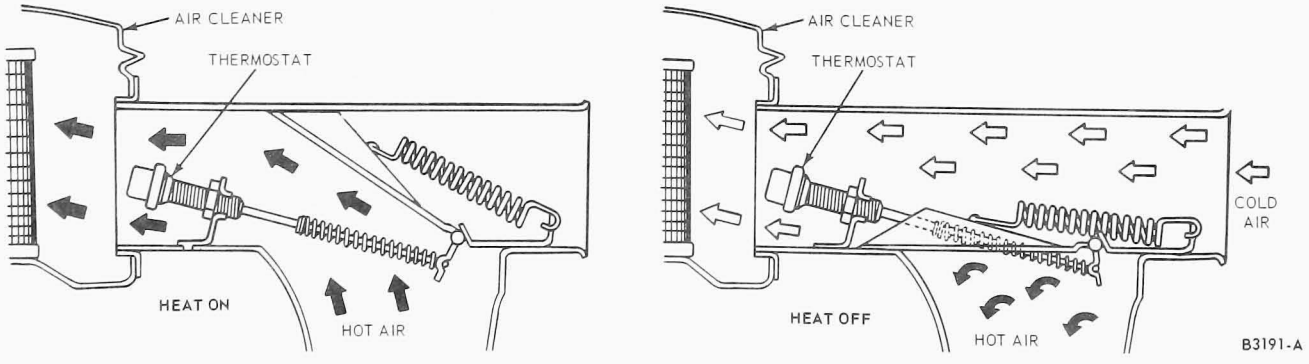

FIG. 1 Operation — Duct and Valve Assembly

REMOVAL AND INSTALLATION

DUCT AND VALVE ASSEMBLY

REMOVAL

1. Remove the retaining cap screws that secure the air intake duct and valve assembly to the air cleaner.
2. Remove the air intake duct and valve assembly from the engine.

INSTALLATION

1. Install the air intake duct and valve assembly on the shroud tube.
2. Connect the air intake duct and valve assembly to the air cleaner and tighten the retaining cap screws.

DISASSEMBLY AND ASSEMBLY

DUCT AND VALVE ASSEMBLY

DISASSEMBLY

1. If the duct and valve assembly was removed because of a suspected temperature malfunction, then check the operation of the thermostat and valve plate assembly. Refer to the Air Intake Duct Test under Testing in this Part for the proper procedure.
2. If inspection reveals that the valve plate is sticking or the thermostat is malfunctioning, remove the thermostat and valve plate as follows:

Detach the valve plate tension spring from the valve plate using long-nose pliers. Loosen the thermostat locknut and unscrew the thermostat from the mounting bracket. Grasp the valve plate and withdraw it from the duct.

ASSEMBLY

If it was necessary to disassemble the thermostat and air duct and valve, assemble the unit as follows:

1. Install the valve plate. Install the locknut on the thermostat, and screw the thermostat into the mounting bracket. Install the valve plate tension spring on the valve plate and duct.
2. Check the operation of the thermostat and air duct assembly. Refer to the Air Intake Duct Test under Testing in this Part for the proper procedure. Tighten the locknut.

DESCRIPTION

FUEL EVAPORATIVE EMISSION SYSTEM

All Bronco, Econoline and F-100 vehicles are equipped with a fuel evaporative emission system. This system is designed to limit fuel vapors released to the atmosphere.

On F-100 vehicles, the system consists of an evaporative emission type fuel tank, a U-shaped steel tube vapor vent chamber, a carbon canister, vapor vent tubes and various standard parts (Fig. 1). On F-100 vehicles equipped with an auxiliary fuel tank, the system uses an emission control valve rather than a vent chamber. This valve is located on top of the auxiliary tank (Fig. 2).

The Econoline fuel evaporative emission system makes use of an evaporative emission fuel tank, an emission control float valve, carbon canister, and vapor tubes (Fig. 3).

The Bronco fuel evaporative emission system makes use of an evaporative emission fuel tank, a vapor separator tank, and vapor tubes (Fig. 4).

On all vehicles, liquid fuel is prevented from entering the vapor lines by means of restricted orifices. In Econoline and F-100 vehicles equipped with aft-of-axle tanks the emission control valve prevents liquid fuel passage through the action of the float and needle valve inside the valve. In standard F-100 fuel tanks, the U-shaped

vapor vent chamber includes a 0.050 inch orifice while the Bronco uses a vapor separator tank as well as 0.050 inch orifice vapor tube to prevent liquid fuel from entering the vapor system. All vehicles use a carbon canister to store fuel vapor until it can be taken into the carburetor or cleaner and burned in the engine. In addition, all Bronco, Econoline, and F-100-350 vehicles make use of a fuel return line to assist in hot fuel handling. These lines run from the carburetor back to the fuel tank.

The fuel tanks for the various vehicle models are shown in Figs. 5 thru 11.

Refer to the specifications for the fuel tank usage and capacities for the various vehicle models.

The in-cab fuel tank is available on certain models of F-Series vehicles. It is located behind the drivers seat (Fig. 6). The fuel tank filler pipe extends from the left upper corner of the tank through the center rear quarter of the cab body. The filler pipe is connected to the tank with a rubber hose and two clamps. On a diesel engine equipped vehicle, the filler pipe connecting hose has an integral fitting for an attached fuel return hose and retaining clamp. A grommet insulates the filler pipe from the body. On a Diesel engine equipped vehicle, a grommet also insulates the fuel return line from the body. The fuel gauge sending unit and the fuel outlet line are mounted on the top of the tank. The tank is secured to the body in seven places as shown in Fig. 6. The tank does not contain a drain plug.

The rectangular, cylindrical, centerstep and full-step fuel tanks (Fig. 7) are located on the outside of the frame left and/or right side rail. The tanks are secured to the frame with brackets and straps. The fuel gauge sending unit and the fuel outlet line are located on the top of the tank.

The saddle fuel tank (Fig. 7) is mounted over the frame. The tank is secured to the frame with 4 bolts and brackets. Each side of the tank has a filler cap, fuel gauge sending unit and fuel outlet line mounted on the top of the tank.

The standard fuel tank for the F-Series Cowl Models or P-Series vehicles (Fig. 8) is mounted on insulated brackets and straps located inside the frame side rail. The fuel tank filler pipe extends from the lower left rear side of the tank, through the vehicle body. The filler pipe is connected to the tank with a rubber hose and two clamps. A grommet insulates the pipe from the body. The tank is vented into the filler pipe by a connecting air relief line that leads from the top of the tank to the filler pipe. The fuel gauge sending unit and fuel outlet line are mounted on the top of the tank. A drain plug is located at the bottom side of the tank.

The fuel systems for all vehicle models not equipped with a fuel evaporative emission control system are vented through the filler pipe cap. Fuel systems equipped with a fuel evaporative emission control system are vented to a carbon canister and then to the engine air cleaner.

The various fuel lines, clips, looms, fittings and insulators are fabricated to suit the individual vehicle series or models and engine requirements. Each of the components are replaceable.

Nylon fuel lines are used on C, CT, W and WT Series trucks. Special connecting parts (Fig. 12) are used when installing or connecting these lines. Gasoline and Diesel trucks each require a different type of nylon fuel line as indicated in the Specifications.

The frame mounted auxiliary fuel tank (Figs. 2 and 9) is an optional 24 gallon capacity tank which is available for F-100-250 (4 x 2) and F-350 trucks. Models with the fuel evaporative system have a 20.2 gallon capacity. The option is available only with the standard aft-of-axle tank. The frame mounted fuel tank is also available on the Camper Special. It is mounted on insulated brackets and straps located inside the frame rail similar to the standard in-frame installation.

The Econoline fuel tank is located behind the rear axle (Fig. 3). The fuel tank filler pipe extends from the left lower rear corner of the tank through the rear quarter of the body. The filler pipe is connected to the tank with a rubber hose and two clamps. The fuel gauge sending unit and fuel outlet line are mounted on the front of the tank.

The tank is secured to the body in four places with two support straps.

The fuel tank and lines and the optional fuel tank plate (shield) for the Bronco models are shown in Fig. 4. The 14-gallon capacity fuel tank and optional plate is located between the frame side members at the rear of the vehicle. The fuel tank filler pipe extends from the fuel tank, through the left rear quarter panel. The tank contains a fuel gauge sending unit and an attached fuel tank vent line. Insulators are used at the fuel tank supports, clamps and retaining strap.

The optional auxiliary 12-gallon capacity polyurethane fuel tank and lines, and the optional fuel tank plate (shield) are shown in Figure 10. The auxiliary tank and plate are located between the frame members under the drivers seat. The fuel tank filler pipe extends from the fuel tank through the left side panel. The tank contains a fuel gauge sending unit which is connected to a switch on the instrument panel to provide metering of fuel quantity in either tank. A manual mixing valve is installed on the floor pan under the front seat to allow the driver to select fuel to be pumped from either or both tanks.

REMOVAL AND INSTALLATION

IN-CAB FUEL TANK

A typical fuel tank installation is shown in Figs. 1 and 6. Refer to the specifications for the capacities and usage.

Removal

1. Insert a siphon through the filler neck and drain the fuel into a suitable container.
2. Move the seat to the full forward position, and tilt the back of the seat forward.
3. Disconnect the fuel gauge sending unit wire and the fuel line. On a vehicle equipped with a fuel evaporative emission control system, disconnect the vapor vent chamber and vapor lines from the fuel tank (Fig. 1).
4. On a truck so equipped, disconnect the fuel return line.
5. Loosen the filler neck hose clamp at the tank end of the hose, and then pull the filler neck away from the tank.
6. Remove the fuel tank retaining bolts and nuts (Figs. 1 and 6). Lift the tank out of the cab. Replace all worn or damaged parts and insulators.
7. If the tank is to be replaced, remove the fuel gauge sending unit pressure relief tube (if so equipped) and gasket. Discard the gasket.

Installation

1. If the fuel tank has been replaced, install the fuel gauge sending unit pressure relief tube (if so equipped) and a new gasket. Glue new anti-rattle insulating material onto the new fuel tank. If required, glue three new rubber pads in place in the channel at the bottom of the tank. If required, glue new washers to the body at the mounting bolt holes.
2. Position the tank in the cab and install the nuts at the top and capscrews at the bottom of the tank.
3. Connect the fuel line, the fuel gauge sending unit wire and the filler neck hose. On a vehicle with a fuel evaporative emission control system, connect the fuel tank to vapor vent chamber and vapor tubes.
4. On a vehicle with a Diesel engine, connect the fuel return line.
5. Fill the fuel tank with fuel, and install the filler cap. Start the engine and check for leaks.
6. Stop the engine, tilt the back of the seat rearward and adjust the seat position.

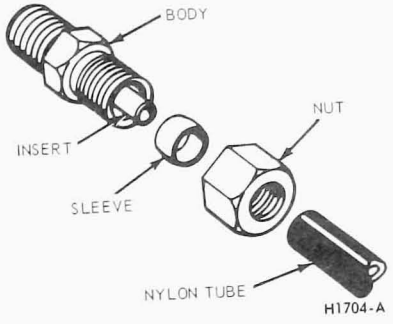

FIG. 12 Nylon Fuel Line Connection

OUTSIDE-FRAME FUEL TANKS

Typical fuel tank installations are shown in Fig. 7. Refer to the specifications for the capacities and usage.

Removal

1. Drain the fuel into a suitable container by either removing the drain plug (if so equipped) or by siphoning through the filler cap opening.
2. Disconnect the fuel line and the fuel gauge sending unit wire. Disconnect the electric fuel pump wires if so equipped.
3. On a vehicle so equipped, disconnect the fuel return line.
4. On a vehicle with dual fuel tanks, disconnect the fuel line connecting the tanks.
5. If the tank is equipped with a filler neck and connecting hose, loosen the hose retaining clamp at the tank, and pull the hose away from the tank.
6. Remove the fuel tank strap retaining bolts and remove the straps. Remove the tank. Replace all worn or damaged parts.
7. If the fuel tank is to be replaced, remove the fuel gauge sending unit and gasket from the tank. Remove the shut-off valve assembly if so equipped. Discard the gasket. Remove the electric fuel pump if so equipped.

Installation

1. If the fuel tank has been replaced, install the fuel gauge sending unit and a new gasket on the tank. Install the shut-off valve assembly, if so equipped. Install the electric fuel pump and a new gasket if so equipped. Position new insulating strips on the fuel tank. Install the drain plug (if it was removed) in the fuel tank.
2. Install the fuel tank on the mounting brackets.

If the tank is equipped with a filler neck and connecting hose, position the hose and clamp on the tank and tighten the hose.

3. Install the retaining straps, but do not tighten the mounting bolts. Align the tank. Make certain the insulators are properly centered under the straps and brackets. Tighten the retaining strap mounting bolts.
4. Connect the fuel line to the tank. Connect the fuel gauge sending unit wire. Connect the electric fuel pump wires if so equipped.
5. On a vehicle with dual fuel tanks, connect the fuel line connecting the tanks.
6. On a vehicle with a Diesel engine, connect the fuel return line.
7. Fill the tank with fuel and install the filler cap. Start the engine and check for leaks.

SADDLE TANK

A typical fuel tank installation is shown in Fig. 7. Refer to the specifications for the capacities and usage.

Removal

1. Drain both sides of the tank into a suitable container.
2. Disconnect the sending wires from the fuel gauges and the fuel inlet lines. Disconnect the electric fuel pump wires if so equipped. Position the lines and wires out of the way.
3. Remove the nuts and bolts retaining the air line and hose bracket to the forward edge of the tank.
4. Remove the bolt, nut, flat washer and spring from each fuel tank mounting bracket.
5. Hook a lifting chain to the 4 corners of the fuel tank (near the mounting brackets) and remove the tank with a hoist.

Installation

1. If a replacement tank is being installed, remove the fuel gauge sending units from the old tank and install them, with new gaskets, in the replacement tank. Remove the electric fuel pumps, if so equipped, from the old tank and install them, with new gaskets, in the replacement tank.

2. Inspect the insulator pads and replace them if they are damaged.
3. Using a hoist, position the tank on the vehicle.
4. Remove the hoist and lifting chain.
5. Install the retaining bolt, washer, spring and nut on each mounting bracket.
6. Install the air line and hose support bracket retaining bolts, washers and nuts.
7. Connect the sending wires to the fuel gauges and the fuel lines to the connectors. Connect the electric fuel pump wires if so equipped.
8. Replace the fuel.
9. Start the engine and check for leaks.

IN-FRAME FUEL TANK

A typical fuel tank installation is shown in Figs. 1 and 8. Refer to the specifications for the capacities and usage.

Removal

1. Drain the fuel into a suitable container by either removing the drain plug (if so equipped) or by siphoning through the fuller cap opening. Also, on F-100, 250 and 350 models, remove the spare tire if located under the fuel tank.
2. Disconnect the fuel gauge sending unit wire and the fuel outlet line.
3. On a vehicle with a Diesel engine, disconnect the fuel return line.
4. Disconnect the air relief tube from the filler neck and the fuel tank.
5. Loosen the filler neck hose clamp at the fuel tank and pull the filler neck away from the tank.
6. Remove the retaining strap mounting bolts and nuts, and lower the tank to the floor. Replace all worn or damaged parts.
7. If the tank is to be replaced, remove the fuel gauge sending unit and gasket from the tank. Discard the gasket.

Installation

1. If the fuel tank has been replaced, install the fuel gauge sending unit and a new gasket on the tank. Position new insulating strips on the fuel tank. Install the drain plug in the fuel tank (if required).
2. Position the straps around the tank. Install the tank and straps on the support bracket. Align the tank. **Make certain the insulators are centered properly under the straps and mounting brackets.** Tighten the strap retaining bolts.
3. Position the filler neck clamp and hose on the fuel tank and tighten the clamp.
4. Connect the air relief tube to the filler neck and tank. Connect the fuel line to the tank. Connect the fuel gauge sending unit wire.
5. On a vehicle with a Diesel engine, connect the fuel return line.
6. Fill the tank with fuel and install the filler cap. If the spare was removed, install it. Start the engine and check for leaks.

UNDER-CAB AUXILIARY FUEL TANK

A typical fuel tank installation is shown in Figs. 2 and 9. Refer to the specifications for the capacities and usage.

Removal

1. Drain the fuel into a suitable container by inserting a syphon through the filler neck.
2. Remove the clamps and disconnect the hoses attached to the fuel tank. On a vehicle equipped with a fuel evaporative emission control system, disconnect the vapor lines from the emission control valve.
3. Remove the nuts and bolts from the retaining straps, and lower tank to floor. Replace any worn or damaged parts.

Installation

1. Position retaining straps around fuel tank and attach bolts and nuts.
2. Connect the hoses to the tank and tighten the clamps. On a vehicle equipped with a fuel evaporative emission control system connect the vapor lines to the emission control valve located in the top of the tank.
3. Fill tank with fuel and check for leaks.

ECONOLINE FUEL TANK

The Econoline fuel tank installation is shown in Fig. 3.

Removal

1. Raise the rear of the vehicle.
2. **To avoid electrical sparking at the tank, disconnect the ground cable on the vehicle battery.** Then disconnect the fuel gauge sending unit wire at the fuel tank.
3. Remove the fuel tank drain plug and drain the fuel into a suitable container.
4. Loosen the hose clamps, slide the clamps forward and disconnect the fuel line at the fuel gauge sending unit. Disconnect the fuel tank vapor lines by removing the clamps at the emission control valve.
5. If the fuel gauge sending unit is to be removed, turn the unit retaining ring counterclockwise and remove the sending unit, retaining ring, and gasket.
6. Loosen the clamp on the fuel filter pipe hose at the tank, and disconnect the hose at the tank and disconnect the hose from the tank.
7. Remove the strap retaining nut at each tank mounting strap, swing the strap down, and lower the tank enough to gain access to the tank vent hose.
8. Disconnect the fuel tank vent hose at the top of the tank.
9. Lower the fuel tank, and remove it from under the vehicle.

Installation

Make sure all mating surfaces are clean.

1. Position the forward edge of the tank to the frame crossmember, and connect the vent hose to the top of the tank.
2. Position the tank and mounting straps, and install the retaining nuts and flat washers.
3. Connect the filler pipe-to-tank hose at the tank and install the hose clamp.
4. If the fuel gauge sending unit was removed, make sure all the old gasket material has been removed from the unit mounting surface on the fuel tank. Using a new gasket, position the fuel gauge sending unit to the fuel tank and secure with the retaining ring.
5. Connect the fuel gauge sending unit wire to the sending unit.
6. Connect the fuel line at the fuel gauge sending unit and tighten the hose clamps securely. Install the drain plug.

Connect the fuel tank to vapor lines at the emission control valve located on top of the tank.

7. Connect the vehicle battery ground cable removed in Step 2 of the removal procedure (above).
8. Fill the tank and check all connections for leaks.
9. Lower the vehicle.

BRONCO FUEL TANK

Removal

Use the following procedure to remove either the main or auxiliary fuel tanks.

1. Insert a siphon through the filler neck and drain the fuel into a suitable container.
2. Raise the rear of the vehicle. (For removal of the auxiliary tank, raise the left side of the vehicle.)
3. To avoid electrical sparking at **the tank, disconnect the ground cable on the vehicle battery.** Then disconnect the fuel gauge sending unit wire at the fuel tank.
4. Loosen the clamp on the fuel filler pipe hose at the filler pipe and disconnect the hose from the pipe.

5. Loosen the hose clamps, slide the clamps forward and disconnect the fuel line at the fuel gauge sending unit.
6. If the fuel gauge sending unit is to be removed, turn the unit retaining ring, and gasket.
7. Remove the strap attaching nut at each tank mounting strap, swing the strap down, and lower the tank enough to gain access to the tank vent hose.
8. Disconnect the fuel tank vent hose at the top of the tank.

Disconnect the fuel tank to separator tank lines at the fuel tank.

9. Lower the fuel tank and remove it from under the vehicle.

Installation

Use the following procedure to install either the main or auxiliary fuel tank. **Make sure all mating surfaces are clean.**

1. Position the forward edge of the tank to the frame crossmember, and connect the vent hose to the top of the tank.

Connect the fuel tank to separator tank lines at the fuel tank.

2. Position the tank and mounting straps, and install the attaching nuts and flat washers.
3. If the fuel gauge sending unit was removed, make sure all the old gasket material has been removed from the unit mounting surface on the fuel tank. Using a new gasket, position the fuel gauge sending unit to the fuel tank and secure with the retaining ring.
4. Connect the fuel line at the fuel gauge sending unit and tighten the hose clamps securely. Install the drain plug, if so equipped.
5. Connect the fuel gauge sending unit wire to the sending unit.
6. Connect the filler pipe-to-tank hose at the filler pipe and install the hose clamp.
7. Connect the vehicle battery ground cable removed in Step 2 of the removal procedure (above).
8. Fill the tank and check all connections for leaks.
9. Lower the vehicle.

FILLER PIPE-IN CAB FUEL TANKS

Removal

1. Insert a siphon through the filler pipe and drain the fuel tank to a level (approximately 3/4 full) below the fuel tank filler connection (Figs. 1 and 6).
2. Move the seat to the full forward position, and tilt the back of the seat forward. On a Diesel engine equipped vehicle, loosen the clamp and disconnect the fuel return hose from the filler pipe hose.
3. Loosen the filler pipe hose clamps. Pull the hose and filler pipe away from the tank. Remove the clamps, hose, grommet and filler pipe from the truck.
4. Replace all worn or damaged parts.

Installation

1. Position the hose and clamps on the filler pipe (Figs. 1 and 6). Position the grommet on the filler pipe. Position the filler pipe assembly in the cab and connect the hose to the tank filler opening.
2. Adjust the hose to obtain a snug filler pipe installation and tighten the hose clamps. **Make certain the clamps are forward of the flange on the filler pipe and tank, to insure a leak proof connection.**

On a Diesel engine equipped vehicle, connect the fuel return line to the filler pipe hose and tighten the retaining clamp.

3. Fill the tank with fuel to a level above the hose. Install the filler cap, and check for leaks.
4. Tilt the back of the seat rearward and adjust the seat position.

FILLER PIPE-IN FRAME FUEL TANKS

Removal

1. Remove the filler pipe cap. Remove the drain plug and completely drain the fuel tank.
2. Disconnect the air tube at the filler neck (Fig. 8). Loosen the filler pipe hose clamps. Pull the filler pipe assembly away from the tank and remove it from the vehicle.
3. Remove the hose and clamps. Replace all damaged or worn parts.

Installation

1. Position the hose and clamps on the filler pipe, and position the filler pipe assembly on the tank filler opening (Fig. 8). Align the filler pipe with the air tube connection.
2. Adjust the hose to obtain a snug filler pipe installation and tighten the hose clamps. **Make certain the clamps are forward of the flange on the filler neck and the tank opening to ensure a leakproof connection.** Connect the air tube to the filler pipe. Install the drain plug.
3. Fill the tank with fuel. Install the filler cap, and check for leaks.

FILLER PIPE—ECONOLINE

Removal

1. Drain tank to a level below the filler pipe. Raise the rear of the truck and loosen the lower clamp on filler pipe to tank hose. On a vehicle equipped with a fuel evaporative emission control system, loosen the filler tube vent hose clamp at the tank.
2. Open the filler pipe access door in the quarter panel and remove the screws that retain the filler pipe to the quarter panel.
3. Remove the filler pipe and hose from the quarter panel and fuel tank.
4. Loosen the hose clamp at the filler pipe and remove the hose from the filler pipe.

Remove the filler tube vent hose from the filler pipe, if so equipped.

Installation

1. Install the hose on the replacement filler pipe and secure with the hose clamp.

Install the filler tube vent hose on the filler pipe, if so equipped, and tighten the clamp.

2. Install the filler pipe and hose, and secure the filler pipe to the quarter panel with the retaining screw.
3. Position the lower hose clamp on the hose, connect the hose to the fuel tank inlet, and secure with the hose clamp.

On a vehicle equipped with a fuel evaporative emission control system, connect the filler tube vent hose to the fuel tank and tighten the clamp.

FILLER PIPE—BRONCO

Removal

Use the following procedure to remove either the main or the auxiliary fuel tank filler pipe.

1. Drain the tank to a level below the filler pipe. Raise the vehicle and loosen the lower clamp on the filler pipe to tank hose. Loosen the clamp on the filler vent tube hose at the tube.
2. Remove the screws that retain the filler pipe to the vehicle panel.
3. Remove the filler pipe and hose from the fuel tank. Slide the pipe out of the panel opening.
4. Loosen the hose clamp at the filler pipe and remove the hose from the filler pipe.

Installation

Use the following procedure to install either the main or the auxiliary fuel tank filler pipe.

1. Install the hose on the replacement filler pipe and secure with the hose clamp. Make sure all surfaces are clean.
2. Slide the filler pipe and hose into the hole in the panel. Slip the lower hose clamp on the hose and align the hose with the fuel tank filler pipe. Push

the hose onto the filler pipe.
3. Secure the filler pipe to the panel with the retaining screws.
4. Position the lower hose clamp over the fuel tank filler pipe stub, and tighten the hose clamp securely.

Connect the filler vent tube hose at the vent tube and tighten the clamp.
5. Fill the tank above the hose connections and check for leaks.
6. Lower the vehicle.

FUEL LINES—METAL

The various fuel lines are not serviced as assemblies. They must be cut, squared, and formed out of fuel system tubing and hose material available at dealerships.

A damaged section of tubing longer than 12 inches can be cut out of the existing line and replaced by service hose and two retaining clamps. All replacement hoses must be cut to a length that will ensure proper clamp retention beyond the ends of the connecting tubing.

Removal

1. Disconnect the fuel line(s) at both ends and remove the unit(s) from the holding clip(s), and the truck.
2. Slide the loom(s) (if used) off the line(s). Replace all worn or damaged parts.

Installation

1. Use the same diameter tubing as the original installation(s), and shape the new line(s) to the contour of the original line(s). Avoid sharp bends.
2. Cut the new line(s) to approximately the same length as the original line(s). Allow an additional length for the flaring operation.
3. Square off the ends with a file, and ream the sharp edges with the reamer blade on the tube cutter.
4. Position the new loom(s) (if used) on the new line(s). Place new connections on the line, if required, and flare the ends of the line(s) with a flaring tool. **When attaching new line to fuel pump or any other fitting, be sure to use a double lap flare in the line.** Be sure metal chips are removed from inside the tubing.
5. Install the connecting hoses and clamps (if required) on the fuel line(s). Position the line(s) in the clip(s) on the vehicle, and tighten the connection(s). Tighten the connecting hose clamps, if so equipped.
6. Check the connections for leaks.

FUEL LINES—NYLON

Inspect lines for kinking which might reduce fuel flow. Kinked lines should be replaced. Refer to the Specifications for type of nylon tubing used on gasoline or Diesel powered trucks.

Minimum bend radii for different sizes of tubing are shown in the specifications.

Removal and Installation

These lines are coupled to metal fittings in the same general manner as metal-to-metal connections, except that a plastic insert (Fig.9) must be used to prevent collapse of the tube. In addition, the sleeve shown in Fig. 11, which is similar to the ferrule used on metal tubes, is also made of nylon to prevent cutting the plastic tube. When making a new connection or installing a line, be sure that the tubing is cut square. Then the tube and insert must be bottomed in the body and held in place while tightening the tube nut to specifications.

PART 24-51 Fuel Filters

Applies To All Gasoline Engine Trucks

COMPONENT INDEX	Page	COMPONENT INDEX	Page
FUEL FILTERS		In-Line Filter with Electric Pump	
Description	51-01	500-800 Series	51-02
Fuel Pump with Integral Filter	51-02	In-Line with Electric Pump	
In-Line Filter – Bronco and Econoline	51-02	850-900 Series	51-02

DESCRIPTION

The fuel filters for mechanical fuel pumps are integrally mounted on the fuel pump except for the Bronco and Econoline and vehicles with electrical fuel pump systems.

Replace the in-line fuel filter assembly or the replaceable filter element (Figs. 1, 2 and 3) if either type becomes clogged, and also at the recommended maintenance mileage interval.

The integral fuel filter elements are not interchangeable between 6 and 8 cylinder fuel pumps. Refer to specifications for correct part number and follow instructions that come with element for proper installation.

Refer to the 1973 Truck Maintenance and Lubrication Manual for the recommended maintenance mileage interval.

On 100-800 Series vehicles, replace the filter element at the recommended maintenance mileage interval or whenever it becomes clogged.

On 900 Series vehicles, the drain plug at the bottom of the fuel filter bowl should be removed to drain the bowl, and filter element and gaskets should be replaced at the recommended maintenance mileage interval.

The electric fuel pump is replaced as an assembly and should not be disassembled.

Refer to Wiring and Vacuum Diagram Manual Form 7795P-73 for schematics and locations of wiring harnesses and related parts.

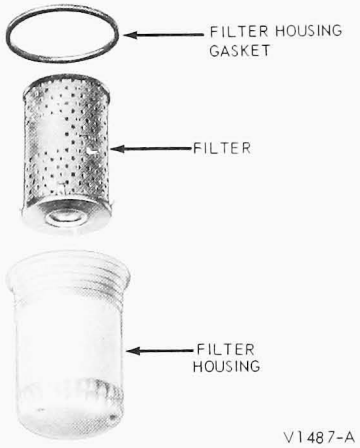

FIG. 1 Typical Fuel Filter with Replaceable Filter Element

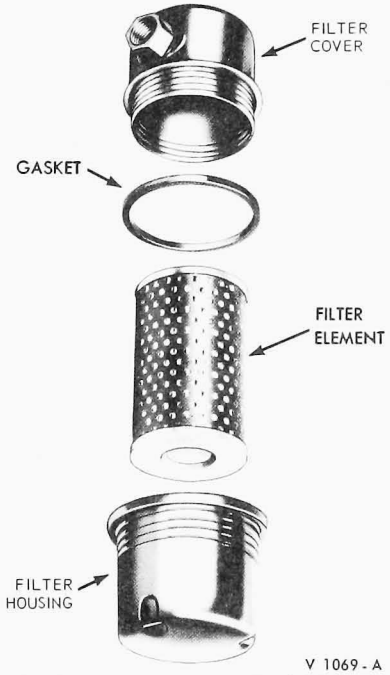

FIG. 2 Typical In-Line Fuel Filter Used with Electric Fuel Pump—500-800 Series

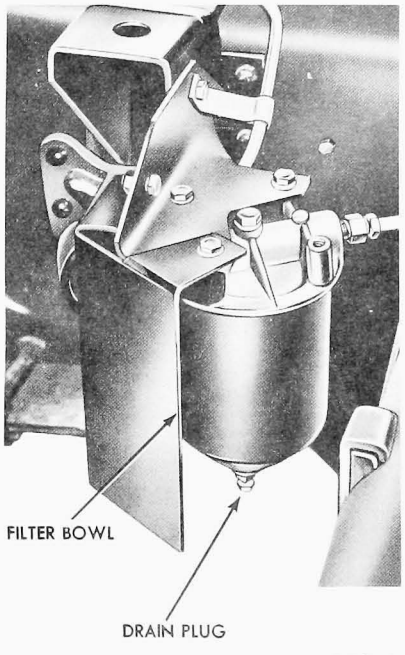

FIG. 3 Fuel Filter—Electric Fuel Pump—900 Series

REMOVAL AND INSTALLATION

IN-LINE FUEL FILTER—BRONCO AND ECONOLINE

The in-line fuel filter is of one-piece construction and cannot be cleaned. Replace the filter if it becomes clogged or restricted.

1. Remove the air cleaner (Parts 24-40 or 24-41).
2. Loosen the retaining clamp securing the fuel inlet hose to the fuel filter.
3. Unscrew the fuel filter from the carburetor. Disconnect the fuel filter from the hose and discard the retaining clamp.
4. Install a new clamp on the inlet hose and connect the hose to the filter. Screw the filter into the carburetor inlet port. Tighten the filter.
5. Position the fuel line hose clamp and crimp the clamp securely.
6. Start the engine and check for fuel leaks.
7. Install the air cleaner.

FUEL PUMP WITH INTEGRAL FUEL FILTER

1. Unscrew the filter housing from the fuel pump, and remove the filter element and gasket. Discard the element and gasket. Clean the filter housing in cleaning solvent.
2. Place a new filter element over the spout in the fuel pump valve housing cover. **Be sure to use the proper type element for the installation.** Coat a new gasket with light engine oil and position the gasket on the filter housing (Fig. 1). Screw the filter housing onto the fuel pump. Hand tighten the filter housing until the gasket contacts the pump, and then advance it 1/8 turn.
3. Start the engine and check for leaks.

IN-LINE FUEL FILTER—900 SERIES—WITH ELECTRIC FUEL PUMP

1. Unscrew the lower section from the upper section and remove the filter element and gasket (Fig. 2). Discard the element and gasket.
2. Clean the lower section in cleaning solvent. Clean the upper section with a cloth.
3. Coat a new gasket with light engine oil and position the gasket on the lower section.
4. Place a new filter element in the lower section.
5. Screw the lower section onto the upper section until the gasket contacts the upper section. Turn the lower section an additional 1/8 turn.

IN-LINE FUEL FILTER—850-900 SERIES—WITH ELECTRIC FUEL PUMP

1. Remove the drain plug from the filter bowl, and drain the fuel from the bowl into a suitable container (Fig. 3).
2. Remove the center bolt and washer, then remove the filter bowl and mounting gasket. Remove the filter element, gaskets, spring and spring seat.
3. Discard the filter element and gaskets. Clean the filter lower section in cleaning solvent. Clean the upper section with a cloth.
4. Position the spring seat, spring and new lower gaskets in the filter bowl as shown in Fig. 4. Install a new element in the filter bowl. Position the filter and new upper gaskets against the upper body. Install and tighten the center bolt and washer to specifications.

ADJUSTMENTS

200 SIX ENGINE—BRONCO

MANUAL TRANSMISSION

1. Disconnect the pin from the stabilizer rod and pull the rod from the bracket on the dash (Fig. 1).
2. Disconnect the rod from the bellcrank.
3. Insert a 3/16 diameter inch pin through the three holes in the bellcrank and bracket.
4. Thread the stabilizer rod into the bellcrank until the rod will enter the bracket on the dash.
5. Connect the stabilizer to the bracket using the pin, the remove the gauge pin.
6. Bring the throttle arm to the wide open position by pushing rearward on the bellcrank.
7. Adjust the length of the rod assembly so its forward end surface just touches the side of the bellcrank ball, then connect the rod.

240 SIX ENGINE—ECONOLINE

MANUAL TRANSMISSION

1. Remove four engine cover to floor bolts and unlatch the cover at either side. Remove the cover.
   Remove the air cleaner assembly.
2. Hold the accelerator pedal downward at the wide-open throttle position and check the position of carburetor throttle plate.

3. If the throttle plate is not wide-open with the accelerator pedal fully depressed, loosen the throttle cable retaining clip at the accelerator bracket (Fig. 3). With the accelerator pedal fully depressed, adjust the cable housing inward or outward until the throttle plate is in the wide-open position. Tighten the throttle cable bracket retaining clip.
4. **Check the accelerator linkage for proper operation.** Install the air cleaner assembly. Install the engine compartment cover.

AUTOMATIC TRANSMISSION

Instructions for adjusting the Automatic Transmission throttle linkage are given in Fig. 3.

302 V-8 ENGINE—BRONCO

MANUAL TRANSMISSION

The throttle (accelerator) linkage and hand operated throttle control linkage are shown in Fig. 4.

The throttle control linkage is adjusted using the following procedure:

1. Install the accelerator rod to the shaft assembly.
2. Depress the accelerator pedal to the floor by pushing the accelerator rod toward the dash panel.
3. Rotate the carburetor throttle lever to the wide open position against the stop.
4. Adjust the accelerator rod until the forward end surface of the throttle lever ball stud. Connect the accelerator rod to the throttle lower ball stud.

The hand throttle control linkage is adjusted using the following procedure:

1. Install hand throttle cable control wire into trunnion on throttle lever and tighten clamp screw.
2. Depress hand throttle cable control knob on instrument panel until it stops.
3. Move carburetor throttle lever against idle stop.
4. Slide hand throttle cable in cable clamp until throttle lever contacts pedal shaft arm.
5. Tighten cable clamp screw.

302 V-8 ENGINE—ECONOLINE

MANUAL TRANSMISSION

1. Remove four engine cover to floor bolts and unlatch the cover at either side. Remove the cover. Remove the air cleaner assembly.

Refer to Fig. 5 for identification of the throttle linkage components.

2. Insert a 3/16 inch diameter alignment pin through the accelerator shaft to carburetor assembly bracket.
3. Adjust the length of the stabilizer rod so that the trunnion enters freely; then install the clevis rod end clip and remove the alignment pin.
4. Depress the accelerator pedal to the floor; then bring the carburetor throttle lever to wide open throttle by adjusting the accelerator shaft to carburetor rod.
5. When the rod is adjusted to fit on the ball studs of the accelerator shaft lever and accelerator cross-shaft, shorten the rod by one turn and install on lever and shaft.
6. **Check the accelerator linkage for proper operation.** Install the air cleaner assembly. Install the engine compartment cover.

AUTOMATIC TRANSMISSION

Instructions for adjusting the automatic transmission throttle linkage are given in Fig. 5.

P-350 THRU 500 SERIES WITH 240 SIX AND 300 LD SIX

MANUAL TRANSMISSION

Refer to Fig. 6.

1. Adjust the engine idle (hot engine) speed and mixture to specification (refer to appropriate carburetor or Part of this Group). Shut off the engine.
2. Loosen the jam nut and adjust the accelerator pedal stop bolt to the specified clearance. Tighten the jam nut.
3. Disconnect the accelerator retracting spring. Loosen the accelerator cable bracket clip screw.
4. Depress the accelerator pedal to the pedal stop bolt; slide the accelerator cable assembly rearward until the carburetor throttle lever is in the wide open throttle position (fully open) and tighten the cable housing bracket clip screw.
5. Connect the accelerator retracting spring.
6. Start the engine and operate the accelerator to check for binds or improper operation.

AUTOMATIC TRANSMISSION

Instructions for adjusting the automatic transmission throttle linkage are given in Fig. 6.

F-100 THRU 350, F-100, 250 (4 x 4) WITH 240 AND 300 SIX

MANUAL TRANSMISSION

Refer to Fig. 7.

1. Disconnect pin at end of stabilizer rod and disconnect the rod from the bracket at the dash.
2. Disconnect the rod assembly from the bellcrank.
3. Insert a 3/16 inch dia. pin thru the three holes in bellcrank control and bracket assembly.
4. Adjust length of stabilizer assembly so that rod end enters bracket freely.
5. Install pin at end of stabilizer rod.
6. Remove gauge pin.
7. Depress accelerator pedal to floor.
8. Bring carburetor throttle lever to wide open position (against stop), by pushing rearward on the bellcrank assembly near the point where it attaches to the rod assembly.
9. Adjust rod assembly so its forward end surface just touches the side of the bellcrank assembly and connect the rod to the bellcrank.

AUTOMATIC TRANSMISSION

Instructions for adjusting the automatic transmission throttle linkage are given in Fig. 7.

F-100 THRU 350 WITH 302, 360 AND 390 V-8

MANUAL TRANSMISSION

Refer to Fig. 8.

1. Install the accelerator rod to the shaft assembly.
2. Depress the accelerator pedal to the floor by pushing the accelerator rod toward the dash panel.
3. Rotate the carburetor throttle lever to the wide open position against the stop.
4. Adjust the accelerator rod until the forward end surface of the rod just touches the rear surface of the throttle lever ball stud. Connect the accelerator rod to the throttle lower ball stud.

F-AND B-500 THRU 600 SERIES WITH 240 SIX AND 300 SIX

MANUAL TRANSMISSION

Refer to Fig. 9.

1. Adjust the engine idle (hot engine) speed and fuel mixture to specification (refer to appropriate carburetor Part of this Group). Shut off the engine.

2. Loosen the hand throttle cable clip retaining screw and adjust the hand throttle cable housing to the specified dimension, if required.
3. Loosen the cable housing clip. Push the accelerator pedal down to the pedal stop bolt on the floor. Set the carburetor throttle lever to the wide open throttle position, adjust the cable housing assembly to remove any slack and tighten the accelerator cable bracket clip.
4. Loosen the screw retaining the hand throttle cable to the hand throttle lever, located on the accelerator shaft assembly throttle shaft (bellcrank) assembly. Check the hand throttle cable housing to retaining clip for the specified clearance. Loosen the clip and adjust the cable, if required. Tighten the clip screw.
5. With the hand throttle knob on the instrument panel fully depressed and the accelerator shaft assembly in the closed position, insert a feeler gauge of the specified thickness (idle clearance) between the accelerator shaft assembly and the hand throttle lever on the shaft. With the hand throttle cable in the hand throttle lever clevis, feeler gauge in position and the slack removed from the hand throttle cable; tighten the hand throttle cable to hand throttle lever retaining screw.
6. Remove the feeler gauge, start the engine and check the clearance adjustment with the engine operating at idle speed. Operate the accelerator to check for binds or improper operation.

F-AND B-500 THRU 750 SERIES WITH 330, 361 AND 391 V-8

MANUAL TRANSMISSION

Refer to Fig. 10.

1. Adjust the engine idle (hot engine) speed and fuel mixture to specification (refer to appropriate carburetor Part of this Group) and turn off the engine.
2. Adjust the control rod assembly so that the pedal is against the pedal stop bolt with the carburetor throttle plate fully closed.
3. Start the engine and operate the accelerator to check for binds or improper operation.

L-, LT-, LTS-, LN-800, LNT-800 AND LN-500-750 SERIES WITH 330, 361 AND 391 V-8

MANUAL TRANSMISSION

Refer to Fig. 11.

1. Adjust the engine idle (hot engine) speed and fuel mixture to specification (refer to appropriate carburetor Part of this Group) and turn off the engine.
2. Adjust the control rod assembly so that the pedal is against the pedal stop bolt with the carburetor throttle plates fully closed. Be sure the stop bolt is firmly bottomed.
3. Start the engine and operate the accelerator to check for binds or improper operation.

AUTOMATIC TRANSMISSION

Refer to Figure 12 for instructions on adjusting the automatic transmission throttle linkage.

L-, LT-, LTS-, LN-, LNT-900 SERIES WITH 401, 477 AND 534 SD V-8

MANUAL TRANSMISSION

Refer to Fig. 13.

1. Adjust the engine idle (hot engine) speed and fuel mixture to specification (refer to appropriate carburetor Part of this group) and turn off the engine.
2. Adjust the control rod assembly so that the accelerator pedal is against the pedal stop bolt with the carburetor throttle plates fully closed. Be sure the stop bolt is firmly bottomed.
3. Start the engine and operate the accelerator to check for binds or improper operation.

AUTOMATIC TRANSMISSION

Refer to Fig. 14 for instructions on adjusting the automatic transmission throttle linkage.

C-AND CT-SERIES WITH 401, 477 AND 534 SD V-8

MANUAL TRANSMISSION

Refer to Fig. 15 for instructions on adjusting the manual transmission throttle linkage.

AUTOMATIC TRANSMISSION

Refer to Fig. 16 for instructions on adjusting automatic transmission throttle linkage.

CT-800 AND C-500 THRU 800 SERIES WITH 330 HD SIX AND 330, 361 AND 391 V-8

MANUAL TRANSMISSION

Refer to Fig. 17 for instructions on adjusting throttle linkage.

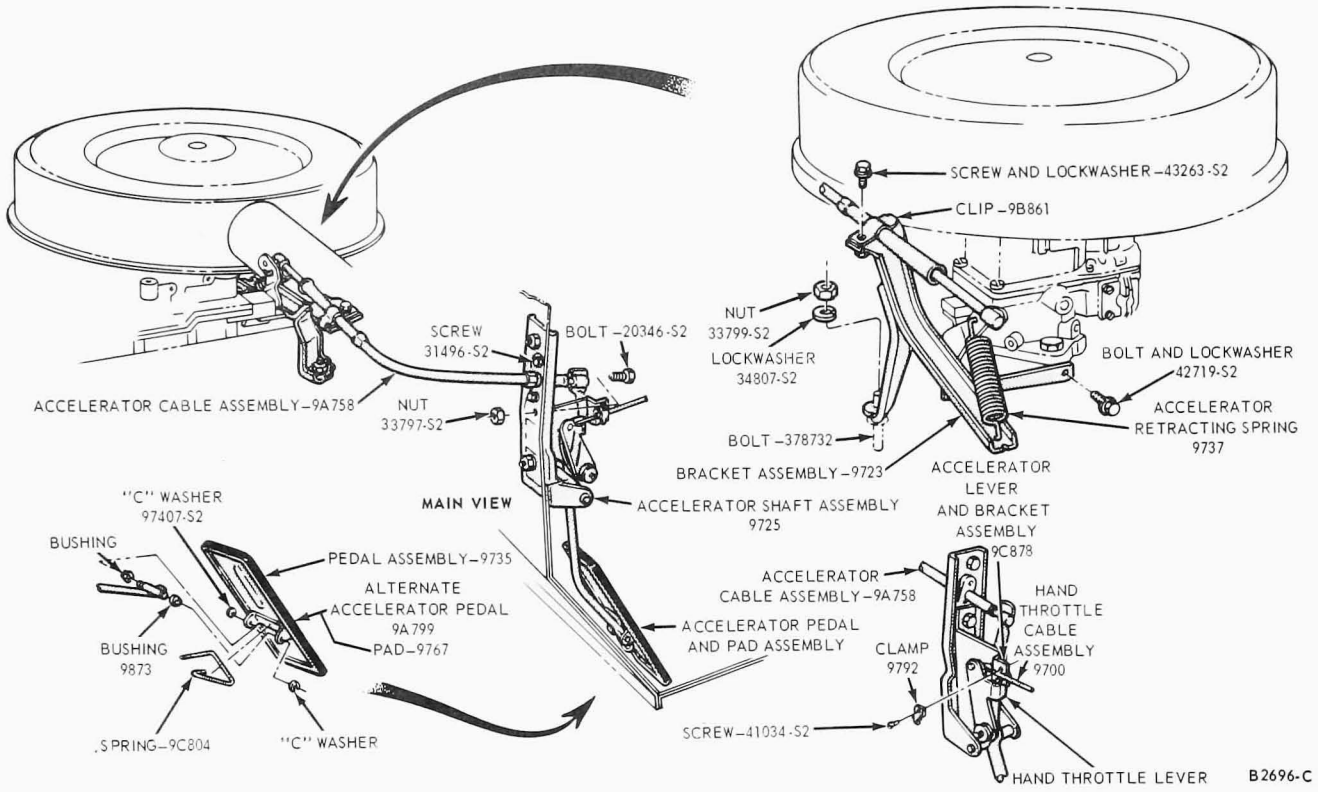

FIG. 1 Throttle Linkage—Bronco 200 Six

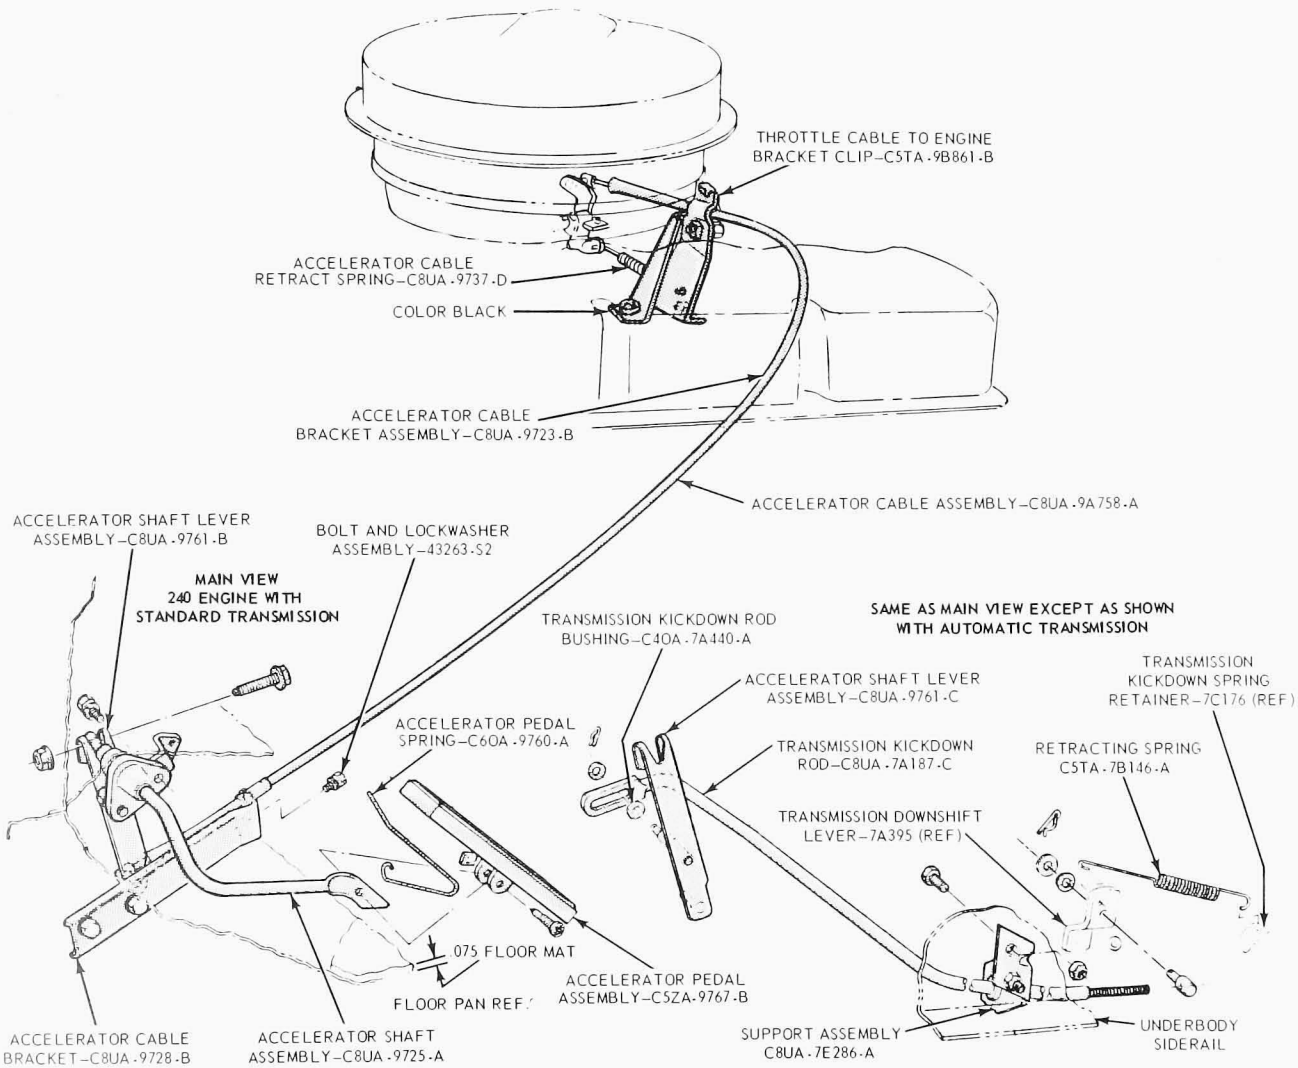

ACCELERATOR ADJUSTMENT PROCEDURE

1. DEPRESS ACCELERATOR PEDAL TO FLOOR
2. LOOSEN CLAMP SCREW, SLIDE CABLE IN BRACKET UNTIL CARBURETOR THROTTLE LEVER IS POSITIONED AGAINST WIDE OPEN STOP
3. TIGHTEN CLAMP SCREW UNTIL CABLE IS HELD SECURELY.

AUTOMATIC TRANSMISSION KICKDOWN LINKAGE ADJUSTMENT

1. AFTER ABOVE ACCELERATION ADJUSTMENT DEPRESS ACCELERATOR TO WIDE OPEN THROTTLE
2. MOVE KICK-DOWN ROD TO ITS MAXIMUM REARWARD POSITION
3. MOVE TRANSMISSION KICK-DOWN CONTROL LEVER TO ITS MAXIMUM FORWARD POSITION
4. TURN TRUNNION ON ROD UNTIL IT ALIGNS WITH HOLE IN LEVER, THEN LENGTHEN 1 TO 2 TURNS
5. ASSEMBLE TO TRANSMISSION DOWNSHIFT LEVER.

INSTALLATION & ADJUSTMENT PROCEDURE

1. WITH THE TRANSMISSION IN DRIVE AND THE ENGINE AT NORMAL OPERATING TEMPERATURE, ADJUST CARBURETOR SETTING TO OBTAIN ENGINE IDLE SPECIFIED.
   NOTE: ENGINE MUST NOT BE RUNNING WHILE ADJUSTING STEPS 2, 3, & 4 ARE MADE.
2. INSERT A .245-.250 DIA. PIN THRU LOCKING HOLES "A".
3. ADJUST STOP 'H' TO CONTACT ROD 'C'.
4. ADJUST ROD 'C' TO LENGTH WITH CARBURETOR LEVER AT IDLE POSITION.
5. PLACE LEVER "D" IN EXTREME REARWARD POSITION AND INSTALL ROD "E". SHORTEN ROD "E" BY THREE (3) TURNS.
6. REMOVE LOCKING PIN. HOLD ACCELERATOR PEDAL AGAINST STOP AND ADJUST ROD 'B' UNTIL LEVER 'D' IS ROTATED BACK AGAINST THE FULL KICK DOWN STOP.
7. ADJUST DETENT STOP 'G' TO JUST CONTACT THE ACCELERATOR PEDAL WHEN CARBURETOR THROTTLE LEVER IS IN WIDE-OPEN POSITION.
8. CHECK SHIFT POINTS AND DOWNSHIFT. IF FULL THROTTLE (AT DETENT) UPSHIFT DOES NOT OCCUR BETWEEN THE FOLLOWING ENGINE R.P.M.
   3525 TO 3575 FOR 401 CU. IN. ENG.
   3325 TO 3375 FOR 477 CU. IN. ENG.
   3125 TO 3175 FOR 534 CU. IN. ENG.
   IT WILL BE NECESSARY TO RE-ADJUST THE ROD ASSEMBLY E AS FOLLOWS:
   TO RAISE SHIFT POINT R.P.M. SHORTEN ROD ASSEMBLY
   TO LOWER SHIFT POINT R.P.M. LENGTHEN ROD ASSEMBLY

V 1327-B

FIG. 13 Throttle Linkage L, LT, LTS-900 with 401, 477, 534 SD V-8 with Transmatic

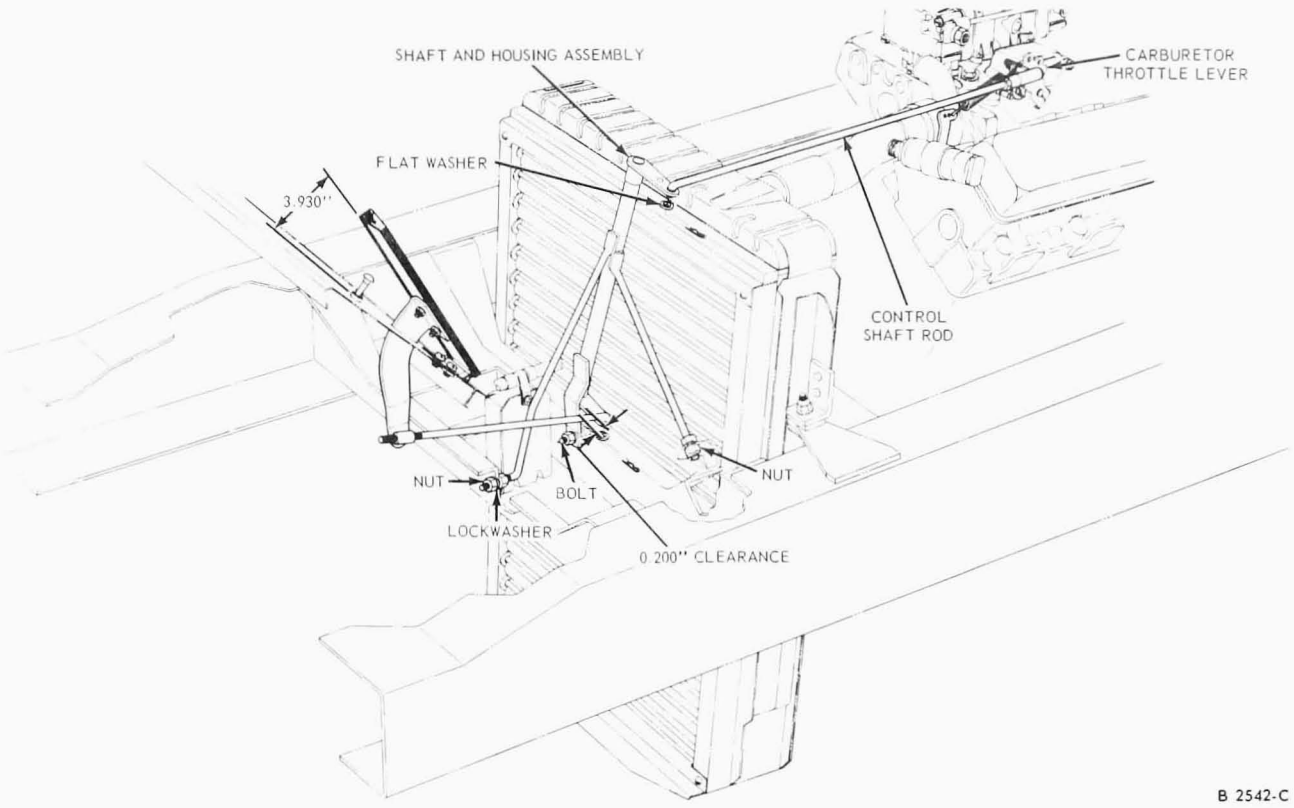

FIG. 14 Throttle Linkage—C and CT-Series with 401, 477 and 534 SD V-8

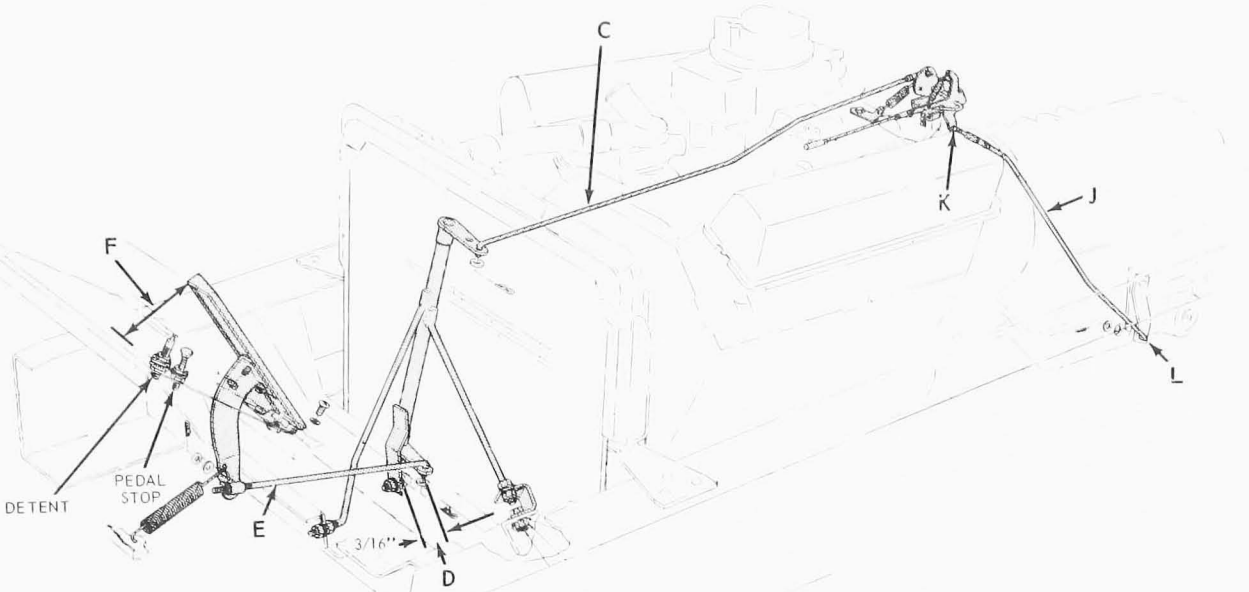

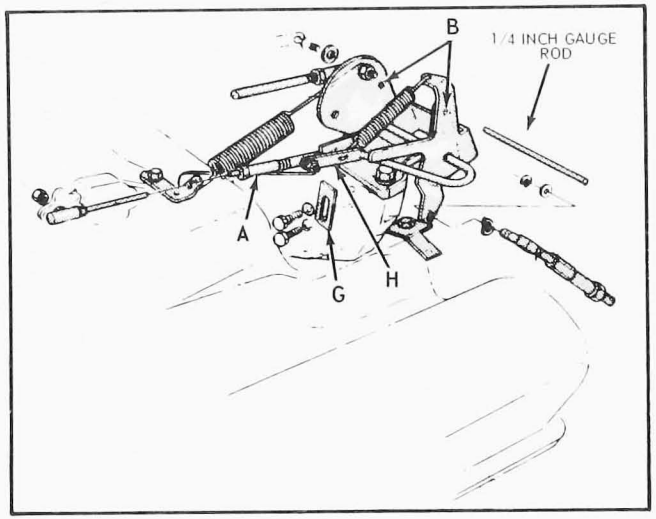

1. ADJUST ENGINE IDLE SPEED TO SPECIFICATION STOP ENGINE.
2. ADJUST ROD A UNTIL A 1/4-INCH GAUGE PIN CAN BE INSERTED AT B.
3. ADJUST ROD C UNTIL A 3/16-INCH CLEARANCE IS OBTAINED AT POINT D.
4. ADJUST ROD E UNTIL A 4-INCH CLEARANCE IS OBTAINED AT POINT F.
5. ADJUST THE STOP G UNTIL IT TOUCHES SHAFT H.
6. DISCONNECT ROD J AT POINT K AND PUSH DOWNWARD UNTIL LEVER L IS AGAINST THE INTERNAL TRANSMISSION STOP. ADJUST THE ROD UNTIL IT FREELY ENTERS THE PIVOT AT POINT K. SHORTEN THE ROD BY TURNING THE ADJUSTING SLEEVE CLOCKWISE 3 TURNS. RE-CONNECT ROD J AND REMOVE GAUGE PIN.
7. ADJUST ACCELERATOR PEDAL DETENT STOP TO JUST MAKE CONTACT WITH THE ACCELERATOR PEDAL WHEN CARBURETOR THROTTLE LEVER CONTACTS THE FULL THROTTLE STOP ON THE CARBURETOR.
8. DEPRESS THE ACCELERATOR PEDAL COMPLETELY UNTIL THE TRANSMISSION CONTROL ROD J IS AT MAXIMUM UPWARD TRAVEL. ADJUST THE ACCELERATOR PEDAL STOP TO JUST CONTACT THE UNDERSIDE OF THE PEDAL.
9. IF THE THROTTLE (AT DETENT) UPSHIFT DOES NOT OCCUR WITHIN SPECIFICATIONS, RE-ADJUST THE CONTROL ROD J. SHORTEN THE ROD TO INCREASE SHIFT RPM; LENGTHEN TO DECREASE SHIFT RPM.

COMPONENT INDEX	Page	COMPONENT INDEX	Page
FUEL SYSTEM		IDLE SPEED ADJUSTMENTS	
Description	02-01	High and Low Idle Adjustments	02-01

DESCRIPTION

A schematic diagram of the Ford V-8 Series Diesel Engine is shown in Figure 1.

A mechanically operated diaphragm type transfer pump is used to draw fuel from the supply tank to the multi-plunger injection pump. The transfer pump is mounted directly to the side of the fuel injection pump housing and is actuated by an arm riding on an eccentric on the camshaft. A two-stage fuel filter is placed on the pressure side of the transfer pump. Since the filter is located on the pressure side of the transfer pump the possibility of air induction into the fuel system is eliminated.

From the fuel filter the fuel travels through the engine shut-off solenoid to the multi-plunger injection pump. Eight individual barrel and plunger type fuel injection pumps meter and pressurize the fuel. The pressurized fuel then travels through high pressure lines to its respective cylinder injector where it is injected.

The injectors are of the direct injection type. They spray atomized fuel into each cylinder and seal against fuel drip. All injectors are interconnected by an excess fuel return line system which carries all unused fuel back to the supply tank.

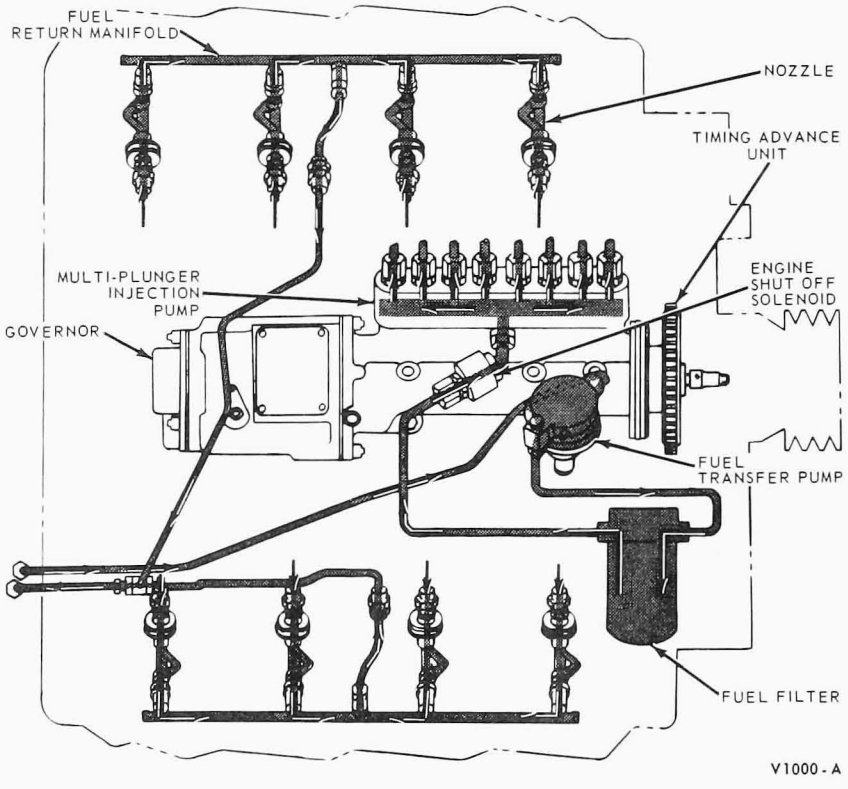

FIG. 1 Ford V-8 Series Diesel Engine Fuel System

ADJUSTMENTS

IDLE SPEED ADJUSTMENT

Check the engine high (governed no-load) rpm and low idle rpm per the chart shown in Fig. 2. Use of a direct reading tachometer is recommended.

If the high idle or low idle rpm is not to specifications, free up or adjust the throttle linkage before making any adjustment of the governor settings. The idle settings, both high and low, are adjusted at the factory and any deviation from specifications should be due to the throttle linkage assembly or operation.

If throttle linkage adjustment will not correct the idle speeds to specifications, follow the procedure given below to adjust both high and low idle. **Only qualified personnel should perform this operation.**

HIGH AND LOW IDLE RPM

Check the engine rpm with an accurate tachometer. Install the tachometer on the adapter located on

the front cover (Fig. 3). The reading taken at this point, with a 1:1 tachometer, will be one-half engine rpm.

Remove the high idle adjustment screw cover from the rear of the governor. Turn the high idle adjusting screw (Figs. 4 and 5) clockwise to increase or counterclockwise to decrease high idle speed. **If the adjusting screw requires alignment to install the cover, turn the screw in a clockwise direction the minimum distance required for installation.**

Adjust low idle speed by loosening lock nut (Fig. 4) and turning the adjustable stop. Turning the stop IN decreases and OUT increases the low idle speed. Tighten the lock nut and recheck the adjustment.

Model	ENGINE SPEED – RPM		
	High Idle	Full Load	Low Idle (+0, –10 RPM)
150 HP	3380	3200	525
175 HP	3450	3200	525
200 HP	3320	3000	525
225 HP	3080	2800	525

DESCRIPTION

This part provides information for in-vehicle service of Ford Diesel Trucks euipped with Cummins NH Series Diesel engines.

Overhaul procedures, replacement procedures, test stand procedures, specifications and wear limits are covered in **the Cummins H and NH Engine shop Manual and the Truck and Bus Diesels Maintenance Manual.**

FUEL SYSTEM

The PT fuel system delivers fuel to each cylinder of the engine in equal, predetermined amounts. Thus PT is an abbreviation for pressure-time. The fuel system consists of the supply tank(s), fuel filter, fuel pump, governor, injectors, fuel shutoff valve, and the fuel supply and drain lines (Figs. 1 and 2).

The fuel pump is coupled to the air compressor which is driven from the engine gear train. The fuel pump main shaft turns at engine crankshaft speed, and drives the gear pump, governor and tachometer shaft.

The fuel pump consists of a gear pump which draws fuel from the supply tank and delivers it to the injectors under pressure, and a governor and throttle which controls fuel pressure to the injectors. A pulsation damper prolongs gear pump life. It smoothes the flow of fuel through the pump.

The gear pump receives fuel from the supply tank and pumps the fuel under pressure, varying with engine speed, through the filter screen and governor to the throttle and to the injectors. The filter screen, mounted in the top of the fuel pump, prevents damage to the fuel pump and injectors by filtering from the fuel any foreign particles that may be present. To provide fuel pump cooling a small amount of fuel is bled from the fuel pump and returned to the fuel tank. Thus, a circulation of cooling fuel is provided.

At idle speed, the main throttle shaft passage is closed, allowing fuel flow around the throttle shaft to the idle port in the governor barrel. At engine speeds above idle, the fuel flows through the main throttle shaft hole and enters the main fuel port in the governor barrel.

When the throttle lever is moved to the idle position and the vehicle is moving in excess of idle speed, a small amount of throttle leakage is provided to purge the injectors of air. The PT fuel pump governor controls both idle and high speed. On the NH-Series engines, the fuel manifold is a tube mounted externally on the engine, with equal length branches (tubing) to the injectors. On the NHC, NHCT and NTC engines, the manifolds are drilled passages, one in each cylinder head, which are each aligned with an annulus in the injector body. These fuel manifolds are connected to the pressure side of the fuel pump by a common fuel line.

Fuel circulates through the injector at all times, except for a short period following injection into the cylinder. From the inlet, fuel flows down the inlet passage of the injector, around the injector plunger, between the body end and cup, up the drain passage to the drain connections and manifold and back to the supply tank.

As the plunger comes up, the injector feed passage is opened and fuel flows through the metering orifice into the cup. At the same time, fuel flows past the cup and out the drain orifice. The amount of fuel which enters the cup is controlled by the fuel pressure against the metering orifice. Fuel pressure is controlled by the fuel pump.

The plunger, during injection, comes down until the metering orifice is closed and the fuel in the cup is injected

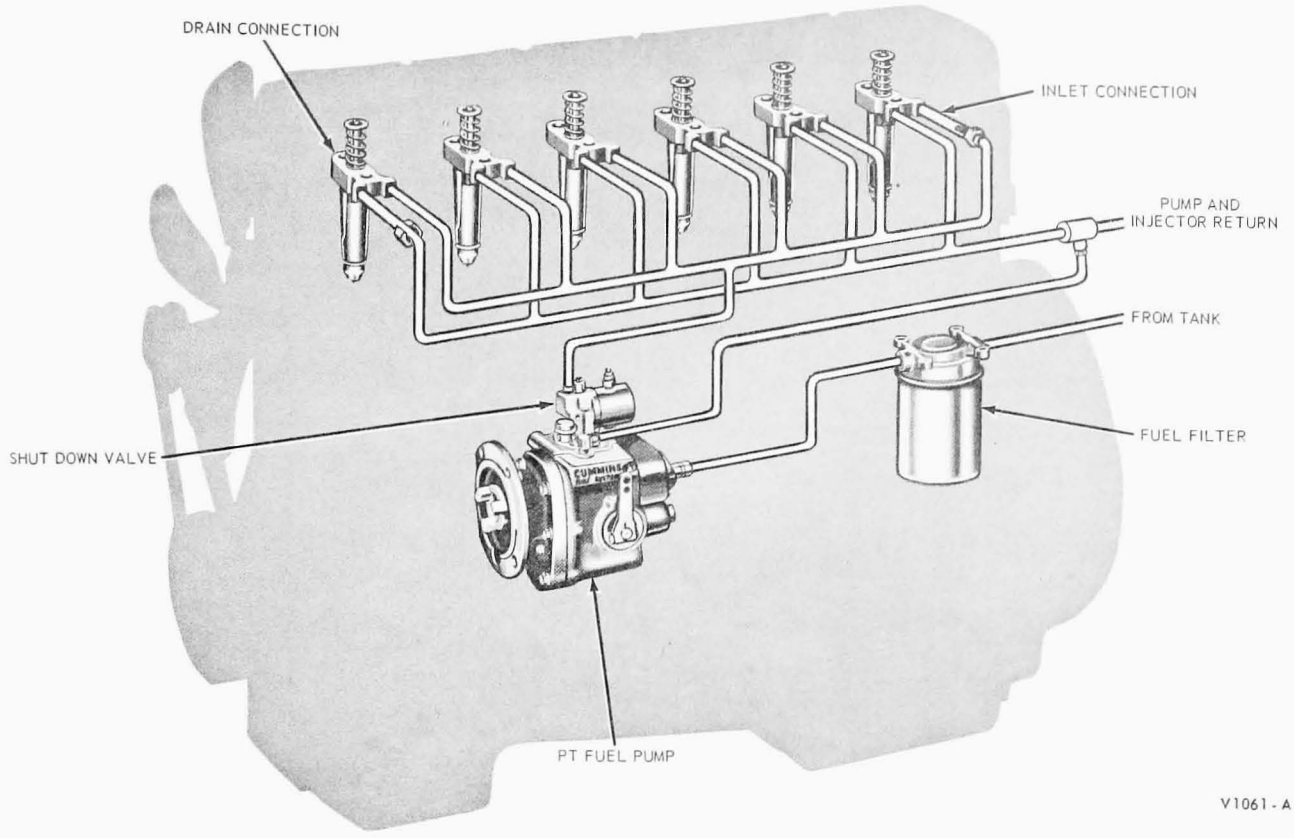

FIG. 1 NH-Series Engine Fuel System

into the cylinder. While the plunger is seated in the cup, all fuel flow in the injector is stopped.

On the NH-Series engines a flanged injector (Fig. 3) is used. The fuel manifold is connected to the inlet port of the injector flange. A removable inlet screen is installed in each inlet port for final fuel filtration. The drain port is located adjacent to the inlet port. The drain ports are connected by a drain manifold to return surplus fuel to the supply tank.

The NHC, NHCT and NTC engines utilize a cylindrical injector (Fig. 3). Two radial grooves (annuli) on the injector body index with two drilled passages in each cylinder head, which serve as fuel inlet and drain manifolds. The inlet annulus contains a fine mesh screen for final fuel filtration. A fuel crossover drain tube, at the flywheel end of the engine, connects the two cylinder head drain passages and a common line returns the unused fuel to the fuel tank.

The fuel grooves around the cylindrical injectors are separated by O-rings which seal against the cylinder head injector bore forming a leak proof passage between the injectors and the cylinder head injector bore surface. The injectors contain an orifice plug which

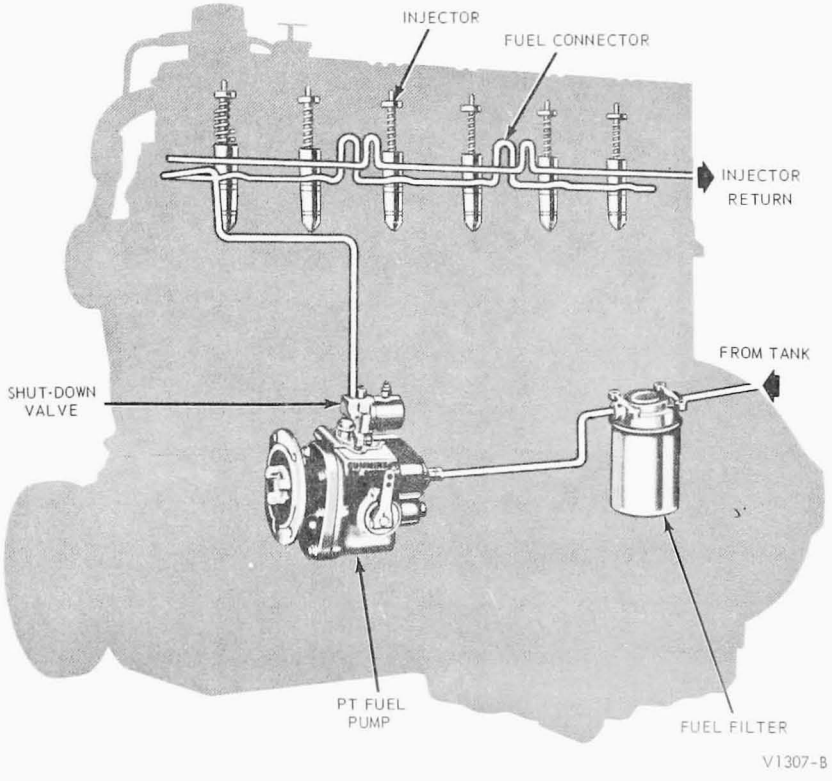

FIG. 2 NHC, NHCT and NTC-Series Engine Fuel System

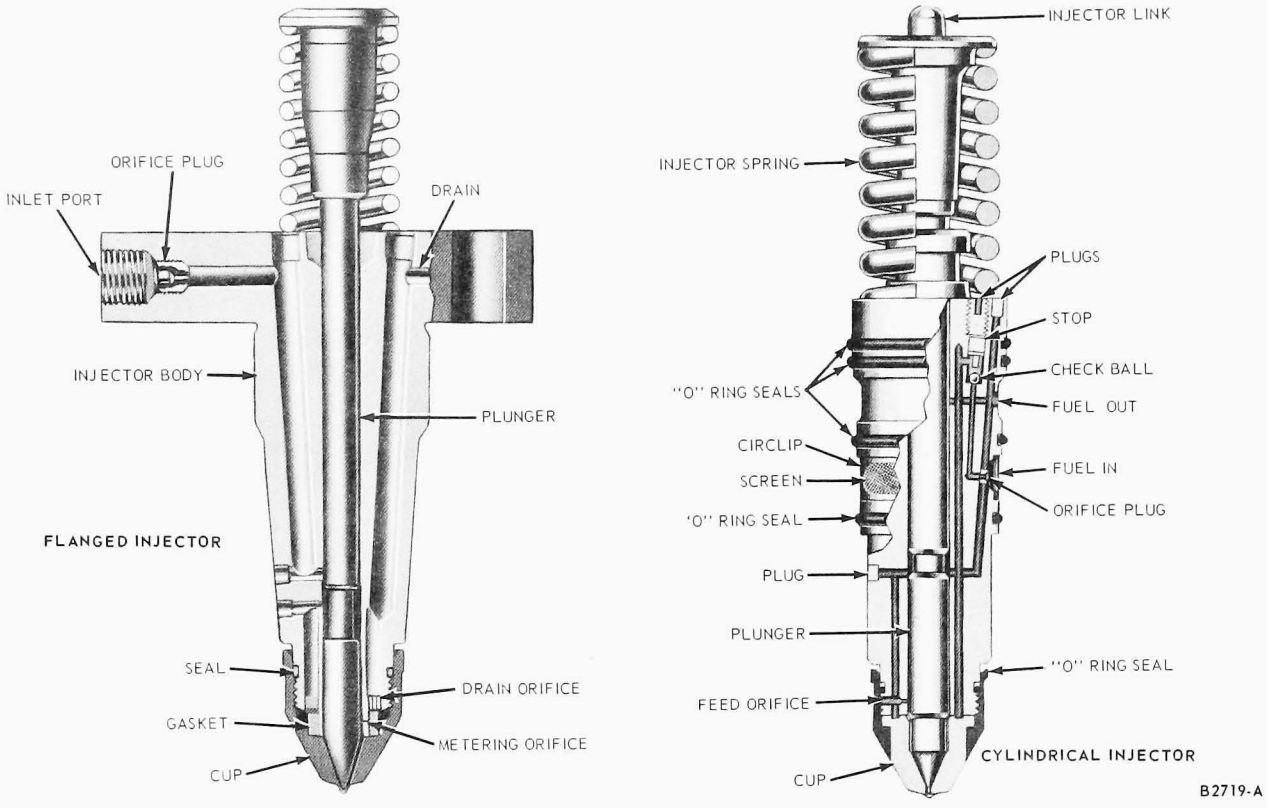

FIG. 3 Flanged and Cylindrical Injector

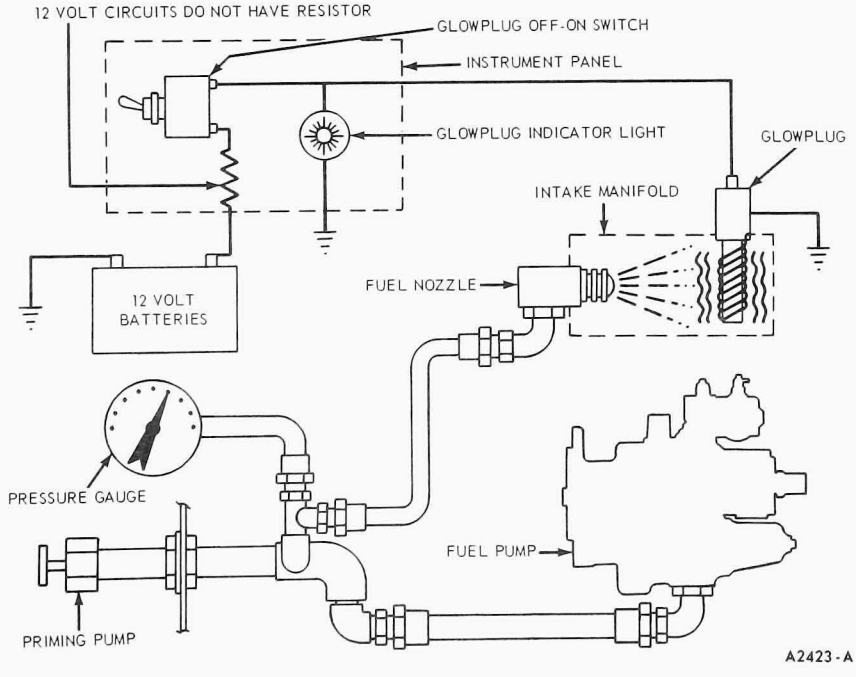

FIG. 4 Preheater Operation

can be varied in inside diameter to achieve identical fuel delivery through all injectors.

COLD STARTING SYSTEMS

To assist in cold weather starting, various systems are available. The preheater consists of a glow plug which is electrically heated by the battery and a hand priming pump which sprays fuel into the intake manifold. The fuel burning in the manifold heats the intake air. Fig. 4 shows the preheater operation. **Never use ether when using the preheater.**

Another cold weather starting aid is the ether quick-start, measured-shot system. This system consists of an ether tank and a manually controlled metering valve or quick start choke to inject shots of ether into the intake manifold. A typical installation is shown in Fig. 5.

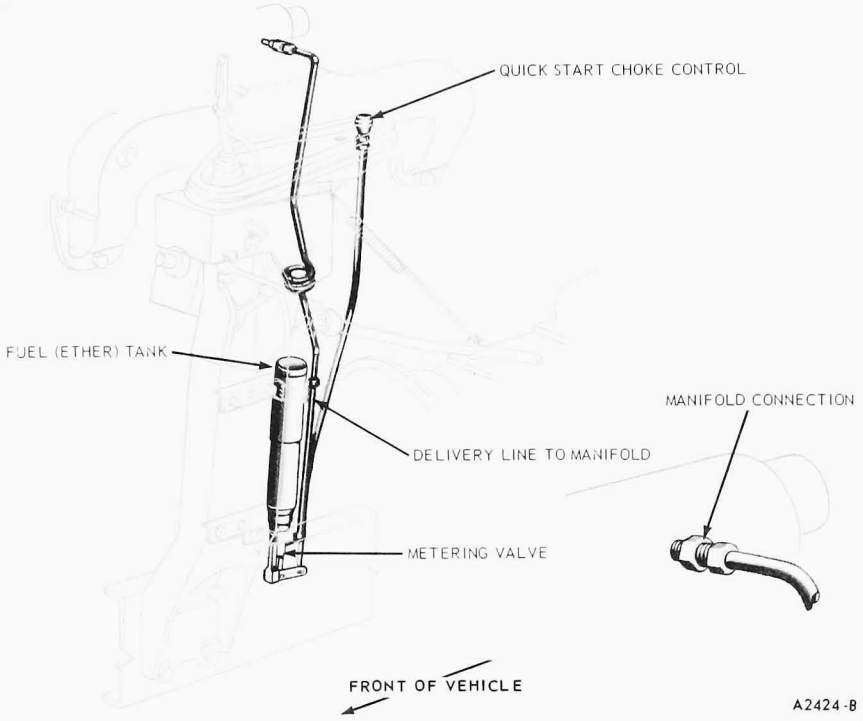

FIG. 5 Ether Quick Start Unit

ADJUSTMENTS

FUEL PUMP ADJUSTMENT

Only those fuel pump adjustments described herein should be performed in the truck. Make the adjustments in the order given.

In-chassis adjustments of the fuel pump are based on fuel manifold pressure and fuel supply vacuum.

The following adjustment procedures should be performed before adjusting the forward throttle screw and rear throttle screw. The forward throttle screw is closer to the drive end of the fuel pump (Fig. 6).

1. Operate the engine until the oil temperature reaches 140 to 160 degrees F. Make all fuel pump or injector settings on a hot engine.
2. Determine the fuel manifold pressure and fuel supply pressure by snap reading which provides a method of finding maximum fuel manifold pressure and fuel supply vacuum without a dynamometer. Obtain manifold pressure and fuel supply vacuum readings when the engine is at full load and rated speed. **When the engine is accelerated to full throttle, full engine load is**

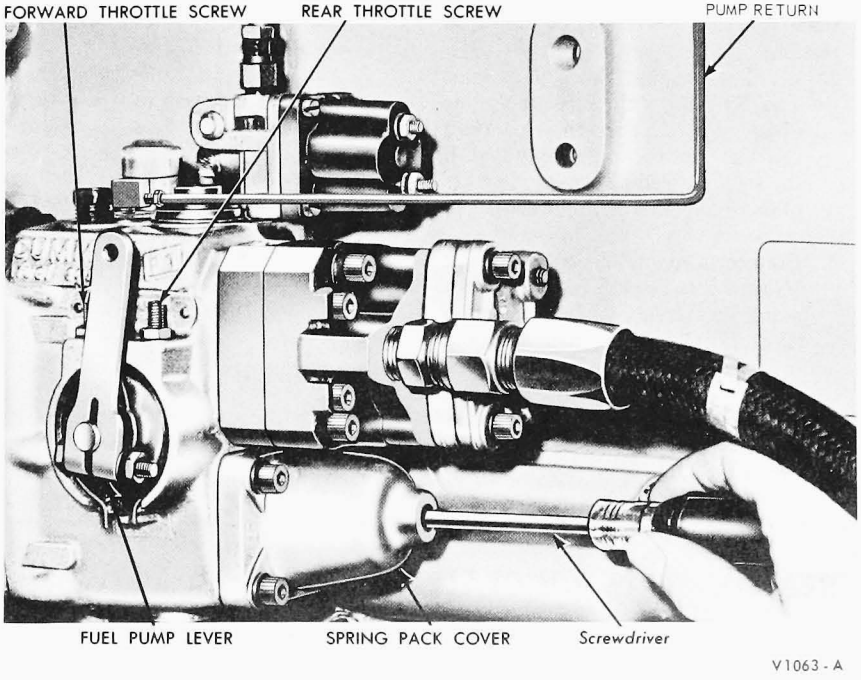

FIG. 6 Fuel Pump Adjustments

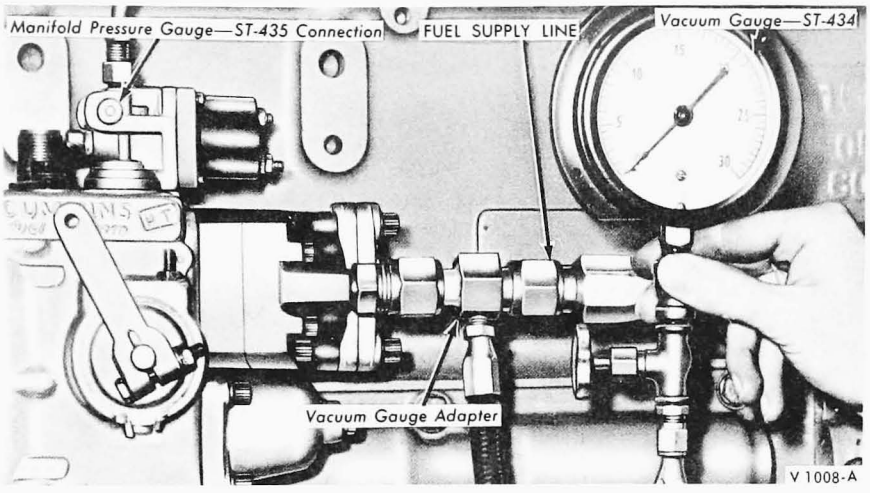

FIG. 7 Fuel Pump Gauge Connections

momentarily attained when the engine reaches rated speed. Fuel pressure and vacuum gauge readings increase with engine speed until rated speed is reached. At this point the gauge hand hesitates and falls off due to governor action at speeds above rated speed. It is necessary to read the maximum swing of the pressure gauge hand quickly. The snap reading technique is not as accurate as measurements obtained with a dynamometer.

Snap reading gives an indication of fuel manifold pressure and fuel supply vacuum. **For a more dependable reading, use the average of five snap readings.**

3. Install a vacuum gauge (Cummins Tool ST-434) in the fuel supply line (Fig. 7). Check the suction restriction of the fuel supply line. If the vacuum reading exceeds 8 inches of mercury, determine the cause and correct.
4. Connect a manifold pressure gauge (Cummins Tool ST-435) at the manifold pressure gauge connection (Fig. 7). Check the fuel manifold pressure at rated speed and full load. If the manifold pressure is not within specifications, correct as necessary.
5. Adjust valve and injector lash to specifications.
6. Check high-idle or maximum governed speed.

REAR THROTTLE SCREW ADJUSTMENT

1. Connect a manifold pressure gauge (Cummins ST-435) at the manifold pressure gauge connection (Fig. 7). Check the fuel manifold pressure at rated speed and full load.
2. Turn the rear throttle screw out until the highest fuel manifold pressure reading is obtained.
3. Turn the rear throttle screw in to reduce the fuel manifold pressure 5 psi.

Do not increase the rear throttle adjustment more than 5 psi or the engine speed at which peak torque occurs will change. Throttle restriction over 5 psi allows unauthorized adjustment to raise fuel manifold pressure, thereby overfueling the engine.

THROTTLE LEAKAGE ADJUSTMENT

1. With the engine operating at idle speed, turn in the forward throttle screw until the engine gains speed. Back the screw out two full turns.
2. Stop the engine and remove the spring pack cover plug and adjust the idle governor screw (Fig. 6) to idle the engine at specified rpm (see specifications).
3. Operate the engine until it is purged of the air let in during step 2.
4. Check the idle speed.
5. Check deceleration; if it is too slow, the throttle leakage is excessive. If the engine falters or dies when idle speed is reached, the throttle leakage is too low. Adjust the screw to obtain permissible deceleration time.
6. Any change in the desired idle speed is made with the governor idle screw. Follow the sequence under Idle Speed Adjustments.

IDLE SPEED ADJUSTMENTS

1. With the engine stopped, remove the pipe plug from the spring pack cover.
2. The idle adjustment screw is held in position with a spring clip. Turn the screw in to increase or out to decrease the speed (Fig. 6).
3. Replace the pipe plug. With the engine running, air which collected in the spring pack housing will cause a rough idle temporarily. This will stabilize when the housing fills with fuel.

INJECTOR TIMING

Refer to Engine timing in the Cummins H-and NH-Engine Shop Manual.

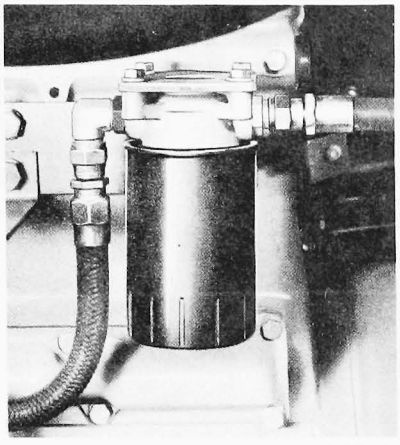
INJECTOR ADJUSTMENT

Refer to Injector and Valve Adjustment in the Cummins H-and NH-Engine Shop Manual.

REMOVAL AND INSTALLATION

FUEL FILTER ELEMENT

The fuel filter (Fig. 8) has a disposable-type element. Replace it at the specified interval, even though it may appear serviceable. Unscrew the combination filter case and element and discard it. Install the new filter case and element assembly and tighten it by hand until the O-ring seal touches the filter head. Then tighten it an additional 1/4 to 1/2 turn by hand. **If the replacement filter does not have an integral O-ring seal, use a new O-ring for installation.**



V1065-A

FIG. 8 Typical Engine Mounted Fuel Filter

FUEL PUMP SCREEN

Removal

1. Remove the retainer cap from the fuel pump. Remove the spring and lift out the filter screen assembly (Fig. 9).
2. Remove the top screen retainer from the filter screen assembly. Wash the screen and magnet in cleaning solvent and dry with compressed air. Install the top screen retainer.

Installation

1. Install the filter screen, **with the hole down,** in the fuel pump.
2. Install the spring and retainer cap. Torque the retainer cap to specifications.

FUEL PUMP ASSEMBLY

Removal

1. Disconnect the accelerator return spring. Disconnect the hand throttle control, tachometer cable and accelerator rod at the fuel pump.

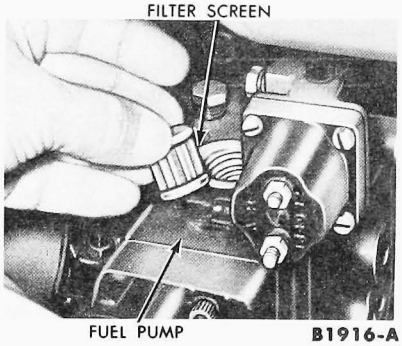


FIG. 9 Removing Fuel Pump Filter Screen

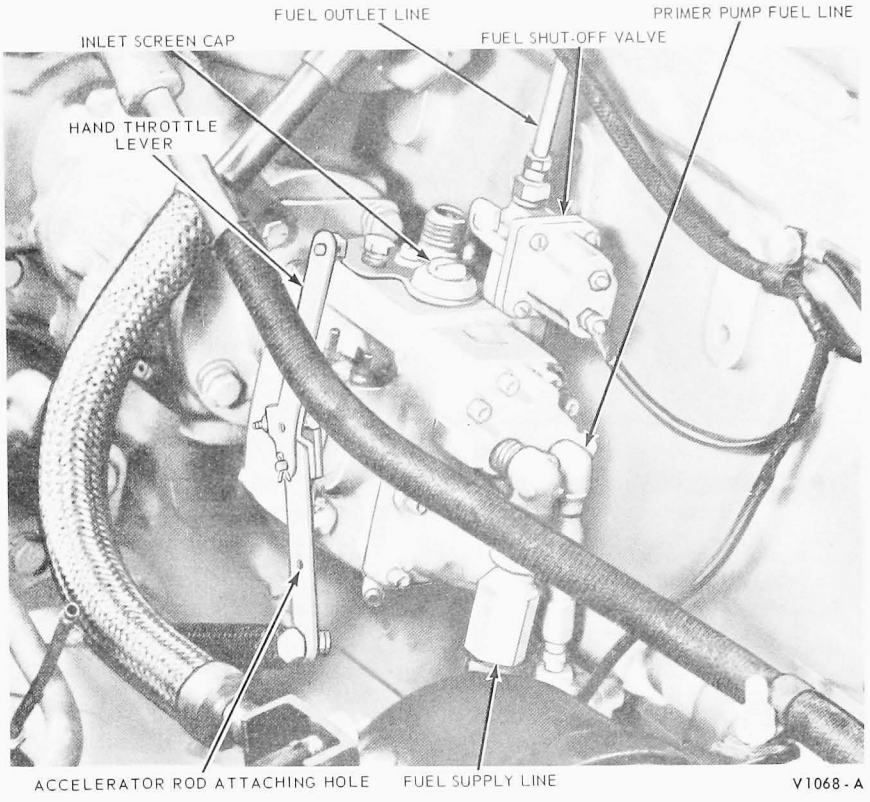

FIG. 10 Typical Fuel Pump Installation

Disconnect the lead to the fuel shut-off valve.

2. Disconnect the primer fuel pump line and fuel supply line at the fuel pump (Fig. 10). Remove the fuel outlet line from the shut-off valve and fuel manifold. Disconnect the fuel bleed line.
3. Remove the fuel pump mounting bolts. Remove the fuel pump, gasket and pump drive rubber buffer.

Installation

1. Clean the gasket surfaces of the fuel pump and air compressor.
2. Install the pump drive rubber buffer. Position a new fuel pump gasket on the air compressor and install the fuel pump. Torque the mounting bolts to specifications.
3. Connect the primer fuel pump line and fuel supply line to the fuel pump (Fig. 10). Connect the fuel outlet line to the fuel manifold and fuel shut-off valve. Connect the fuel bleed line.
4. Connect the accelerator rod, hand throttle control and tachometer cable to the fuel pump. Connect the fuel shut-off valve lead. Connect the accelerator return spring.
5. Check the accelerator linkage and adjust if necessary.
6. Start the engine and check for leaks.

FUEL INJECTORS

NH-SERIES ENGINES

Removal

1. Refer to Part 22-03, Rocker Housing Cover Removal, and remove the rocker housing cover(s).
2. Disconnect the fuel manifold and fuel return line from the injector inlet and drain connections. Remove the fuel inlet screen (Fig. 11). Remove the fuel inlet and drain connections from the injector (Fig. 12).
3. Loosen the injector rocker lever lock nut and unscrew the adjusting screw until the push rod can be disengaged. Disengage the push rod and tip the rocker lever away from the injector.
4. Remove the injector retaining screws and lift the injector from the cylinder head. **Do not bruise the injector tip. Do not turn the injector bottom side up or the plunger will fall out. Leave the plunger in the injector as the plungers are not interchangeable.**

Installation

1. Insert the injector in the cylinder head. **Be sure the plunger is positioned with the plunger class**

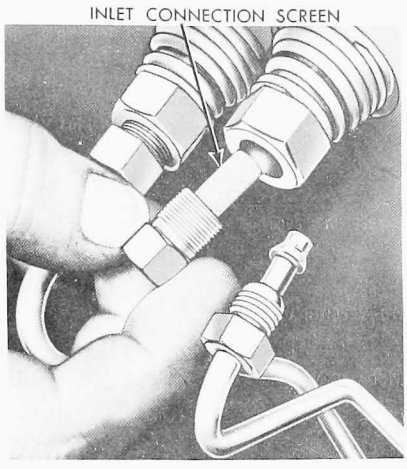

FIG. 11 Removing Injector Inlet Screen

mark centered between the inlet and drain connections.

2. Lubricate the retaining screw threads. Start, **but do not tighten,** the retaining screws. Align the injector by installing the inlet and drain connections 2 turns in the injector (Fig. 12). Torque the retaining screws alternately to specifications.
3. Torque the inlet and drain connections to specifications. Install

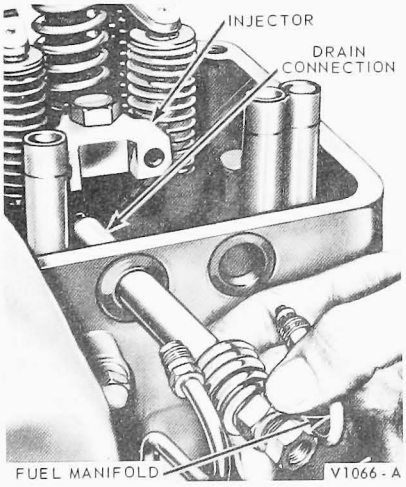

FIG. 12 Injector Fuel Inlet and Drain Connections

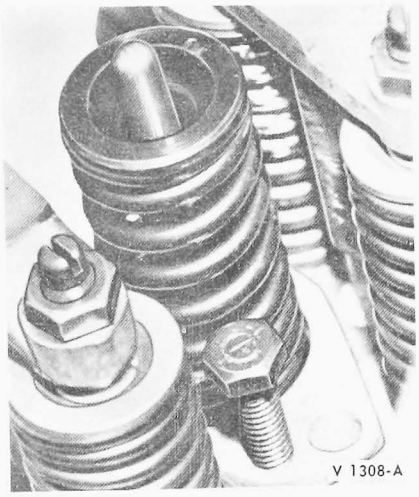

FIG. 13 Removing Cylindrical Injector

the fuel inlet screen (Fig. 13) and connect the fuel manifold and fuel return line.

4. Position the push rod under the rocker lever and adjust the injector rocker lever lash to specifications.
5. Refer to Part 22-03, Rocker Housing Cover Installation, and install the rocker housing cover(s). Partially tighten the cover screws.
6. Operate the engine until the oil temperature is 140 degrees F and adjust the injector lash to specifications.

NHC, NHCT AND NTC ENGINES

Removal

1. Refer to Part 22-03, Rocker Housing Removal and remove the rocker housing cover.
2. Remove capscrews from the injector hold down plate.
3. Loosen the lock nut and backoff the injector rocker lever adjusting screw until the push rod can be disengaged. Hold the push rod aside and tip the rocker lever away from the injector to clear the injector link.
4. Insert one capscrew in the tapped hole in the injector hold down plate and jack the injector from the head (Fig. 13). Remove the O-rings.

Avoid bruising the injector tip. do not turn the injector upside down as the plunger might fall out. Injector plungers are not interchangeable.

Installation

1. Clean the injector sleeve with cloth wrapped around a wooden stick.
2. Lubricate the injector body O-rings with Lubriplate. Lubricating oil or fuel oil is not adequate. **The O-rings should receive a fresh coat of Lubriplate each time the injectors are installed in the head.**
3. Start the injector into bore; guide by hand until injector is aligned in bore and not binding in any manner. **When installing injector from intake side of engine, injectors are to be placed with ball check retainer plug at one o'clock.**
4. Place a hammer handle butt on top of injector plunger guide, and **seat injector by giving a quick hard push on the hammer. A snap** should be heard and felt as the cup seats in the copper sleeve.
5. Place the hold-down plate over the injector body with the counterbore up; position half-collet locking clamps in injector body groove. Start the hold-down capscrews. **Do not tighten.**
6. With clamps centered, place injector spring on hold-down plate with closed end down. **Spring must seat on hold-down plate. If spring sits on locking clamps, incorrect injector adjustment will result causing push rod lobe and camshaft damage.**
7. Holding the injector spring in position, carefully insert the injector plunger. **Position plunger in injector bore with class mark on the plunger (midway between inlet and drain ports of injector). This will provide the same operating position in which the injector was calibrated.**
8. Torque the hold-down capscrews in alternate steps to specifications.
9. Position the injector rocker lever on the injector push tube.
10. Adjust the injectors and valves.
11. Install the rocker housing cover following procedures under Rocker Housing Installation in Part 22-03.

SPECIFICATIONS

CUMMINS DIESEL ENGINE ADJUSTMENT SETTINGS AND TORQUE LIMITS

Specifications for overhaul of the fuel system components are included in the Cummins N-NH-Series Engine Overhaul Manuals.	
Injector Installed Position – Cylindrical Injector

CV1155-A

PART 25-04 Detroit Diesel Fuel System

GENERAL INFORMATION

All adjustment, removal and installation and repair operations should be performed by authorized Detroit Diesel Engine Dealers. When Ford Truck Dealer personnel are trained and authorized to service Detroit Diesel engines, they may perform adjustment and repair operations.

Ford truck dealers may do minor maintenance operations on Detroit Diesel engines such as change fuel filter and fuel strainer elements and adjust accelerator linkage (Part 25-60).

A schematic diagram of the Detroit Diesel engine fuel system is shown in Fig. 1. The gear-type fuel pump supplies fuel under pressure to the inlet fuel manifold in each cylinder head. The inlet side of each injector is connected by piping to the fuel manifolds. The needle valve injectors, one for each cylinder, increase the fuel pressure, meter the amount of fuel and inject it into each combustion chamber. A limiting-speed governor controls the metering capacity of the injectors to regulate engine speed.

Surplus fuel, not used by the injector, and fuel used to cool the injector parts is piped to the fuel return manifold and flows back to the supply tank. A restriction in the fuel return line maintains the fuel system pressure.

The fuel strainer and fuel filter (Fig. 2) remove impurities from the fuel. The fuel strainer, located between the fuel pump and supply tank, has a replaceable element of 30 micron capacity. The 10-micron-capacity, replaceable-element fuel filter is incorporated in the fuel system between the fuel pump and fuel inlet manifold.

A drain cock is provided at the bottom of the fuel strainer and fuel filter to facilitate the removal of accumulated sediment and water.

DESCRIPTION

LIFT PUMPS

Ford V-8 Lift Pump

A mechanically operated diaphragm type lift pump is used to draw fuel from the supply tank to the multi-plunger injection pump. The lift pump is mounted directly to the side of the fuel injection pump housing and is actuated by an arm riding on an eccentric on the camshaft. A two-stage fuel filter is placed on the pressure side of the pump. Since the filter is located on the pressure side, the possibility of air induction into the fuel system is eliminated.

Cummins Diesel Lift Pump

The lift pump is coupled to the air compressor which is driven from the engine gear train. The lift pump main shaft turns at engine crankshaft speed, and drives the gear pump, governor and tachometer shaft.

The lift pump consists of a gear pump to draw fuel from the supply tank and deliver it to the injectors under pressure, and a governor and throttle to control fuel pressure to the injectors. A pulsation damper prolongs gear pump life, as it smoothes the flow of fuel through the pump.

The gear pump receives fuel from the supply tank and pumps the fuel under pressure, varying with engine speed, through the filter screen and governor to the throttle and to the injectors. The filter screen, mounted in the top of the lift pump, prevents damage to the pump and injectors by filtering from the fuel any foreign particles that may be present. To provide lift pump cooling a small amount of fuel is bled from the fuel pump and returned to the fuel tank. Thus, a circulation of cooling fuel is provided.

Detroit Diesel Lift Pump

The positive displacement gear type fuel pump transfers the fuel from the fuel tank to the fuel injectors. The pump circulates an excess supply of fuel through the injectors, which purges the air from the system and cools the injectors. The unused portion of the fuel returns to the fuel tank through the fuel return manifold and fuel return line.

The pump is attached to the rear end plate cover of the blower assembly and is driven off the end of the lower blower rotor by a drive coupling fork attached to the end of the pump drive shaft and a drive disc attached to the blower rotor.

ADJUSTMENTS

The only adjustments that can be performed are on the Cummins Diesel lift pump.

LIFT PUMP

Cummins Diesel

Only those fuel pump adjustments described herein should be performed in the truck. Make the adjustments in the order given.

In-chassis adjustments of the fuel pump are based on fuel manifold pressure and fuel supply vacuum.

The following adjustment procedures should be performed before adjusting the forward throttle screw and rear throttle screw. The forward throttle screw is closer to the drive end of the fuel pump (Fig. 1).

1. Operate the engine until the oil temperature reaches 140 degrees to 160 degrees F. Make all fuel pump or injector settings on a hot engine.
2. Determine the fuel manifold pressure and fuel supply pressure by snap reading which provides a method of finding maximum fuel manifold pressure and fuel supply vacuum without a dynamometer. Obtain manifold pressure and fuel supply vacuum readings when the

engine is at full load and rated speed. **When the engine is accelerated to full throttle, full engine load is momentarily attained when the engine reaches rated speed.** Fuel pressure and vacuum gauge readings increase with engine speed until rated speed is reached. At this point the gauge hand hesitates and falls off due to governor action at speeds above rated speed. It is necessary to read the maximum swing of the pressure gauge hand quickly. The snap reading technique is not as accurate as measurements obtained with a dynamometer.

Snap reading gives an indication of fuel manifold pressure and fuel supply vacuum. **For a more dependable reading, use the average of five snap readings.**

3. Install a vacuum gauge (Cummins Tool ST-434) in the fuel supply line (Fig. 2). Check the suction restriction of the fuel supply line. If the vacuum reading exceeds 8 inches of mercury, determine the cause and correct.
4. Connect a manifold pressure gauge (Cummins Tool ST-435) at the manifold pressure gauge connection. Check the fuel manifold pressure at rated speed and full load. If the manifold pressure is not within specifications, correct as necessary.
5. Adjust valve and injector lash to specifications.
6. Check high-idle or maximum governed speed.

REAR THROTTLE SCREW ADJUSTMENT

1. Connect a manifold pressure gauge (Cummins ST-435) at the manifold pressure gauge connection (Fig. 2). Check the fuel manifold pressure at rated speed and full load.
2. Turn the rear throttle screw out until the highest fuel manifold pressure reading is obtained.
3. Turn the rear throttle screw in to reduce the fuel manifold pressure 5 psi.

Do not increase the rear throttle adjustment more than 5 psi or the engine speed at which peak torque occurs will change. Throttle restriction over 5 psi allows unauthorized adjustment to raise fuel manifold pressure, thereby overfueling the engine.

FORWARD THROTTLE SCREW OR THROTTLE LEAKAGE ADJUSTMENT

1. With the engine operating at idle speed, turn in the forward throttle screw until the engine gains speed. Back the screw out two full turns.

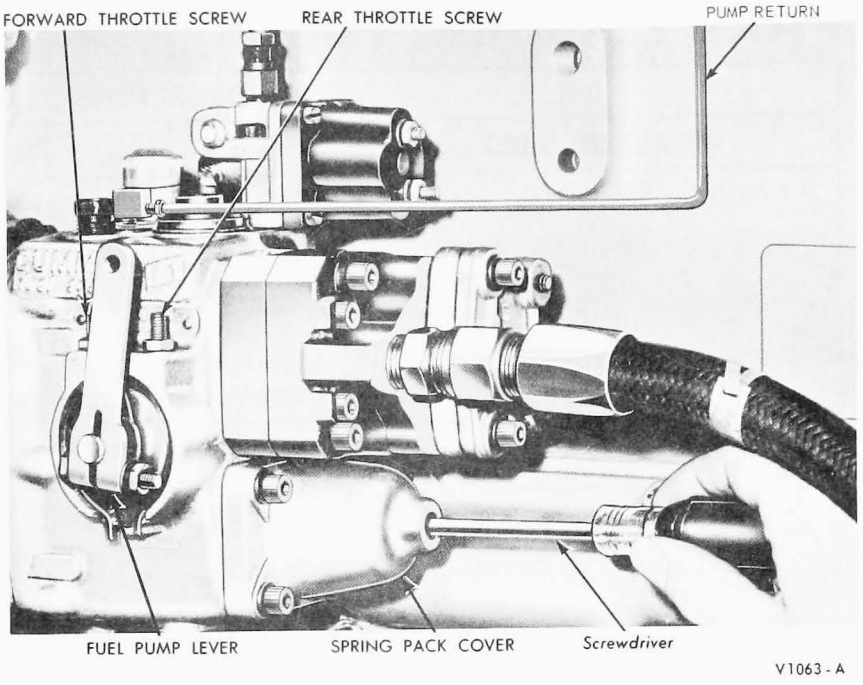

FIG. 1 Fuel Pump Adjustments

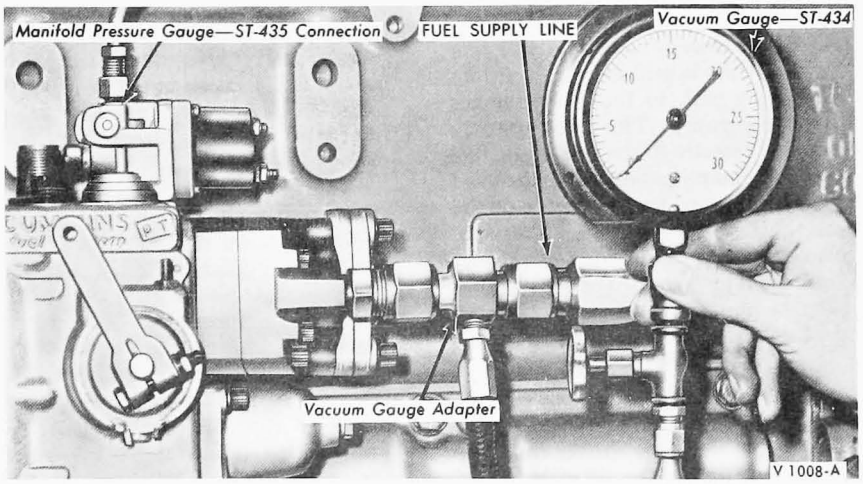

FIG. 2 Fuel Pump Gauge Connections

2. Stop the engine and remove the spring pack cover plug and adjust the idle governor screw (Fig. 1) to idle the engine at specified rpm (see specifications).
3. Operate the engine until it is purged of the air let in during Step 2.
4. Check the idle speed.
5. Check the deceleration; if it is too slow, the throttle leakage is excessive. If the engine falters or dies when idle speed is reached, the throttle leakage is too low. Adjust the screw to obtain permissible deceleration time.
6. Any change in the desired idle speed is made with the governor idle screw. Follow the sequence under Idle Speed Adjustments.

IDLE SPEED ADJUSTMENTS

1. With the engine stopped remove the pipe plug from the spring pack cover.
2. The idle adjustment screw is held in position with a spring clip. Turn the screw in to increase, or out to decrease the speed (Fig. 1).
3. Replace the pipe plug. With the engine running, air which collected in the spring pack housing will cause a rough idle temporarily. This will stabilize when the housing fills with fuel.

REMOVAL AND INSTALLATION

LIFT PUMP

CUMMINS DIESEL

Removal

1. Disconnect the accelerator return spring. Disconnect the hand throttle control, tachometer cable and accelerator rod at the fuel pump. Disconnect the lead to the fuel shut-off valve.
2. Disconnect the primer fuel pump line and fuel supply line at the fuel pump (Fig. 3). Remove the fuel outlet line from the shut-off valve and fuel manifold. Disconnect the fuel bleed line.
3. Remove the fuel pump mounting bolts. Remove the fuel pump, gasket and pump drive rubber buffer.

Installation

1. Clean the gasket surfaces of the fuel pump and air compressor.
2. Install the pump drive rubber buffer. Position a new fuel pump gasket on the air compressor and install the fuel pump. Torque the mounting bolts to specifications.
3. Connect the primer fuel pump line and fuel supply line to the fuel pump (Fig. 3). Connect the fuel outlet line to the fuel manifold and fuel shut-off valve. Connect the fuel bleed line.
4. Connect the accelerator rod, hand throttle control and tachometer cable to the fuel pump. Connect the fuel shut-off valve lead. Connect the accelerator return spring.
5. Check the accelerator linkage and adjust if necessary.
6. Start the engine and check for leaks.

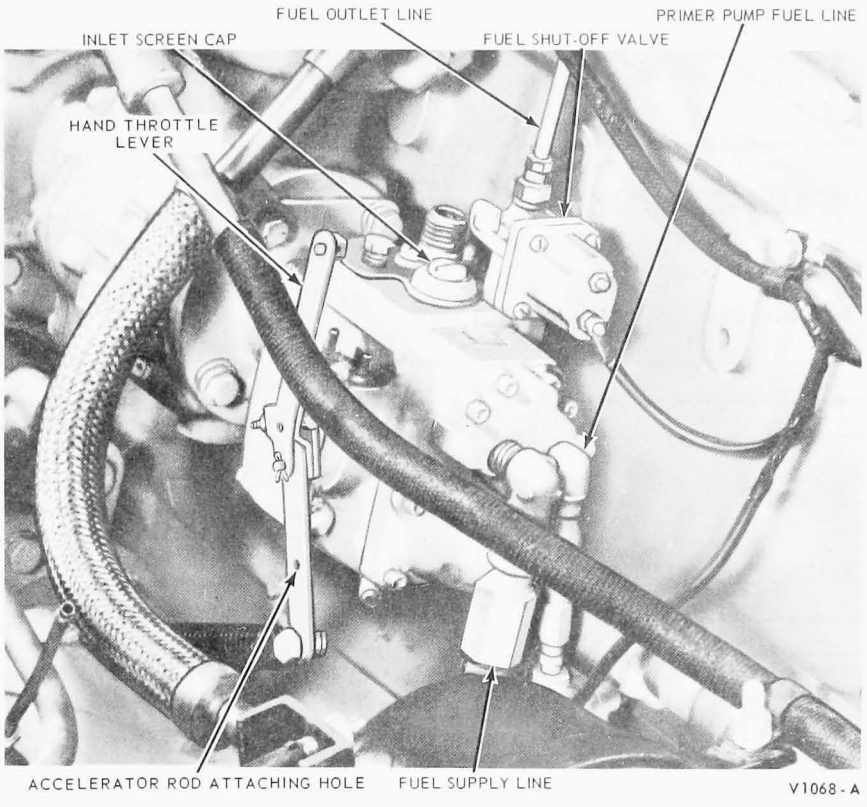

FIG. 3 Typical Lift Pump Installation

DETROIT DIESEL

Removal

1. Disconnect the fuel inlet and outlet lines at the fuel pump.
2. Disconnect the drain tube, if used.
3. Remove the three pump attaching bolt and seal assemblies, using wrench J-4242, and withdraw the pump from the blower end plate cover.
4. Check the drive coupling fork and, if broken or worn, replace it with a new coupling.

Installation

1. Affix a new gasket to the pump body mounting flange and locate the pump drive coupling fork over the squared end of the drive shaft, with the prongs of the fork directed away from the pump.
2. Place the fuel pump against the blower cover with the prongs of the drive coupling fork in registration with the slots in the drive disc on the blower rotor shaft.
3. Secure the pump to the blower cover with three bolt and seal washer assemblies.
4. Connect the inlet and outlet fuel tubes to the fuel pump.

FORD V-8 DIESEL

Removal

1. Disconnect the inlet and the outlet fuel lines from the pump (Fig. 4).
2. Remove the two attaching bolts, then lift the pump from the engine.

Installation

1. Clean the pump mounting surface on the engine and the pump.
2. Position the pump and new gasket so that the arm is contacting and properly centered on the fuel injection pump camshaft lobe. Install and tighten the attaching bolts to specifications.
3. Connect the fuel inlet and outlet lines to the lift pump (Fig. 4).

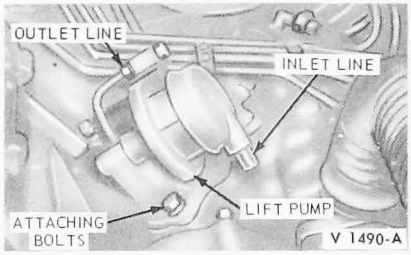

FIG. 4 Lift Pump Installed

LIFT PUMP SCREEN

Cummins Diesel

Removal

1. Remove the retainer cap from the

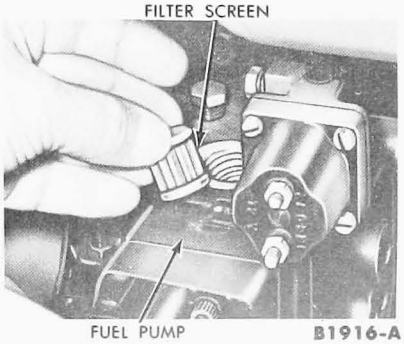

FIG. 5 Removing or Installing Lift Pump Filter Screen

fuel pump. Remove the spring and lift out the filter screen assembly (Fig. 5).

2. Remove the top screen retainer from the filter screen assembly. Wash the screen and magnet in cleaning solvent and dry with compressed air. Install the top screen retainer.

Installation

1. Install the filter screen, **with the hole down,** in the fuel pump.
2. Install the spring and retainer cap. Torque the retainer cap to specifications.

DESCRIPTION

A dry type air cleaner is standard equipment on all Ford trucks equipped with Diesel engines. Air is filtered through a pleated, chemically-treated paper element to remove contaminants before entering the engine induction system.

Air cleaners on W, WT, L, LN, LT and LNT Series trucks are equipped with centrifuge fins on the filter element. Air passing through the fins is sent into a circular motion which causes heavy particles of dust and dirt to be thrown out of the air stream. The dirt is collected in the dust port and expelled through a dump valve.

Most air cleaners are equipped with an air restriction gauge which indicates red when the air cleaner needs servicing.

Air cleaner installations are shown in Figs. 1 through 7.

REMOVAL AND INSTALLATION

FILTER ELEMENT

Removal

1. Remove the dust cup or cover.
2. Remove the filter element from the air cleaner body.

Installation

Before installing a new or cleaned element in the air cleaner, check the following items:

1. Gasket surfaces should be clean and undamaged.
2. Outlet tube should be clean and undamaged.
3. All rags and tools must be removed from the air cleaner body.
4. Element should be dry and free of holes, ruptures, damaged gaskets or dents in end covers and liners.
5. Element retaining nut or bolt should have the gasket washer attached and it should be in good condition.

After the air cleaner, element, dust cup and other parts are found to be in good condition, reassemble the parts as follows:

1. Install the element and tighten the wing nut or bolt securely. Hand tightening is sufficient. Make sure the rubber face of the washer seals against the element.
2. Install the dust cup or cover. Make sure gasket (if supplied) is in place. Replace a worn or damaged gasket.
3. Tighten dust cup clamp or cover securely.

Be sure a seal is made between the dust cup and the air cleaner body. A leak would reduce element life.

CLEANING AND INSPECTION

AIR INLET RESTRICTION CHECK

The best method for determining dry-type air cleaner maintenance periods is through air restriction checks.

At Air Cleaner

A mechanical restriction indicator is installed on the air cleaner to indicate excessive air restriction. The gauge shows completely red in the indicator window when restriction reaches 25 inches of water (Fig. 8).

FIG. 8 Air Cleaner Restriction Indicator

If the restriction indicator indicates red:

Clean or replace dry-type cleaner element.

Replace damaged air piping, rain shield or housing.

Remove excessive bends or other source of restriction in air piping.

Reset the restriction indicator after servicing the air cleaner.

At Engine

1. On naturally aspirated engines, attach vacuum gauge or water manometer in the middle of the intake manifold or on the air intake piping. When located in the air intake piping, the adaptor must be perpendicular to the air flow and not more than six inches from the air intake manifold connection.
2. On turbocharged or supercharged engines, attach the checking fixture on pipe diameter upstream from the supercharger or turbocharger in a straight section of tubing.
3. Idle the engine until normal operating temperature is reached.
4. Operate engine at rated speed full-load and take reading from vacuum gauge or manometer. Air restriction must not exceed 25 inches of water or 1.8 inches of mercury.
5. If air restriction exceeds 25 inches of water or 1.8 inches of mercury:

Clean or replace dry-type cleaner element.

Replace damaged air piping, rain shield or housing.

Remove excessive bends or other source of restriction in air piping.

FILTER ELEMENT

Washing in water or blowing with compressed air are two accepted methods for cleaning elements of the **Cyclopac** air cleaners. If elements regularly contain substantial amounts of soot or oil fumes, washing in water works better than compressed air. If the contaminant on the element is dust, either method works well. Elements that are cleaned with compressed air can be put back into service immediately. Washed elements must be dried before they can be used.

Some elements are partially covered by a plastic sleeve with fins. The covered portion can be cleaned with water or air without removing the sleeve. Use a stiff fiber (not wire) brush to remove oil and grease deposits from the sleeve and fins. **Do not remove plastic sleeve and fins from the element.**

CLEANING WITH COMPRESSED AIR

1. Direct a jet of clean, dry air from the inside of the filter element, perpendicular to the pleats. **Pressure at air nozzle must not exceed 100 psi.**
2. Move the air jet up and down along the pleats, slowly rotating the element, until no more dust is being removed. **Be certain that the element is not ruptured by the nozzle or the air jet.**

CLEANING WITH WATER

The elements can be cleaned by washing with water and a good non-sudsing detergent. Direct a jet of clean, dry air from the inside of the filter element. When the loose dust and soot have been removed, the element is ready to be washed.

1. Dissolve the detergent in a small amount of cool water.
2. Add warm (approximately 100 degrees F) water to get the proper proportions of detergent and water (about one cup of detergent to five gallons of water).
3. Soak the element in the solution for at least 15 minutes.
4. Agitate the element for about 2 minutes to loosen the dirt.

Never use gasoline or solvent to clean elements.

5. Rinse the element with clean water until the water coming through the element is clean. Water pressure from a hose or tap should not be over 40 psi. Air-dry the element thoroughly before using.

Mechanized drying methods can be used. However, heated air (maximum temperature 180 degrees F) must have some circulation. **Do not use light bulbs for drying elements.**

6. After cleaning the filter element with air or water, inspect the element for damage. Look for dust on the clean air side, the slightest rupture or damaged gaskets. A good method to detect ruptures in the element is to place a light inside the element and look toward the light from the outside. A hole in the element, even a very small one, will pass dust to the engine and cause wear.

DUST CUP

1. Stop the engine.
2. Remove the dust cup, then remove the baffle from the cup and empty the dust.
3. Replace the baffle in the cup, making sure that the baffle is properly seated. Check the dust cup sealing edge for damage. Check the dust cup gasket (if so equipped).
4. Replace the dust cup and make sure it is properly positioned on the air cleaner body. On horizontally mounted models, the proper cup position is indicated by the arrows located on the bottom of the cup. Also, the slot in the dust cup baffle must be at the top.

EVACUATOR VALVE

Evacuator valve lips must be kept free from debris. Mud and chaff can lodge in the lips and hold them open during operation. Check the lips periodically and keep them clean. The valve lips should be open only when the engine is at low idle or stopped. The lips must point down to function.

On W-and WT-Series trucks a protection hose is provided for the evacuator valve. The protection hose is to be installed toward the rear of the vehicle.

AIR CLEANER BODY

Before re-installing the filter element, remove any foreign material (leaves, lint, or other matter) that may have collected inside the air cleaner body. Inspect the inside of the body for dents or other damage that would interfere with air flow or with the fins on the element or inside the body. Repair body dents, being careful not to damage sealing surfaces. Wipe out the inside of the body with a clean rag to remove any dirt.

When the air cleaner is mounted on the engine, use compressed air to clean the air cleaner body only with the element in place.

PART 25-50 Fuel Tanks and Lines

Refer to Part 24-50 for service of the fuel tanks and lines.

DESCRIPTION

FUEL FILTERS

FORD V-8 DIESEL FUEL FILTER

A two-stage fuel filter is provided on the pressure side of the lift pump. Since the filter is located on the pressure side of the pump, the possibility of air induction into the system is eliminated. The fuel filter element is the spin-on type.

CUMMINS DIESEL FUEL FILTER

A cannister-type fuel filter is provided on the left rear side of the engine (Fig. 1). The filter is located between the fuel tank and suction side of the pump.

DETROIT DIESEL FUEL FILTER

A fuel strainer and a fuel filter is provided in the Detroit Diesel Engine fuel system (Fig. 2). The fuelstrainer is located between the fuel tank and the suction side of the lift pump.

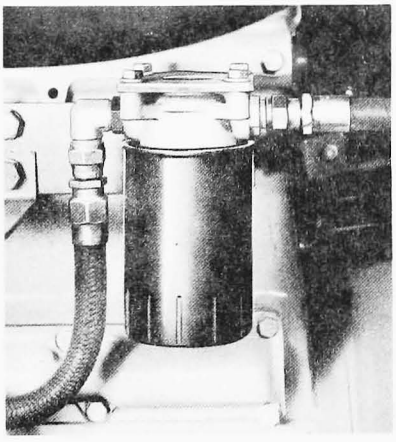

FIG. 1 Typical Engine Mounted Fuel Filters

The fuel filter is located between the fuel lift pump and the fuel inlet manifold.

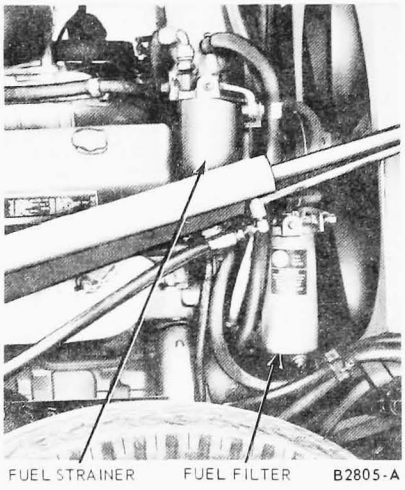

FIG. 2 Detroit Diesel Fuel Filter

REMOVAL AND INSTALLATION

FORD V-8 AND CUMMINS DIESEL FUEL FILTER

Removal

1. Turn the fuel filter element counterclockwise until it is free of the base.
2. Discard the filter element.

Installation

1. Clean the seal surface on the filter base thoroughly.
2. Wipe up any fuel that was spilled when removing the old filter.
3. Coat the seal of the new filter with oil.
4. Thread the filter onto the base until the seal contacts the base, then tighten it one additional 1/2 turn.

DETROIT DIESEL FUEL STRAINER OR FUEL FILTER

This procedure applies to either the fuel strainer or the fuel filter.

Removal

1. Place a container under the strainer or filter and open the draincock. Loosen the cover nut or bolt just enough to allow the fuel oil to drain out freely; then, close the draincock.
2. While supporting the shell, unscrew the cover nut or bolt and remove the shell and element. Also remove and discard the cover nut retaining ring, if used.
3. Remove and discard the filter element and shell gasket. Wash the shell thoroughly with clean fuel oil and dry it with compressed air.

Installation

1. Place a new element over the shell stud and push it down against the element seat. Close the draincock; then fill the shell about two-thirds full with clean fuel oil.
2. Place a new shell gasket in the recess of the shell, also place a new gasket on the cover nut or bolt.
3. Place the shell and element into position under the cover. Then, start the cover nut or bolt on or into the shell stud.
4. With the shell and the gasket properly positioned, tighten the cover nut just enough to prevent fuel leakage.
5. Remove the pipe plug at the top of the filter or strainer and complete filling of the shell with fuel.

   Fuel System Primer J5966 may be used to prime the entire fuel system.
6. Run the engine and check the fuel system for leaks.

SPECIFICATIONS

FUEL FILTER ELEMENT

Spin-on Type	Tighten until seal contacts base, then tighten one additional half turn.
Cannister Type	Tighten cover bolt just enough to prevent leakage at seal.

ADJUSTMENT

F-AND B-6000-7000 SERIES TRUCKS WITH FORD V-8 DIESEL ENGINES

Refer to Figs. 1 and 2.

1. Depress the accelerator pedal to the stop bolt on the floor.
2. Adjust the accelerator rod until the throttle lever is at the wide open (high idle) position.
3. Shorten the rod an additional two turns.

C-6000-8000 SERIES TRUCKS WITH FORD V-8 DIESEL ENGINES

Refer to Fig. 3.

1. Release the cab locks. Tilt the cab forward and lock into the forward position.
2. Loosen the hand throttle control cable clevis at the bellcrank.
3. Place a spacer 0.200 inch thick between the pedal and the pedal stop. Depress the pedal against the spacer.
4. Adjust the rod assembly at the throttle lever until the lever is in the wide open (high idle) position.
5. With the hand throttle control handle and the throttle lever in the idle (low idle) position insert the hand throttle control cable into the clevis. Tighten the clevis clamp screw.
6. Operate the hand throttle control

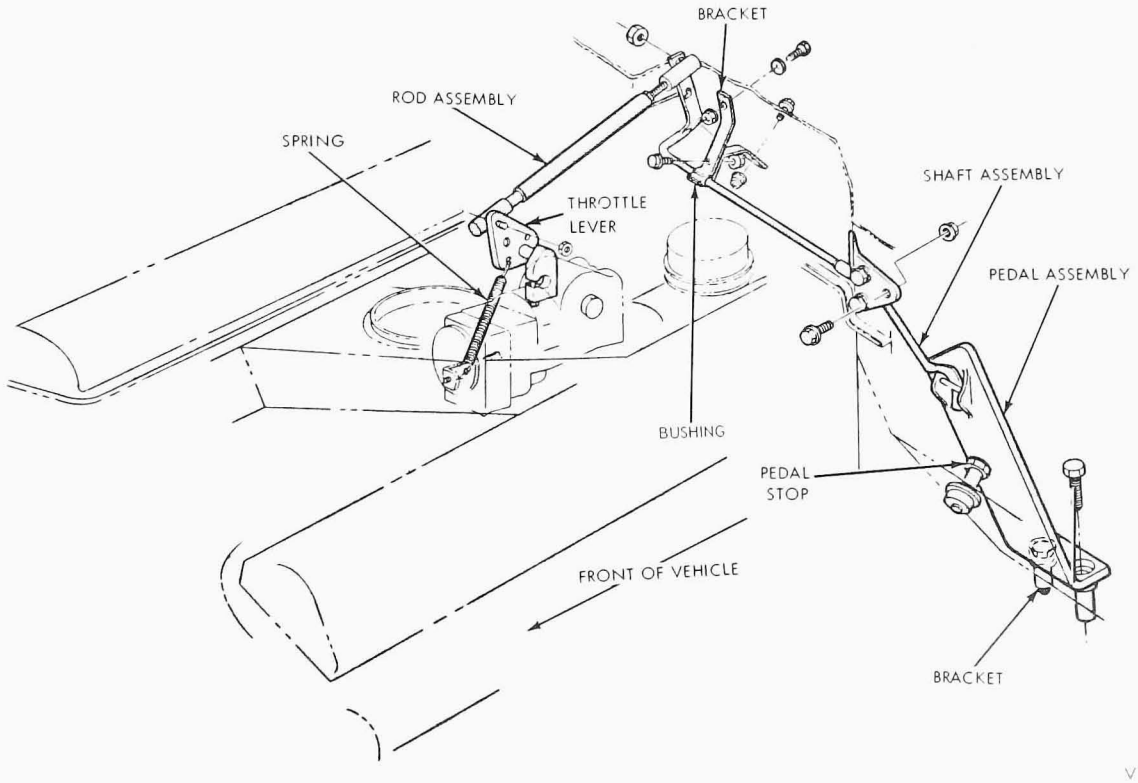

FIG. 1 Throttle Linkage—F-6000-7000 Series with Ford V-8 Diesel Engines

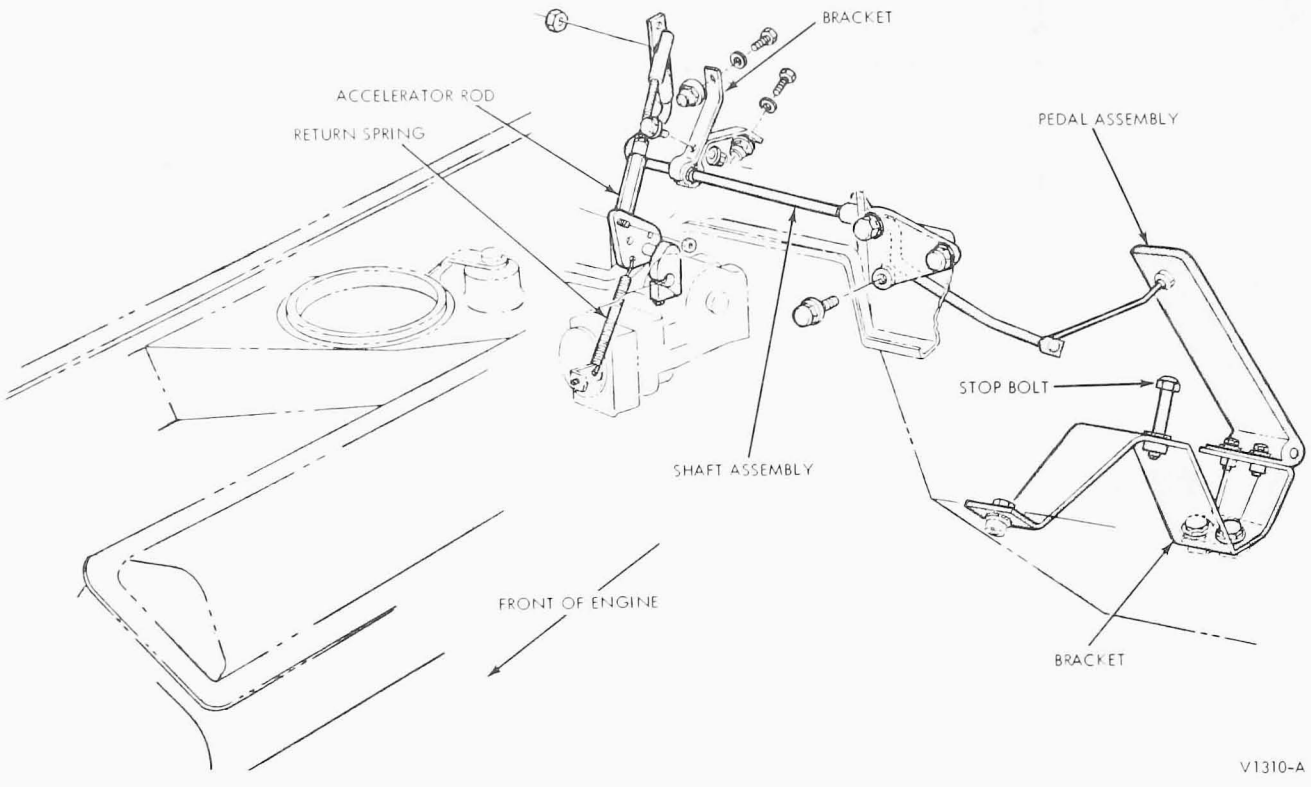

FIG. 2 Throttle Linkage—B-6000-7000 Series with Ford V-8 Diesel Engine

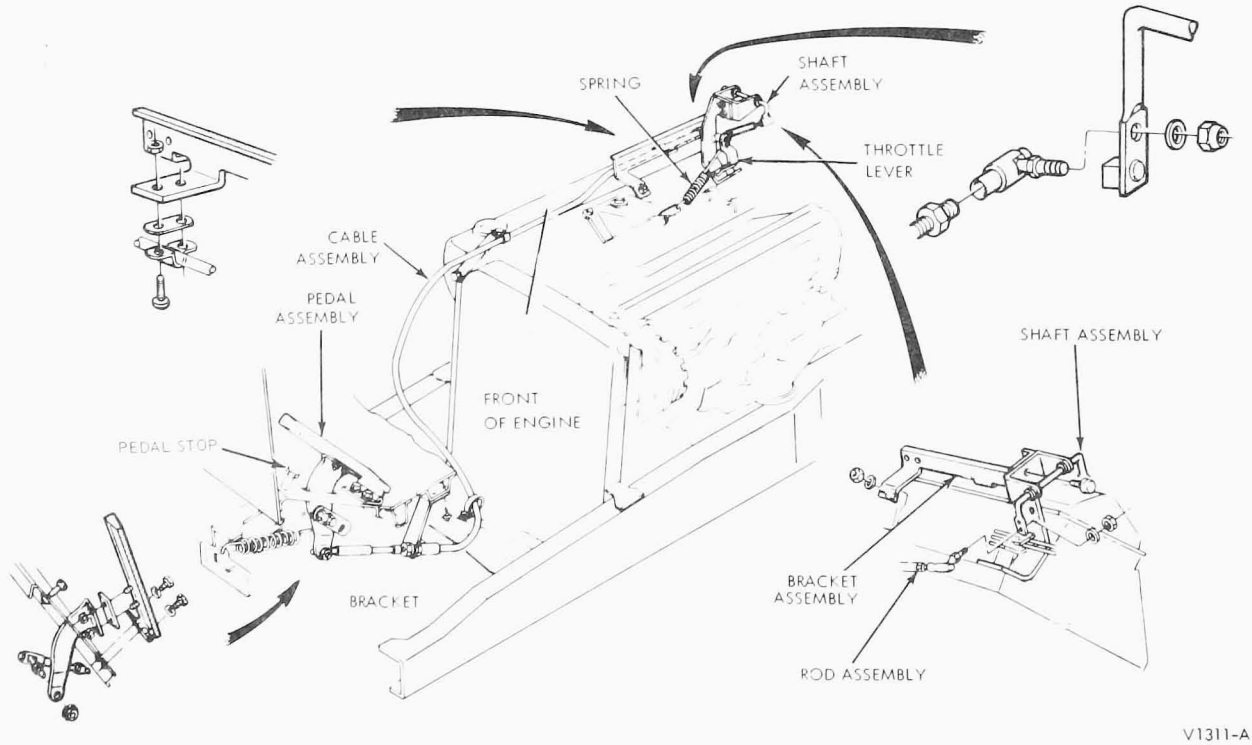

FIG. 3 Throttle Linkage—C-6000-8000 Series with Ford V-8 Diesel Engine

handle to ensure full travel from idle (low idle) to wide open (high idle) positions.
7. Lower the cab and lock into position.

L-LN-LT-AND LNT-6000-8000 SERIES TRUCK WITH FORD V-8 DIESEL ENGINES

Refer to Fig. 4.
1. Loosen the hand throttle control cable retaining clamp at the bracket and the clevis at the throttle lever.
2. With the pedal held against the stop adjust the accelerator rod until the throttle lever is in the wide open (high idle) position. Shorten the rod an additional two turns.
3. Push the hand throttle control handle into the idle position. With the throttle lever in the idle (low idle) position, insert the end of the hand throttle control cable into the clevis and tighten the clamp screw. Tighten the cable retaining clamp on the bracket.
4. Operate the hand throttle control knob to insure full travel from idle (low idle) to wide open (high idle)position.

L-LN-LT-AND LNT-9000 SERIES TRUCKS WITH CUMMINS NH ENGINES

Refer to Fig. 5.
1. Loosen the hand throttle control cable retaining clamp at the bracket.
2. With the pedal held against the stop, adjust the accelerator rod length until the fuel pump throttle lever is in the wide open position. Shorten the accelerator rod an additional two turns.
3. Push the hand throttle control cable handle to the idle position. Position the fuel pump throttle lever in the idle position and tighten the hand throttle control cable retaining clamp at the bracket.
4. Pull the hand throttle control cable to the wide open position and check to make sure the fuel pump throttle lever is in the wide open position.

W-AND WT-9000 SERIES TRUCKS WITH CUMMINS ENGINES

Refer to Fig. 6.
1. Release the cab locks and tilt the cab forward.
2. Disconnect the accelerator spring and the accelerator rod assembly at the injector fuel pump lever, located on the engine.
3. Set the injector fuel pump lever to the idle position.
4. Position the accelerator shaft assembly so that the left-hand lever is horizontal and attach the accelerator rod assembly. Attach the return spring.
5. Loosen the hand throttle control cable retaining clip and clamps. With the fuel pump lever in the idle position, slide the hand throttle control cable through the lever assembly and the disc-type clamp. Tighten the clamp.
6. Pull the handle on the throttle control cable outward to the wide-open position. Tighten the clamp on the hand throttle control bracket and the cable clip. This will secure the cable assembly in relation to the injector fuel pump wide-open throttle position.
7. With the cab in the retracted and locked position, depress the accelerator pedal fully and adjust the accelerator pedal to slip shaft

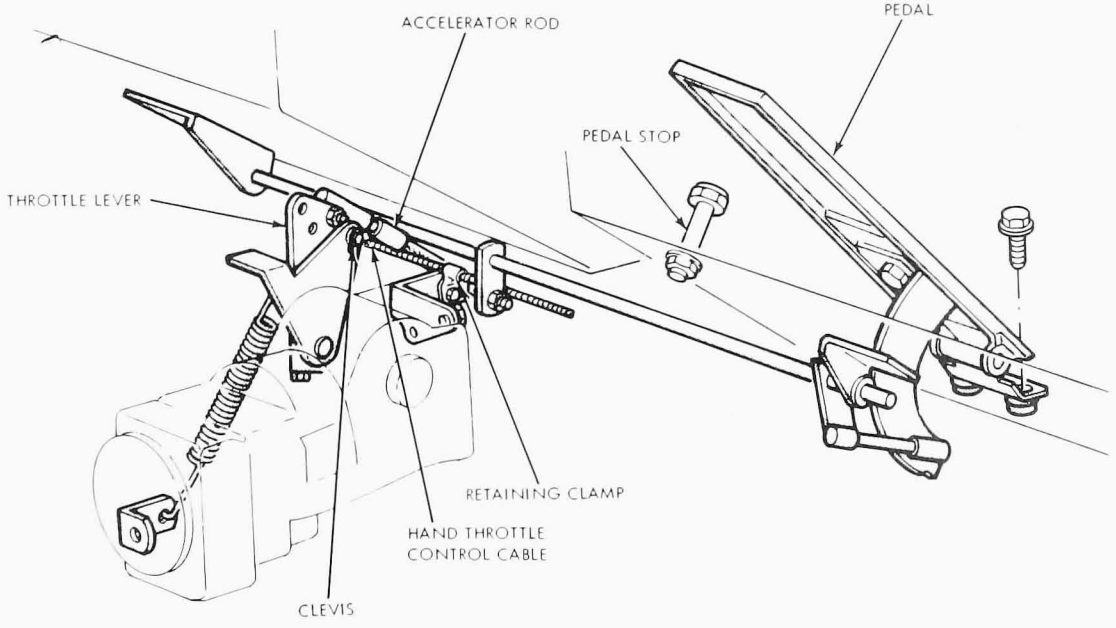

FIG. 4 Throttle Linkage—L-LN-LT-LNT 6000-8000 Series with Ford V-8 Diesel Engine

rod until the accelerator pedal just touches the stop bolt.

L-LN-LT-AND LNT-9000 SERIES TRUCKS WITH DETROIT DIESEL 6-71 ENGINES

Refer to Fig. 7.

1. Loosen the hand throttle control cable clevis at the throttle lever and the retaining clamp at the bracket.
2. With the throttle lever in the idle (low idle) position adjust the short accelerator rod so that the long bellcrank lever is in the position shown in Fig. 7.
3. Loosen the clamp screw on the short bellcrank lever and position it as shown in Fig. 7.
4. With the accelerator pedal held against the stop, adjust the long accelerator rod until the throttle lever is in the wide open (high idle) position. Shorten the rod an additional two turns.
5. Push the hand throttle control handle to the idle position.
6. With the throttle lever at the idle (low idle) position, insert the end of the hand throttle control cable into the clevis and tighten the clamp screw.
7. Tighten the hand throttle control cable retaining clamp at the bracket.
8. Operate the hand throttle control handle to ensure full travel from idle (low idle) to wide open (high idle) positions.
9. Loosen the fuel shut off control cable at the clevis and retaining clamp. Push the control handle to the ON position.
10. Position the fuel shut off lever in the ON position and insert the end of the control cable into the clevis. Tighten the clevis clamp screw and the cable retaining clamp at the bracket.
11. Operate the fuel shut off handle to insure full travel from ON to OFF positions.

W-AND WT-9000 SERIES TRUCKS WITH DETROIT DIESEL 6-71 ENGINES

Refer to Fig. 8.

1. Loosen the hand throttle control cable at the clevis and retainer clamp.
2. With the throttle lever at the idle (low idle) position adjust ROD A until LEVERS B and C are as shown in VIEW W.
3. Position BELLCRANK G as shown in VIEW X and adjust RODS D and F to acquire a good working angle with the levers on BELLCRANK E.
4. Slide the hand throttle control cable through the retaining bracket and into the throttle lever. Tighten the cable retaining screw in the throttle lever.
5. Pull the throttle control handle to the full open position and tighten the bracket.
6. Push the fuel shut off control handle to the ON position. With the fuel shut off lever in the ON position insert the control cable into the clevis and tighten the clamp screw. Tighten the cable retaining clamp at the bracket. Operate the fuel shut off control handle to ensure full travel from the ON to OFF positions.
7. With the cab in the retracted and locked position depress the

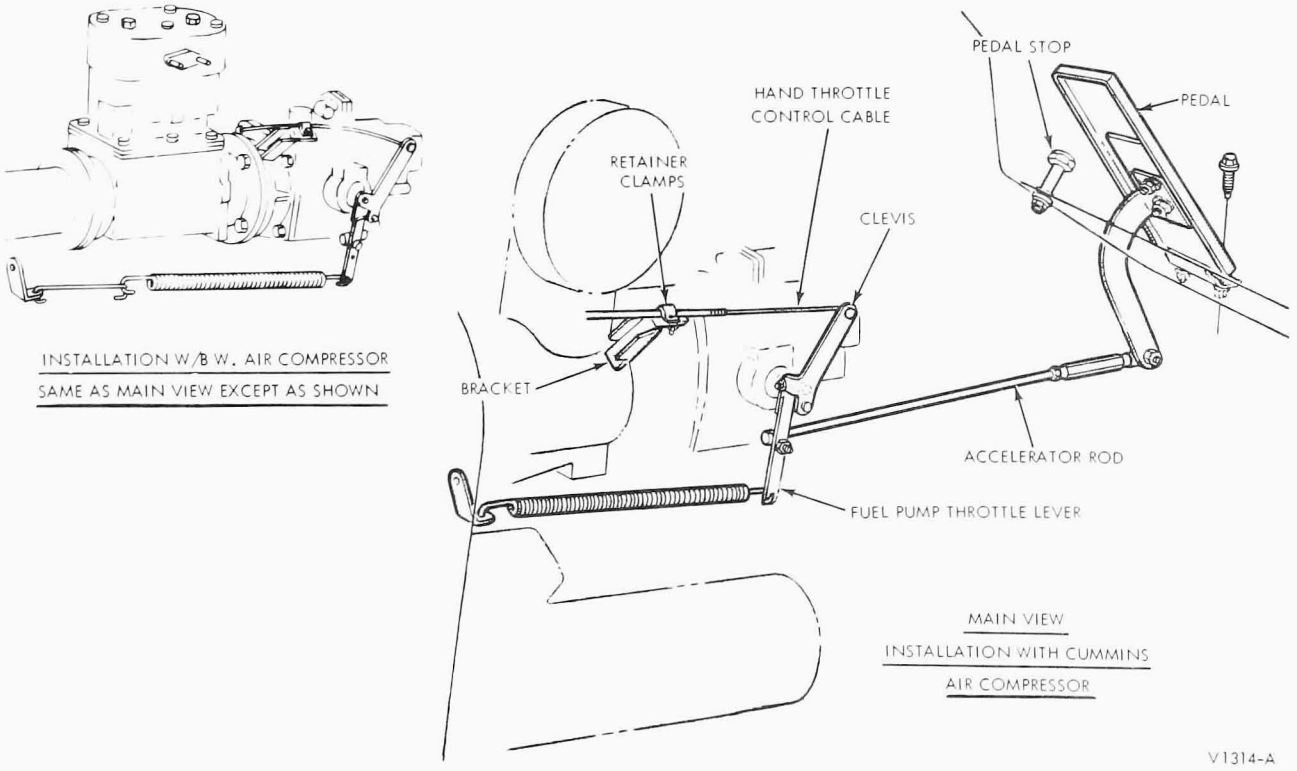

FIG. 5 Throttle Linkage—L-LN-LT-LNT Series with NH Series Diesel Engines

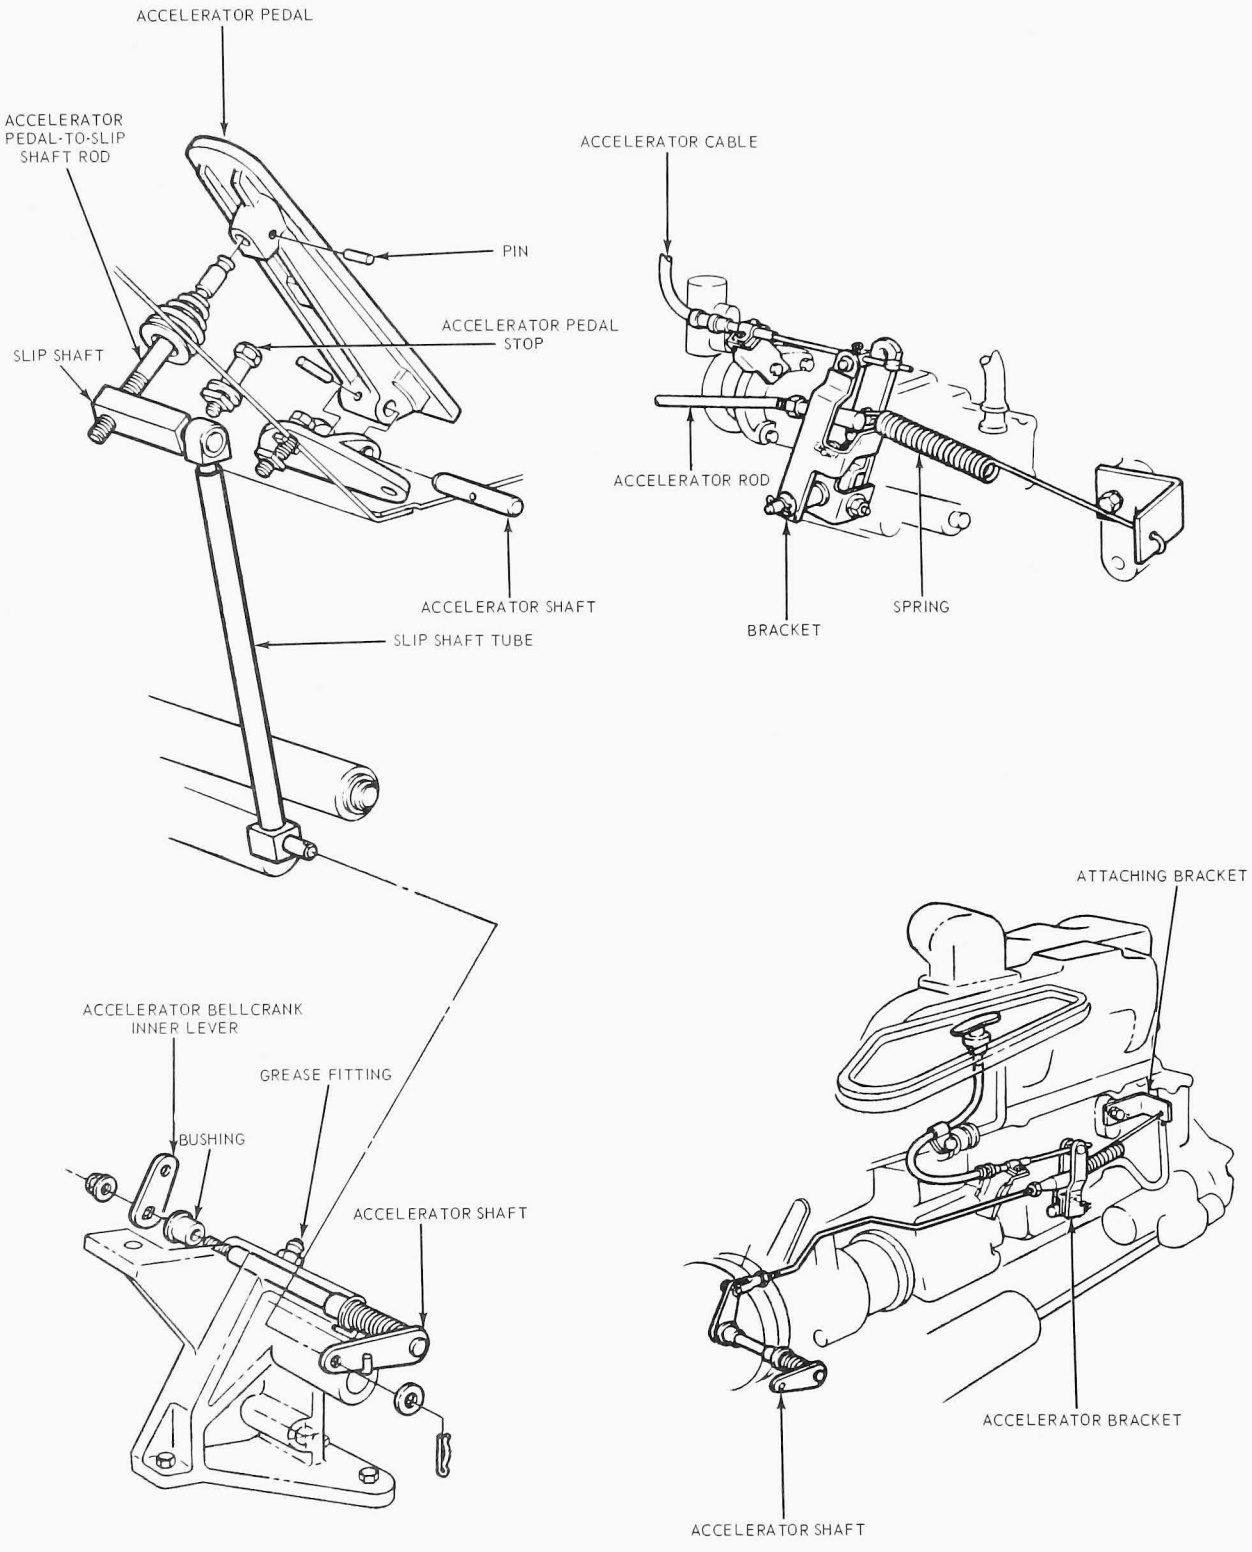

V 1014-B

FIG. 6 Throttle Linkage—W and WT Series with NH Series Diesel Engine

accelerator pedal fully and adjust ROD H until the pedal just touches the stop bolt.

L-LN-LT-AND LNT-8000 SERIES TRUCKS WITH DETROIT DIESEL 6V-53 ENGINES

Refer to Fig. 9.

1. Loosen he hand throttle and fuel shut off control cable retaining clamps at the bracket.
2. Loosen the throttle lever clamp bolt.
3. Insert a 0.090 diameter locating pin in the alignment holes of the bellcrank assembly.
4. Insert an Allen wrench in the top of the throttle shaft and rotate the shaft to the wide open (high idle) position. Tighten the throttle lever clamp bolt.
5. Remove the locating pin from the bellcrank assembly.
6. Depress the accelerator pedal against the stop and adjust the accelerator rod until the throttle lever is in the wide open (high idle) position. Shorten the rod an additional two turns.
7. Place the hand throttle control cable in the idle (low idle) position. With the throttle lever in the idle position tighten the hand throttle control cable retaining clamp at the bracket.
8. Operate the hand throttle control handle to ensure full travel from the idle (low idle) to wide open (high idle) positions.
9. Place the fuel shut off control in the ON position. With the fuel shut off lever in the ON position, tighten the control cable retaining clamp at the bracket. Operate the fuel shut off control to ensure full travel from the ON to OFF positions.

L-AND LT-9000 SERIES TRUCKS WITH DETROIT DIESEL 8V-71 ENGINES

Refer to Fig. 10.

1. Loosen the hand throttle control cable at the clevis and retaining clamp.
2. Loosen the clamp screw on the throttle lever. Install a 1/8 inch drill bit through the alignment holes on the bellcrank assembly.
3. Turn the throttle (governor) shaft to the wide open (high idle) position and tighten the throttle lever clamp bolt.
4. Remove the 1/8 inch drill bit from the alignment holes.
5. With the pedal against the stop, adjust the accelerator rod until the throttle lever is at the wide open (high idle) position. Shorten the accelerator rod an additional two turns.
6. Push the hand throttle control handle to the idle (low idle) position. Position the throttle lever at the idle (low idle) position and insert the end of the hand throttle cable into the clevis. Tighten the clevis clamp and the cable retainer clamp.
7. Operate the hand throttle control and check for full travel from idle to wide open position.
8. Loosen the fuel shut off control cable at the clevis and clamp. Push the control handle to the ON position.
9. Position the fuel shut off lever in the ON position and insert the end of the control cable into the clevis. Tighten the clevis clamp screw and the cable retaining clamp at the bracket.
10. Operate the fuel shut off handle to

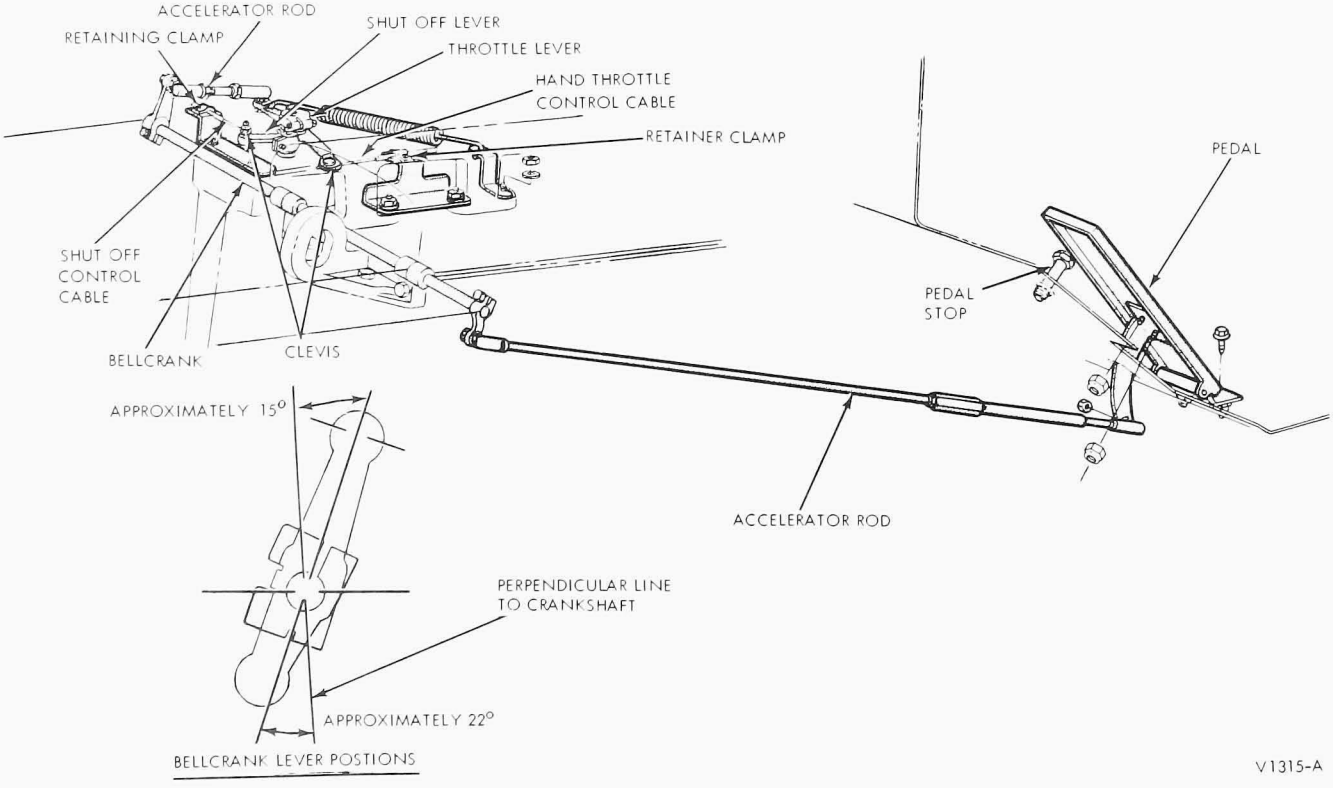

FIG. 7 Throttle Linkage—L-LN-LT-LNT-9000 Series with 6-71 Diesel Engine

insure full travel from the ON to OFF positions.

W-AND WT-9000 SERIES TRUCKS WITH DETROIT DIESEL 8V-71 ENGINES

Refer to Fig. 11.

1. Release the cab locks and tilt the cab forward.
2. Disconnect the throttle return spring. Disconnect the bellcrank to cross-over shaft rod at the accelerator bellcrank inner-lever. Disconnect the vertical accelerator rod assembly at the accelerator shaft and housing assembly. Disconnect the fuel pump rod at the vertical accelerator rod.
3. Rotate the vertical accelerator rod to the idle position and lock into place using a 1/8 inch drill rod through the alignment holes (Fig. 11). Install the fuel pump rod on the vertical accelerator rod.
4. Position the accelerator shaft assembly so that the left (outer) lever is horizontal. Install the cross-over rod to the inner lever of the accelerator shaft assembly. Connect the throttle return spring.
5. Slide the hand throttle cable through the hand throttle lever clevis (in idle position) and tighten the retaining screw in the hand throttle lever clevis.

Pull the handle on the throttle control cable outward to the wide-open position. Tighten the throttle cable to support bracket clamp and the throttle control cable slips. This will secure the cable assembly in relation to the injector fuel pump wide open throttle position.

6. Position the fuel shut-off control lever assembly on the engine to the ON position. Slide the fuel shut-off control cable through the lever and tighten the cable clamp.
7. Pull the handle on the fuel shut-off control cable outward to the shut-off position. Tighten the shut-off cable retaining clips and clamps. This will secure the cable assembly in relation to the fuel shut-off position.
8. With the cab in the retracted and locked position, depress the accelerator pedal fully and adjust the accelerator pedal to slip shaft rod until the accelerator pedal just touches the stop bolt.

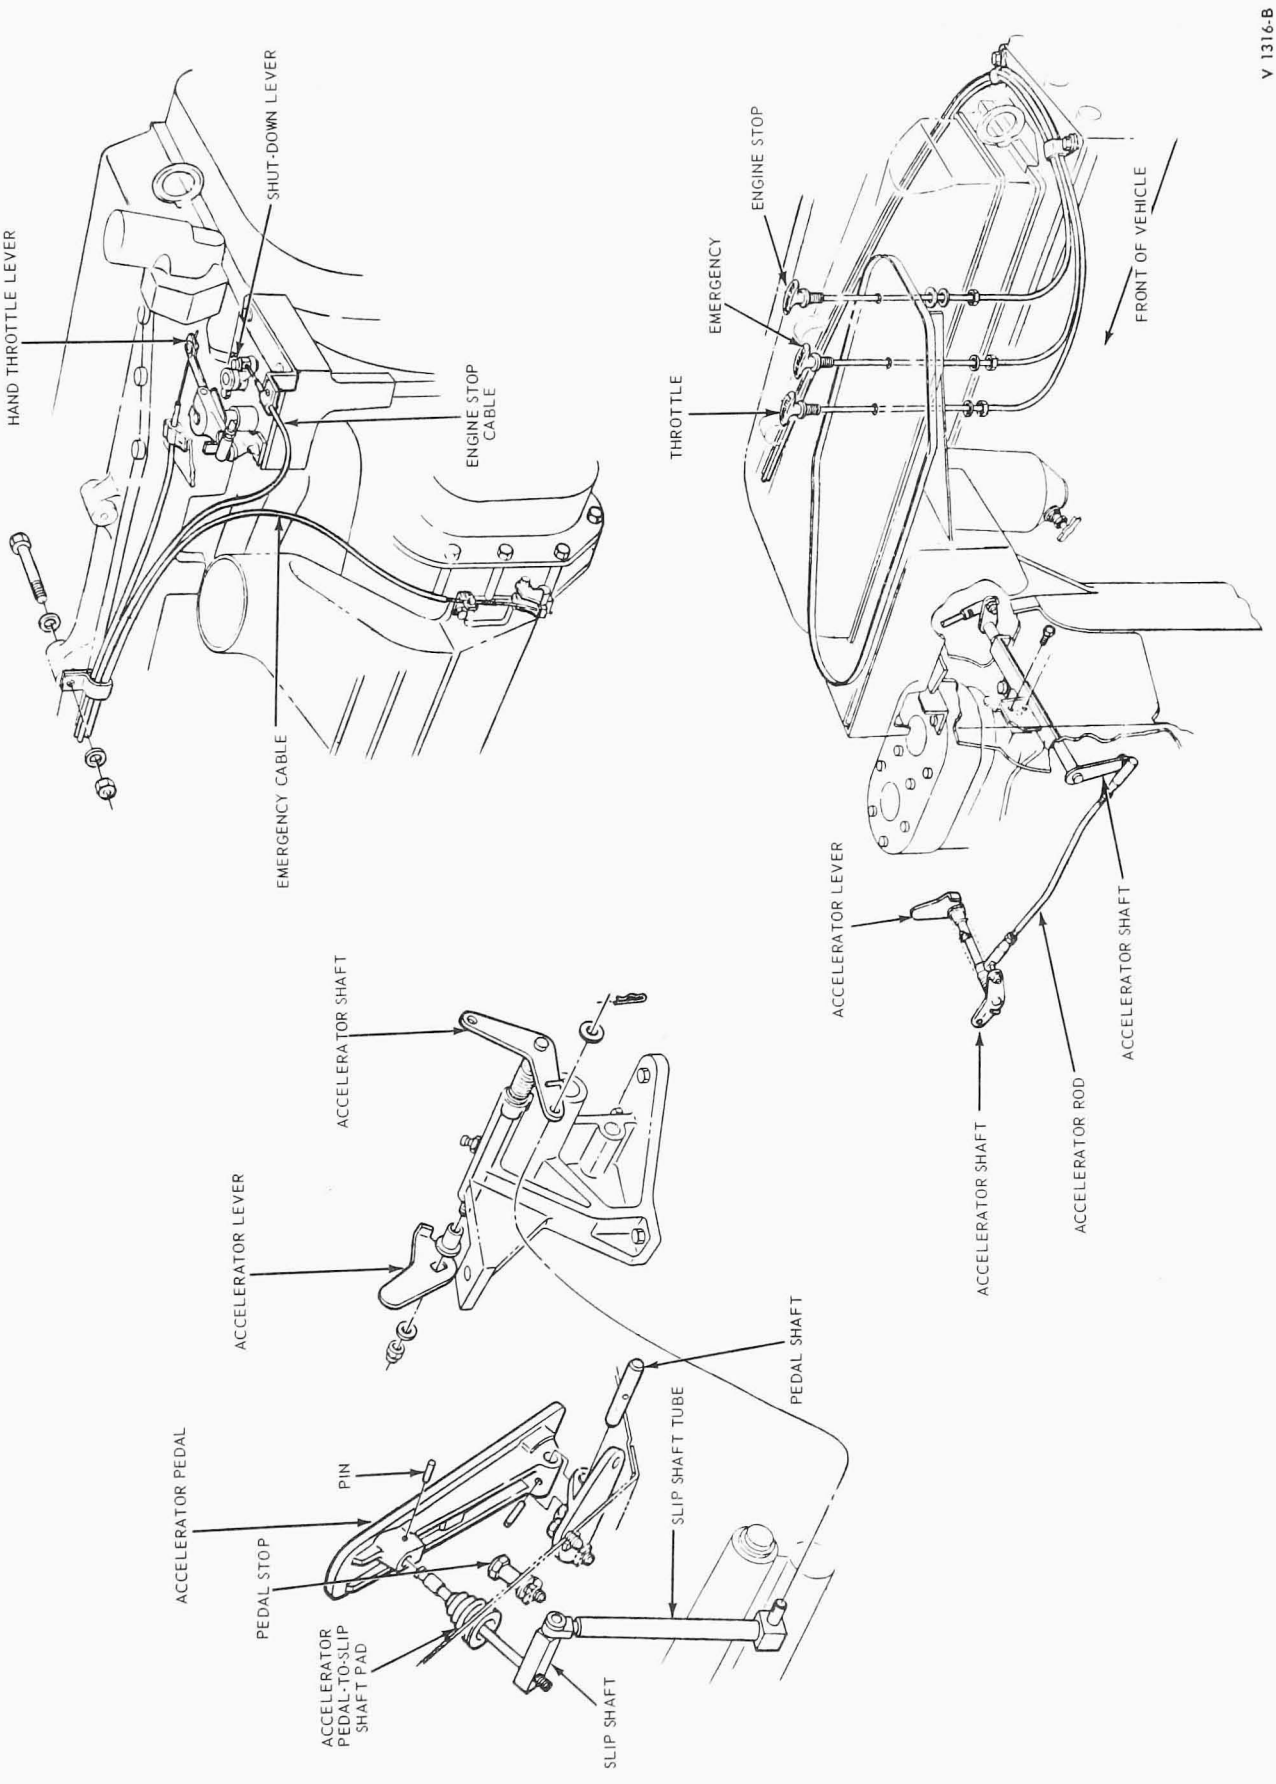

FIG. 8 Throttle Linkage—W and WT-9000 Series with 6-71 Diesel Engine

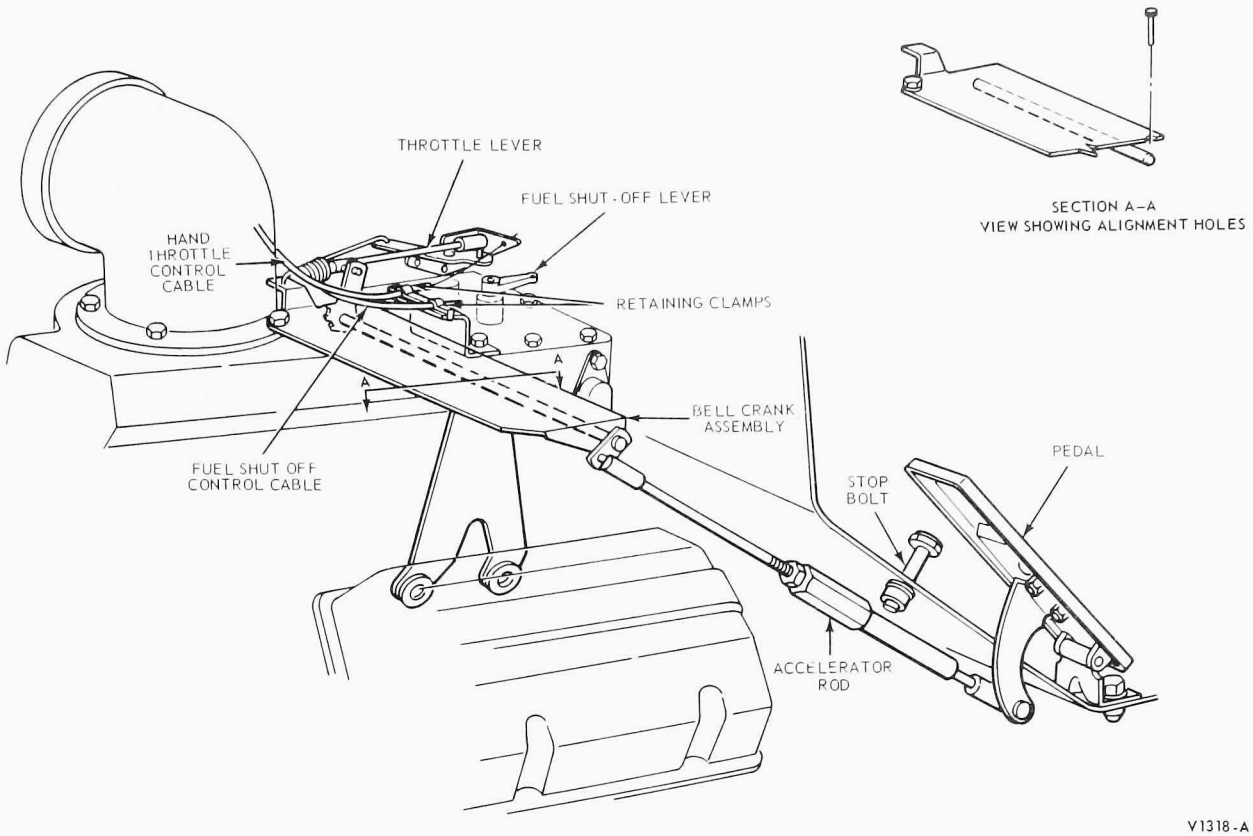

FIG. 9 Throttle Linkage—L-LN-LT-LNT 8000 Series with 6V-53 Diesel Engine

EXHAUST SYSTEM		EXHAUST SYSTEM - Continued	
Adjustment	01-01	Description	01-01
Alignment	01-02	SPECIFICATIONS	01-02

DESCRIPTION

With the exception of super duty gasoline engines, a single exhaust system is used on all trucks with gasoline engines. Trucks with a super duty engine use a dual exhaust system.

The Y-type inlet pipe on V-8 engines may be either a one piece unit or a two piece assembly utilizing a crossover pipe extending to the left exhaust manifold outlet.

The exhaust systems used on the diesel engines vary between engine and truck models.

Illustrations given in the following parts of this Group show the components used for different applications.

The dual exhaust system used on Super Duty Engines consists of an inlet pipe, a muffler and an outlet pipe for each bank of the engine.

The location and type of exhaust system gaskets, retaining clamps and support brackets are shown in the respective exhaust system illustrations.

This Part covers general exhaust system alignment procedures and specifications.

For exhaust system component removal, disassembly, assembly and installation, refer to the latter parts of this Group.

Always refer to the Master Parts Catalog for parts usage and interchangeability before replacing a component part of the exhaust system.

ADJUSTMENTS

Inspect inlet pipes, outlet pipes and mufflers for cracked joints, broken welds and corrosion damage that would result in a leaking exhaust system. Inspect the clamps, brackets and insulators for cracks and stripped or badly corroded bolt threads. When pipe clamp(s) are loosened and/or removed to replace a pipe or muffler, replace the clamp(s) if there is reasonable doubt that its service lift is limited.

The exhaust system must be free of leaks, binding, grounding and excessive vibrations.

These conditions are usually caused by loose, broken or misaligned clamps, brackets or pipes. If any of these conditions exist, check the exhaust system components and alignment. Align or replace as necessary.

EXHAUST SYSTEM ALIGNMENT

The locations of components are given in the illustrations in the following Parts. Perform the following procedure to align the complete exhaust system.

1. Loosen the pipe connection clamps and the pipe support bracket clamps. Loosen the inlet pipe to exhaust manifold attaching nuts.
2. Torque the exhaust manifold to inlet pipe attaching nuts evenly and alternately to specifications so that the pressure on the gasket and inlet pipe flanges will be uniform on both sides.
3. Work from the front and progressively align the exhaust system components and clamps at the various pipe connections to relieve binds and displaced pipe connections. Then check the exhaust system for leaks.

REMOVAL AND INSTALLATION

Brackets, clamps and insulators should be replaced if they are damaged or badly corroded. Do not attempt to repair these parts.

INLET PIPE

ECONOLINE AND BRONCO

Removal

If the inlet pipe is being replaced for the first time and it is still welded to the muffler proceed as follows:

1. Raise the vehicle.
2. Loosen the outlet pipe retaining clamp at the rear support bracket (Figs. 1 and 2).
3. Temporarily support the outlet pipe with soft wire.
4. Remove the clamp securing the muffler to the outlet pipe and separate the outlet pipe from the muffler.
5. Disconnect the front support bracket on the inlet pipe.
6. Remove the attaching nuts securing the inlet pipe to the exhaust manifold.
7. Remove the muffler and inlet pipe assembly from the vehicle.
8. Discard the inlet pipe to manifold gasket.

Remove a separate inlet pipe as follows:

1. Raise the vehicle.
2. Remove the attaching nuts securing the inlet pipe to the exhaust manifold.
3. Remove the clamp securing the inlet pipe to the front support bracket.
4. Remove the clamp securing the inlet pipe to the muffler.
5. Temporarily support the muffler and outlet pipe with soft wire.
6. Slide the inlet pipe forward and separate the pipe from the muffler.
7. Discard the gasket.

Installation

If the inlet pipe being replaced was welded to the muffler, first install a replacement muffler as described under Muffler Installation.

1. Clean the gasket surfaces on the inlet pipe flange and exhaust manifold. Position a new gasket on the inlet pipe.
2. Position the inlet pipe to the muffler and loosely install the retaining clamp.
3. Position the inlet pipe in the exhaust manifold and front support bracket.
4. Loosely install the inlet pipe flange and front support bracket clamp.
5. Torque all attaching nuts to the specifications in Part 26-01.
6. Start the engine and check the exhaust system for leaks.
7. Lower the vehicle.

F-100, 250, 350 AND P-SERIES

The typical six cylinder single exhaust systems are shown in Figs. 3, 4 and 5.

Removal

1. Loosen the outlet pipe clamps; then slide the outlet pipe (except cab models) toward the rear.
2. Loosen the inlet pipe and muffler retaining clamp.

Temporarily support the muffler and inlet pipe in position with soft wire.

3. Remove the inlet pipe to manifold attaching nuts; then remove the wire and pull the inlet pipe and muffler assembly away from the manifold. Remove the gasket and inlet pipe.
4. Separate the inlet pipe from the muffler if the muffler is still serviceable. On F-Series trucks, the production muffler and inlet pipe is a one-piece assembly. In service, however, both parts are replaced individually. If the inlet pipe being

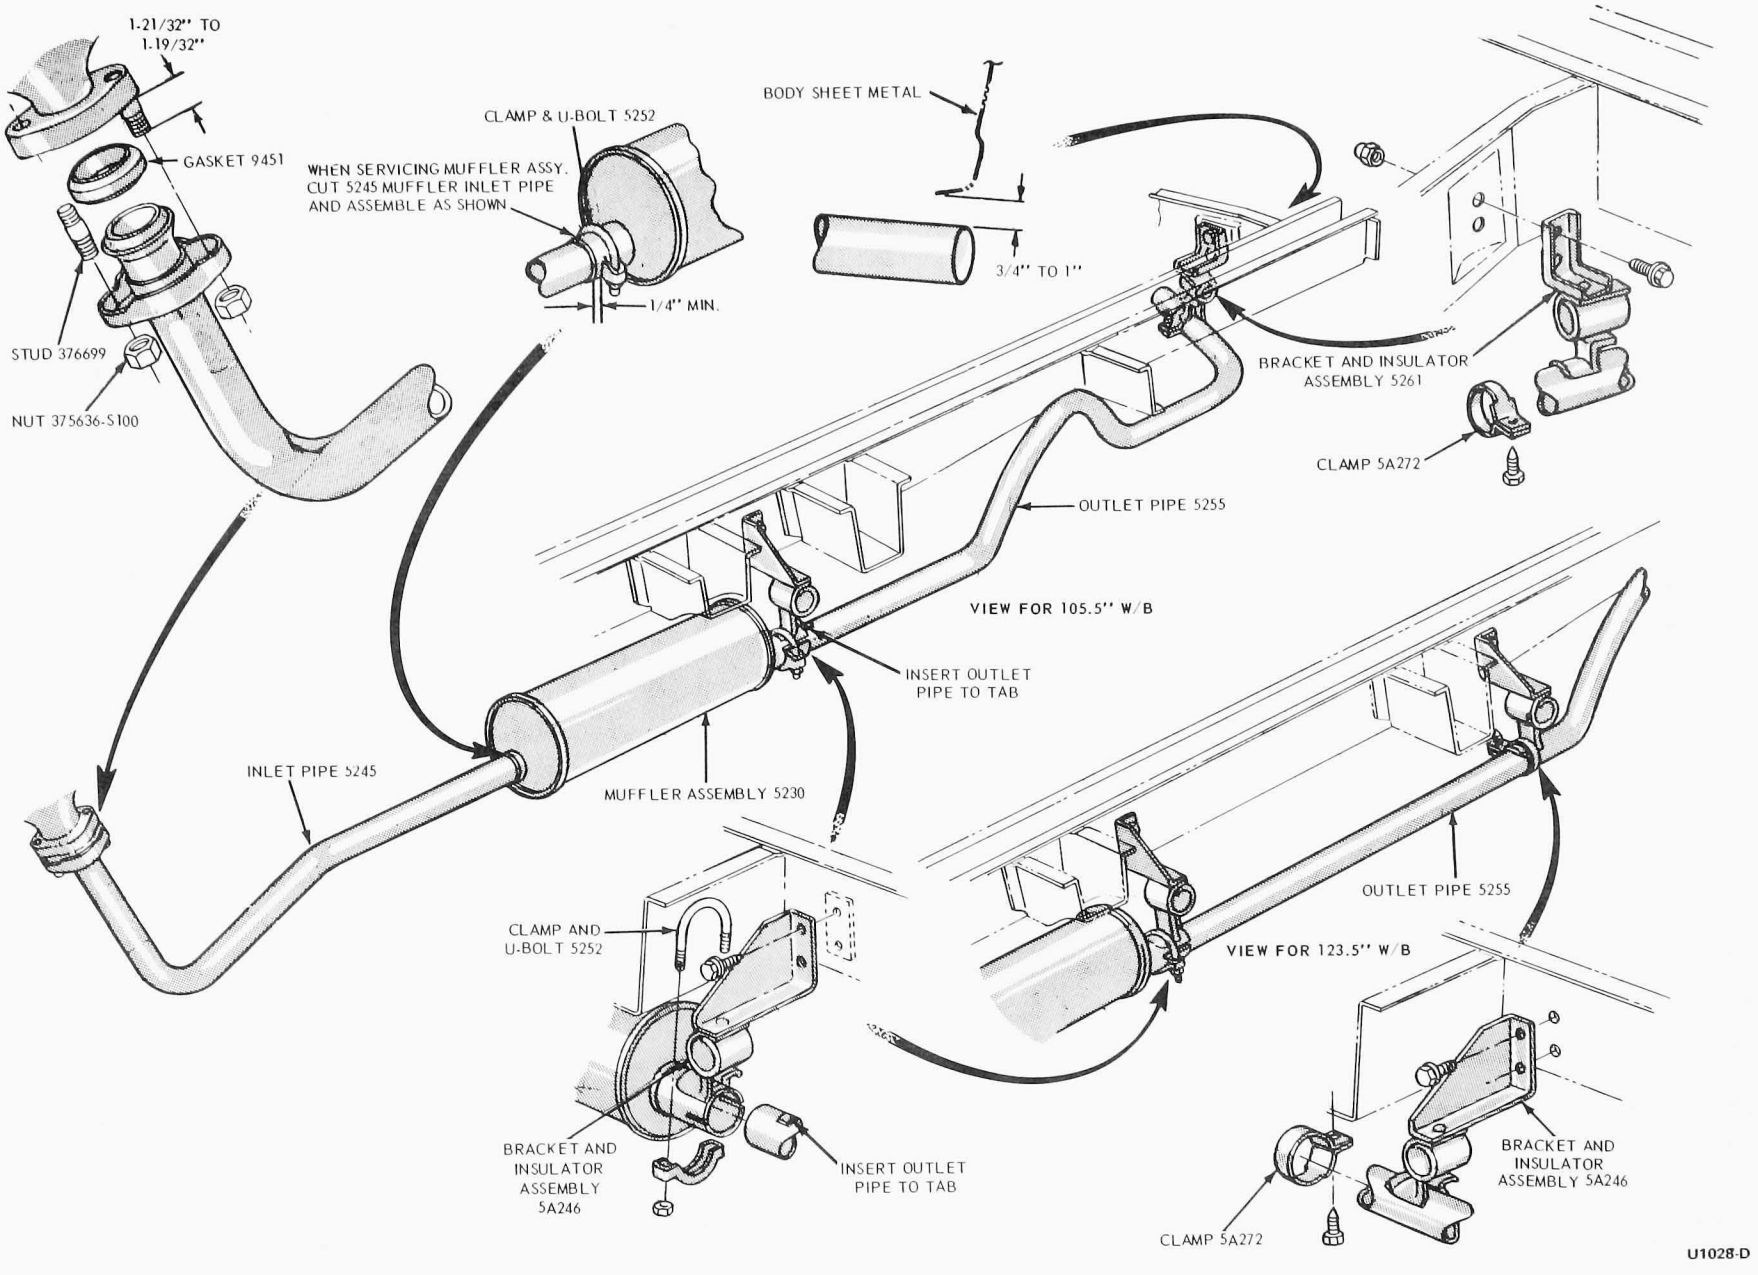

FIG. 1 Econoline Six-Cylinder Exhaust System

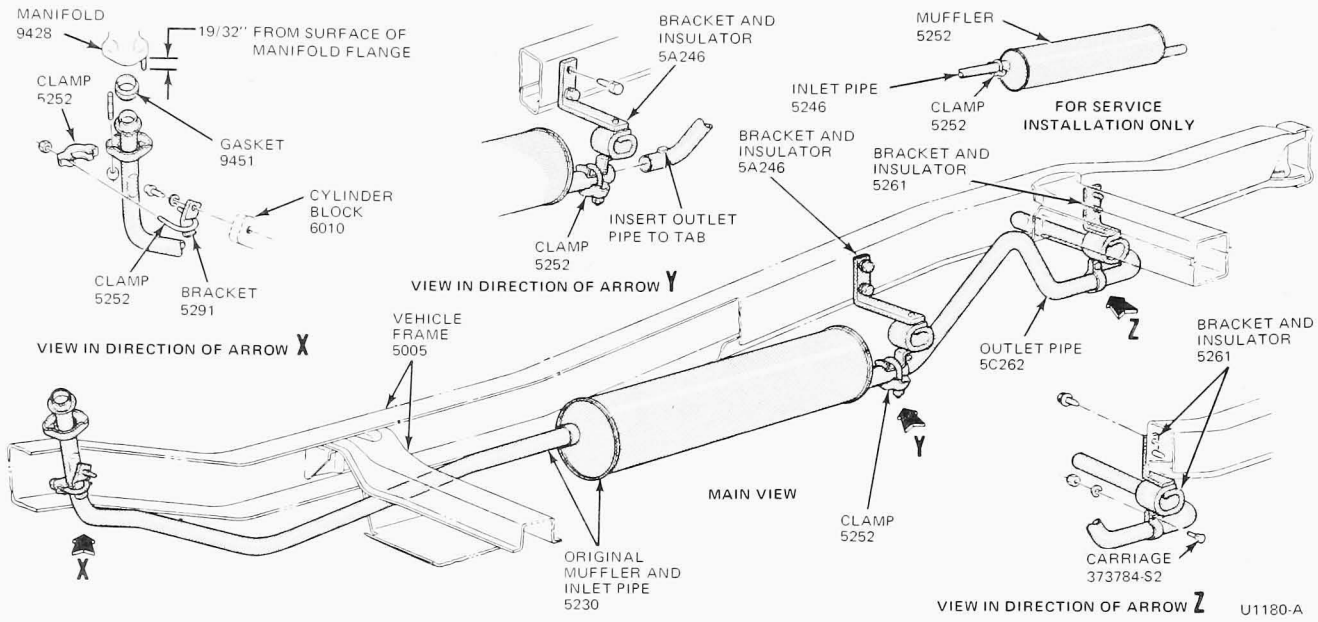

FIG. 2 Bronco Six-Cylinder Exhaust System

replaced still has the welded-on muffler, replace both components.

5. Clean the exhaust manifold flange. Replace any damaged or worn exhaust system parts.

Installation

1. Position the new gasket and inlet pipe to the exhaust manifold. Install the attaching nuts and, alternately and evenly, torque them to specifications.
2. Position the front support bracket and clamp between the inlet pipe and frame side rail. Do not tighten the attaching nuts.
3. Install the inlet pipe to support bracket clamp (if so equipped) and loosely install the attaching nut. On other models support the inlet pipe with soft wire.
4. Position the muffler and outlet pipe in place, loosely installing the clamp(s) attaching nuts.
5. Align the exhaust system and, torque the remaining attaching nuts to the specifications shown in Part 26-01.
6. Check the exhaust system for leaks.

500-750 SERIES TRUCKS

Exhaust systems are shown in Figs. 6, 7, 8 and 9.

Removal

On some trucks the production muffler and inlet pipe (or inlet pipe extension) is a one-piece assembly. In service, however, the parts are replaced individually. If the inlet pipe being replaced still has the welded-on muffler, replace both components.

1. Remove or slide forward the inlet pipe (or extension pipe) to muffler clamp (if so equipped).
2. Separate the inlet pipe and muffler. On some models it may be necessary to loosen the muffler and outlet pipe clamps and slide the muffler rearward to gain clearance for removal.
3. Remove the support bracket clamp securing the inlet pipe to the frame (if so equipped).
4. Remove the inlet-to-inlet pipe extension clamp (if so equipped). Remove the attaching nuts securing the inlet pipe to the exhaust manifold.
5. Remove the inlet pipe from the vehicle.
6. Discard the inlet pipe flange gasket

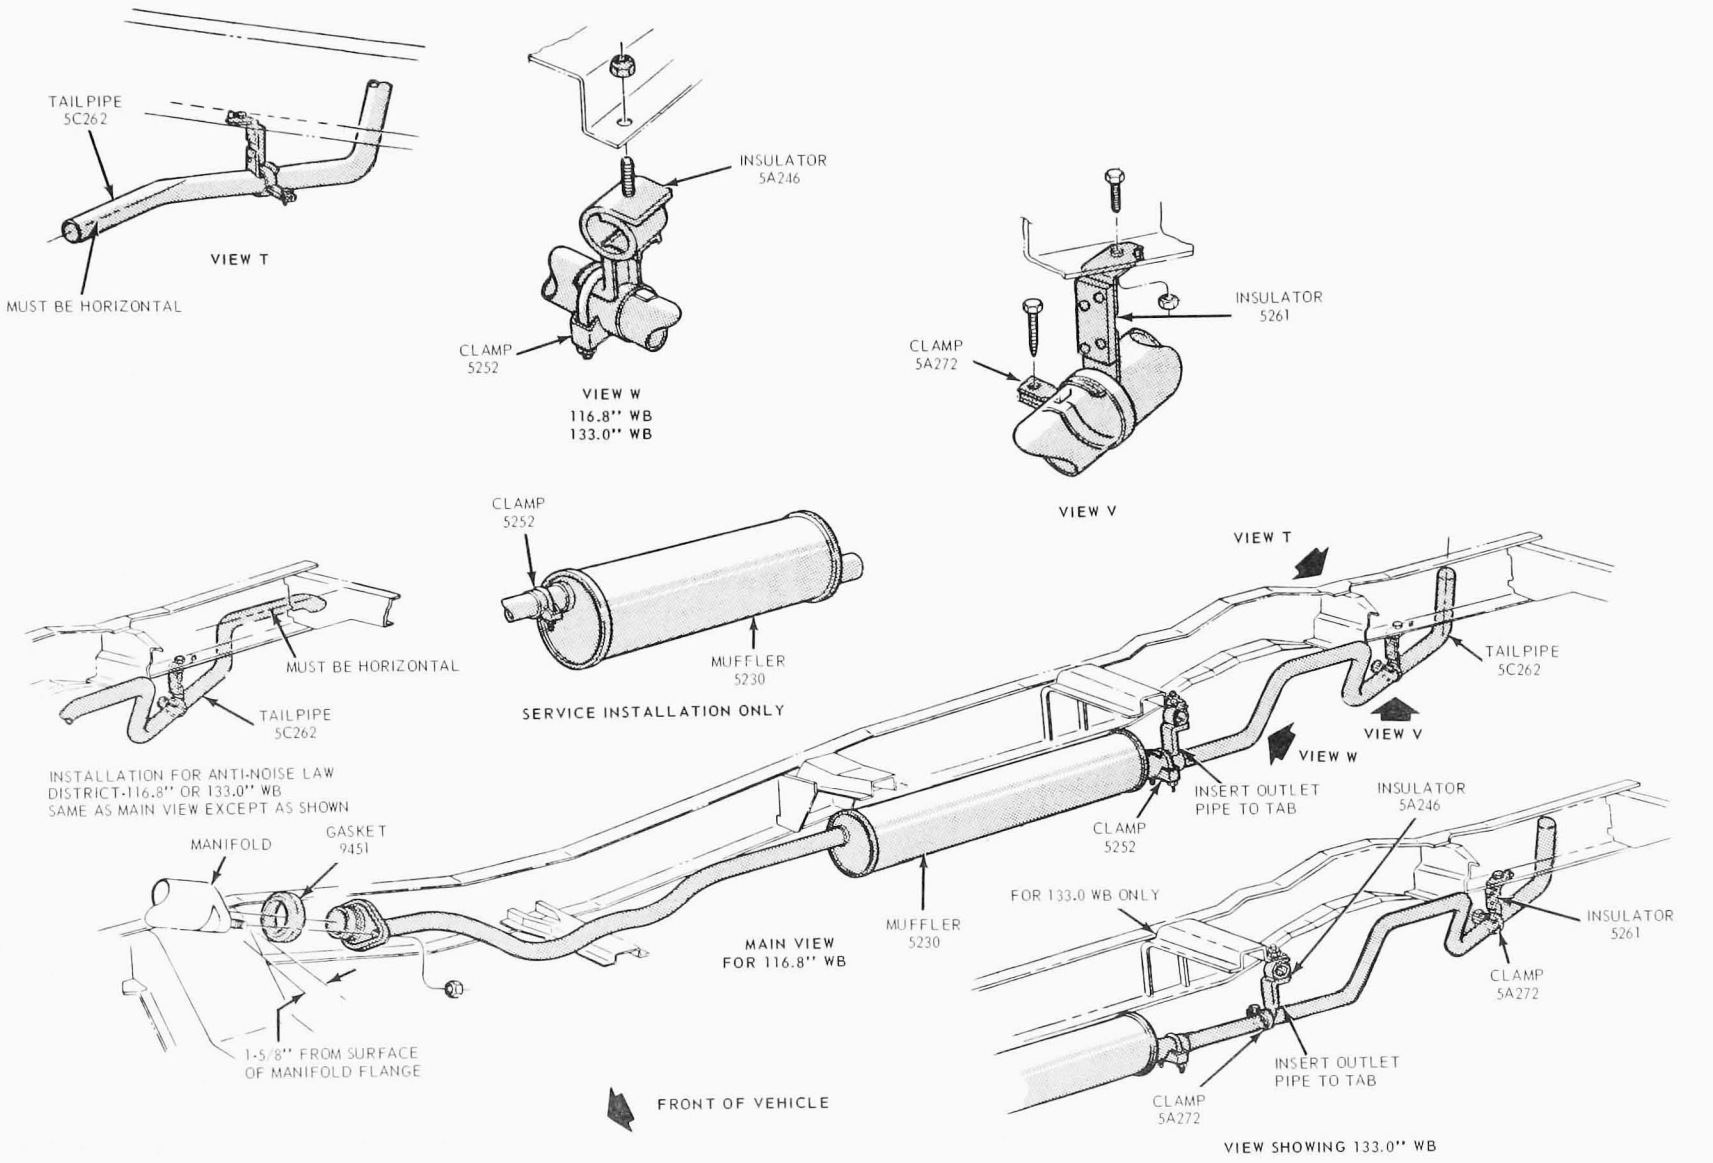

FIG. 3 F-100, 250 Series Six-Cylinder Single Exhaust System

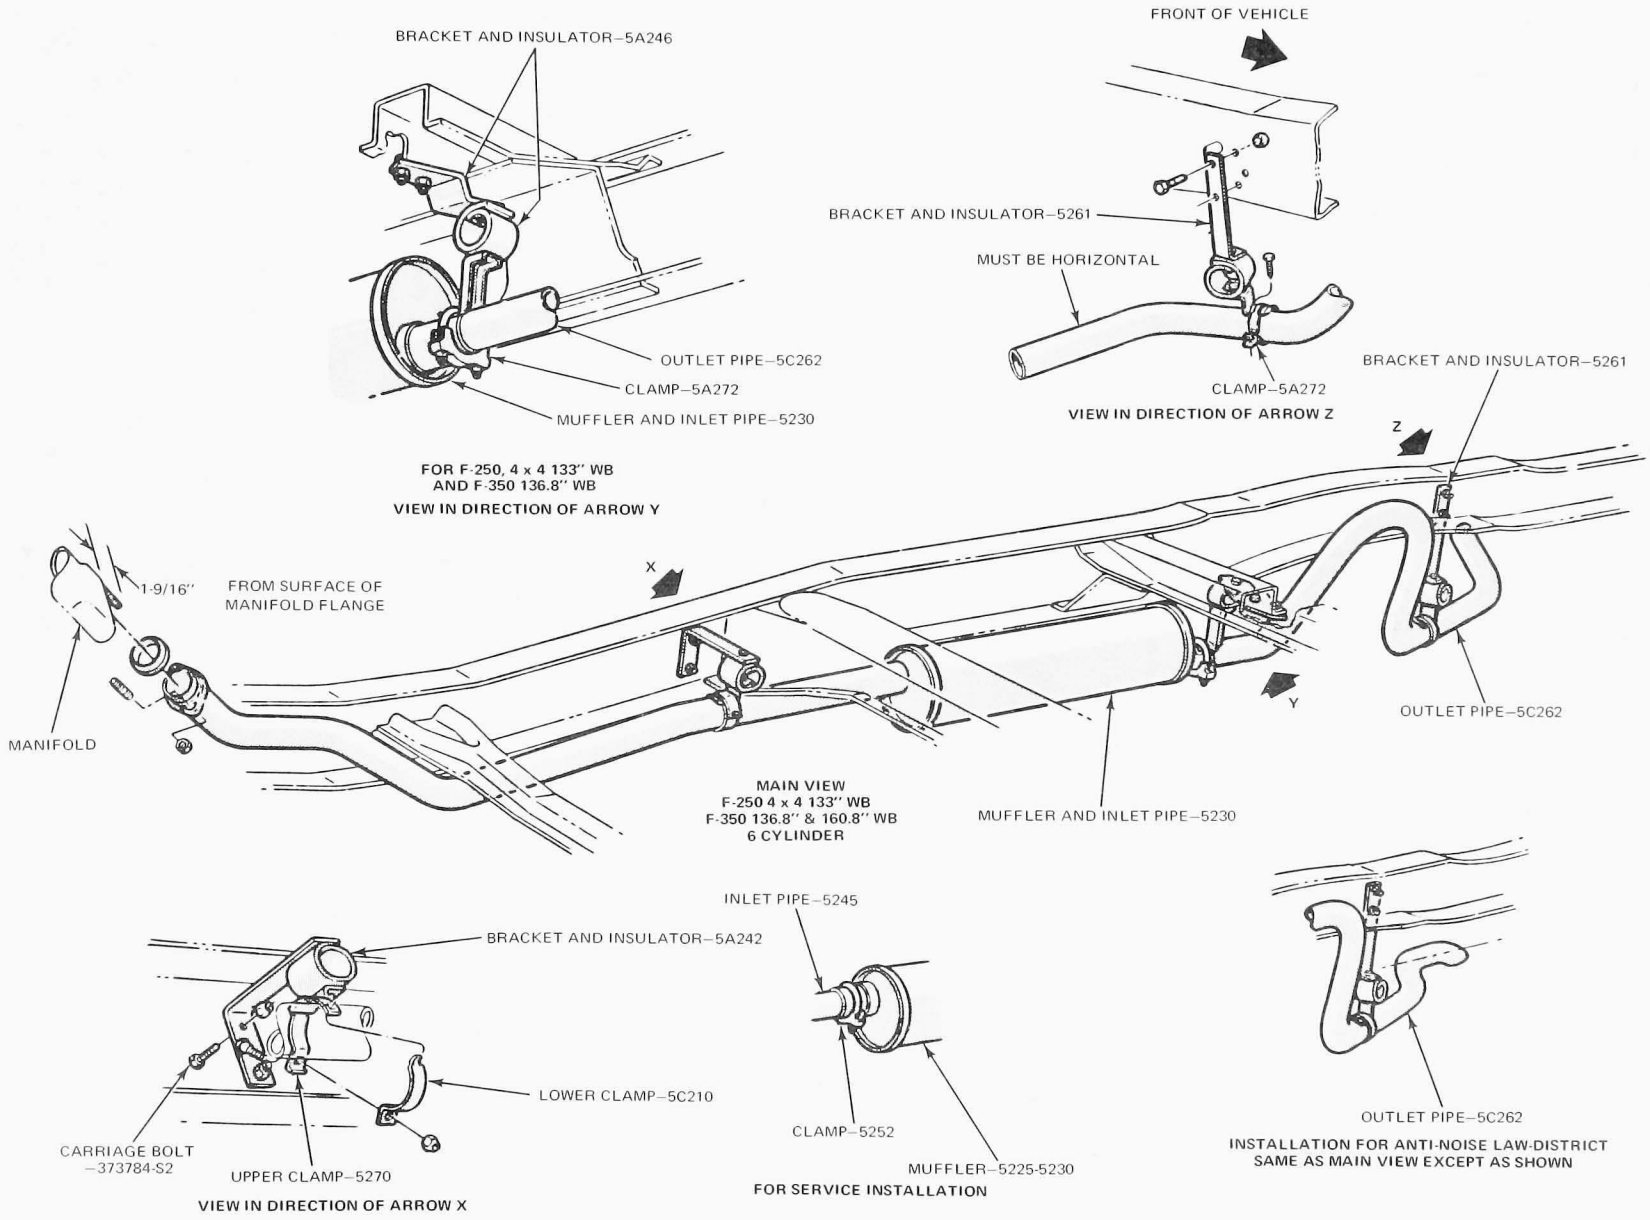

U1179-B

FIG. 4 F-250 (4 x 4) and F-350 Six-Cylinder Single Exhaust System

and clean the exhaust manifold flange.

Installation

1. Position a new service inlet pipe and new gasket on the exhaust manifold and into the muffler. If equipped with an inlet pipe extension, position it between the inlet pipe and muffler.
2. Install the inlet pipe to manifold attaching nuts and tighten alternately and evenly to the torque shown in the specifications in Part 26-01.
3. Install the inlet pipe to muffler clamp and support bracket clamp (if so equipped).
4. Adjust the exhaust system and torque all clamp and bracket attaching nuts to specifications.
5. Check the exhaust system for leaks.

MUFFLER

ECONOLINE AND BRONCO

Removal

1. Raise the vehicle.
2. Loosen the retaining clamp securing the outlet pipe to the rear support bracket (Fig. 1 or 2).
3. Remove the retaining clamp securing the outlet pipe to the muffler.
4. Separate and slide the outlet pipe rearward from the muffler.
5. If the muffler is being replaced for the first time and is welded to the inlet pipe, proceed as follows: support the rear of the muffler. Cut the inlet pipe as close as possible to the muffler. Discard the muffler.
6. Separate the inlet pipe from the muffler and remove the muffler from the vehicle.

Installation

1. Position the muffler to the inlet pipe and loosely install the retaining clamp (Fig. 1 or 2).
2. Position the muffler to the outlet pipe and loosely install the retaining clamp.
3. Adjust the exhaust system and torque the clamp attaching nuts to the specifications shown in Part 26-01.
4. Start the engine and check the system for leaks.
5. Lower the vehicle.

F-100, 250, 350 AND P-SERIES

Removal

1. Remove the muffler to outlet pipe retaining clamp (Fig. 3, 4 or 5). Loosen the outlet pipe retaining clamp(s).
2. Separate the muffler from the outlet pipe and slide the outlet pipe rearward.
3. Remove the inlet pipe to muffler clamp. On F-Series trucks, if the muffler has not been removed previously, cut the inlet flange of the muffler with a hacksaw to separate it from the inlet pipe. **Make the cut as close to the muffler as possible.**
4. Separate the muffler from the inlet pipe and remove it from the vehicle.

Installation

1. Install the retaining clamp on the inlet pipe. Position a new service muffler on the inlet pipe.
2. Position the outlet pipe and clamps on the muffler.
3. Align the exhaust system and tighten the clamps and support clamp bracket attaching nuts to the specification in Part 26-01.
4. Check the exhaust system for leaks.

500-750 SERIES TRUCKS

Removal

1. Remove or slide rearward the muffler to outlet pipe clamp (Fig. 6, 7, 8 or 9).
2. Loosen the other outlet pipe clamps.
3. Separate the muffler from the outlet pipe.
4. Remove the inlet pipe to muffler clamp and separate the muffler from the pipe. For initial replacement on a truck with a one-piece muffler inlet pipe, cut the inlet flange of the muffler with a hacksaw and remove the muffler. **Make the cut as close to the muffler as possible.**

Installation

1. Install the retaining clamp(s) on the inlet pipe. Position a new service muffler on the inlet pipe.
2. Position the outlet pipe and clamp on the muffler.
3. Align the exhaust system and tighten the clamps and support clamp bracket attaching nuts to the specifications in Part 26-01.

OUTLET PIPE

ECONOLINE AND BRONCO

Removal

1. Raise the vehicle.
2. Remove the clamps securing the outlet pipe to the muffler and support brackets (Fig. 1 or 2).
3. Separate the outlet pipe from the muffler and remove from the vehicle.

Installation

1. Position the outlet pipe to the muffler and support bracket at the rear of the vehicle and approximately 1 1/4 inches below the body sheet metal (also the intermediate support bracket on the Econoline Supervan models).
2. Install the retaining clamps to hold the outlet pipe in position.
3. Align the system and torque the retaining clamp nuts to the specifications shown in Part 26-01.
4. Start the engine and check the exhaust system for leaks.
5. Lower the vehicle.

F-100, 250, 350 AND P-SERIES

Removal

1. Remove the outlet pipe clamp at the muffler (Fig. 3, 4 or 5). Remove the outlet pipe support bracket clamps (if so equipped). Separate the outlet pipe from the muffler.
2. Replace any damaged or worn parts.

Installation

1. Position the muffler clamp on the new outlet pipe, then slide the pipe on the muffler. Install, but do not tighten, the support clamps (if so equipped).
2. Adjust the exhaust system and tighten the outlet pipe clamp and support bracket clamp attaching nuts to the specifications in Part 26-01 (if so equipped).
3. Check the exhaust system for leaks.

500-750 SERIES TRUCKS

Removal

1. Remove or loosen and slide rearward the outlet pipe clamp at the muffler (Fig. 6, 7, 8 or 9). Remove the outlet pipe support bracket clamps (if so equipped). Separate the outlet pipe from the muffler.

   If the truck is equipped with a muffler outlet pipe extension, loosen the retaining clamp(s) and remove from the outlet pipe.
2. Replace any damaged or worn parts.

Installation

1. Position the muffler clamp on the outlet pipe, then slide the pipe onto the muffler. Install, but do not tighten, the support clamps (if so equipped).

   If the truck is equipped with a muffler outlet pipe extension, position the retaining clamp on the outlet pipe. Slide the pipe extension onto the outlet pipe and tighten the retaining clamp.
2. Align the exhaust system and tighten the outlet pipe clamp and support bracket clamp attaching nuts (if so equipped) to the specifications in Part 26-01.
3. Check the exhaust system for leaks.

Brackets, clamps and insulators should be replaced if they are damaged or badly corroded. Do not attempt to repair these parts.

INLET PIPE—EIGHT-CYLINDER BRONCO MODELS

Removal

If the inlet pipe is being replaced for the first time and is still welded to the muffler proceed as follows:

1. Remove the attaching nuts securing the inlet pipe to the exhaust manifold.
2. Loosen the outlet pipe retaining clamp at the rear support bracket (Fig. 1).
3. Temporarily support the outlet pipe with soft wire.
4. Remove the clamp securing the muffler to the outlet pipe and separate the outlet pipe from the muffler.
5. Remove the attaching nuts securing the inlet pipe and crossover pipe to the exhaust manifolds.
6. Remove the muffler and inlet pipe assembly from the vehicle.
7. Discard the inlet pipe and crossover pipe to manifold gaskets.

Installation

If the inlet pipe being replaced was welded to the muffler, first install a replacement muffler as described under Muffler Installation.

1. Clean the gasket surfaces on the exhaust manifolds and the inlet pipe flanges.
2. Position new gaskets on the inlet pipe flanges.
3. Position the inlet pipe to the exhaust manifolds and loosely install the attaching nuts.
4. Slip the front end of the muffler into place over the inlet pipe and install but, do not tighten the clamp.
5. Slip the outlet pipe into place on the muffler and install the clamp.
6. Align the exhaust system then, tighten all attaching nuts to the specifications shown in Part 26-01.
7. Start the engine and check the exhaust system for leaks.
8. Lower the vehicle.

INLET PIPE—EIGHT-CYLINDER ECONOLINE MODELS

Removal

1. Raise the vehicle.
2. Loosen the clamps securing the muffler and outlet pipe to the support brackets (Fig. 2).
3. Remove the clamp securing the inlet pipe to the muffler.
4. Separate the inlet pipe from the muffler and slide the outlet pipe and muffler rearward.
5. Disconnect and remove the inlet pipe from the exhaust manifolds.

Installation

1. Clean the inlet pipe flanges on the exhaust manifold.
2. Place new gaskets on the inlet pipe flanges. Position the inlet pipe in the muffler and on the exhaust manifolds.
3. Loosely install the exhaust manifold to inlet pipe attaching nuts.
4. Align the exhaust system and torque all attaching nuts to the specifications in Part 26-01.
5. Start the engine and check the exhaust system for leaks.
6. Lower the vehicle.

MUFFLER—BRONCO AND ECONOLINE

Removal

1. Raise the vehicle.
2. Loosen the retaining clamp(s) securing the outlet pipe to the rear support bracket(s) (Figs. 1 or 2).
3. Remove the retaining clamp securing the outlet pipe to the muffler.
4. Separate and slide the outlet pipe rearward from the muffler.
5. Remove the clamp securing the inlet pipe to the muffler.
6. Separate the inlet pipe from the muffler and remove the muffler from the vehicle.

Installation

1. Position the muffler to the inlet pipe and loosely install the retaining clamp.
2. Position the muffler to the outlet pipe and loosely install the retaining clamp.
3. Align the exhaust system and torque the clamp attaching nuts to the specifications shown in Part 25-01.
4. Start the engine and check the system for leaks.
5. Lower the vehicle.

OUTLET PIPE-BRONCO AND ECONOLINE

Removal

1. Raise the vehicle.
2. Remove the clamps securing the outlet pipe to the muffler and support brackets (Figs. 1 or 2).
3. Separate the outlet pipe from the muffler and remove from the vehicle.

Installation

1. Position the outlet pipe to the muffler and support bracket at the rear of the vehicle and approximately 1 1/4 inches below the body sheet metal. (Also the intermediate support bracket on the Econoline Supervan models).
2. Install the retaining clamps to hold the outlet pipe in position.
3. Align the system and torque the retaining clamp nuts to the specifications shown in Part 26-01.
4. Start the engine and check the exhaust system for leaks.
5. Lower the vehicle.

EXHAUST SYSTEM—F-100, 250-, 350

The typical exhaust systems are shown in Figs. 3 and 4.

The following procedures apply to 8-cylinder engine single exhaust systems.

INLET PIPE

Removal

1. Loosen the outlet pipe clamps; then, slide the outlet pipe (all except cab models) toward the rear.
2. Temporarily support the muffler and inlet pipe in position with soft wire.
3. Remove the inlet pipe to manifold attaching nuts; then, remove the wire and pull the inlet pipe and muffler assembly away from the manifolds. Remove the flange gaskets.
4. Separate the inlet pipe from the muffler if the muffler is still serviceable. On F-Series trucks the production muffler and inlet pipe is a one-piece assembly. In service however, both parts are replaced individually. If the inlet pipe being replaced still has the welded on muffler, replace both components.
5. Clean the exhaust manifold flanges. Remove any damaged or worn exhaust system parts.

Installation

1. Position the new gaskets and inlet pipe and cross-over pipe on the exhaust manifolds. Install the attaching nuts and alternately and evenly torque to specifications in Part 26-01.
2. Position the front support bracket and clamp between the inlet pipe and frame side rail. Do not tighten the attaching nuts.
3. Install the inlet pipe to support bracket clamp (if so equipped) and loosely install the attaching nut. On other models support the inlet pipe with soft wire.
4. Position the muffler and outlet pipe in place, loosely installing the clamp(s) attaching nuts.
5. Align the exhaust system and, torque the remaining attaching nuts to the specifications in Part 25-01.
6. Check the exhaust system for leaks.

MUFFLER

Removal

1. Remove the muffler to outlet pipe retaining clamp (Figs. 3 or 4). Loosen the outlet pipe retaining clamp(s).
2. Separate the muffler from the outlet pipe and slide the outlet pipe rearward.
3. Remove the inlet pipe to muffler clamp. On F-Series trucks if the original muffler has not been removed, cut the inlet flange of the muffler with a hacksaw to separate it from the inlet pipe. **Make the cut as close to the muffler as possible.**

Separate the muffler from the inlet pipe and remove from the vehicle.

Installation

1. Install the retaining clamp on the inlet pipe. Position a new service muffler on the inlet pipe.
2. Position the outlet pipe and clamps on the muffler.
3. Align the exhaust system and tighten the clamps and support clamp bracket attaching nuts to the specification in Part 26-01.
4. Check the exhaust system for leaks.

OUTLET PIPE

Removal

1. Remove the outlet pipe clamp at the muffler (Figs. 3 or 4). Remove the outlet pipe support bracket clamps (if so equipped). Separate the outlet pipe from the muffler.
2. Replace any badly damaged or worn parts.

Installation

1. Position the muffler clamp on the new outlet pipe, then slide the pipe on the muffler. Install, but do not tighten, the support clamps (if so equipped).
2. Align the exhaust system and tighten the outlet pipe clamp and support bracket clamp attaching nuts to the specifications in Part 26-01 (if so equipped).
3. Check the exhaust system for leaks.

EXHAUST SYSTEM—500-900 SERIES TRUCKS

Typical V-8 single exhaust systems are shown in Figs. 5 thru 8.

INLET PIPE

Removal

On some trucks the production muffler and inlet pipe (or inlet pipe extension) is a one-piece assembly. In service, however, both parts are replaced individually. If the inlet pipe being replaced still has the welded-on muffler, replace both components.

1. Remove or slide forward the inlet pipe (or extension pipe) to muffler clamp (if so equipped).
2. Separate the inlet pipe and muffler. On some models it may be necessary to loosen the muffler and outlet pipe clamps and slide the muffler rearward to gain removal clearance.
3. Remove the support bracket clamp(s) securing the inlet pipe to the frame (if so equipped).
4. Remove the inlet-to-inlet pipe extension clamp (if so equipped). Remove the attaching nuts securing the inlet pipe to the exhaust manifolds.
5. Remove the inlet pipe from the vehicle.
6. Remove the inlet pipe flange gaskets and clean the exhaust manifold flanges.

Installation

1. Position a new service inlet pipe and new gaskets on the exhaust manifolds and into the muffler. If equipped with an inlet pipe extension, position it between the inlet pipe and muffler.
2. Install the inlet pipe to manifold attaching nuts and tighten alternately and evenly to the torque shown in the specifications in Part 26-01.
3. Install the inlet pipe to muffler clamp and support bracket clamp(s) (if so equipped).
4. Adjust the exhaust system and torque all clamp and bracket attaching nuts to specifications.
5. Check the exhaust system for leaks.

MUFFLER

Removal

1. Remove or slide the muffler to outlet pipe clamp rearward (Figs. 5 thru 8).
2. Loosen the other outlet pipe clamps.
3. Separate the muffler from the outlet pipe.
4. Remove the inlet pipe to muffler clamp and separate the muffler from the pipe. For initial replacement on the truck with a one-piece muffler inlet pipe cut the inlet flange of the muffler with a hacksaw and remove the muffler. **Make the cut as close to the muffler as possible.**

Installation

1. Install the retaining clamp(s) on the inlet pipe. Position a new service muffler on the inlet pipe.
2. Position the outlet pipe and clamp on the muffler.
3. Adjust the exhaust system and tighten the clamps and support clamp bracket attaching nuts to the specifications in Part 26-01.

OUTLET PIPE

Removal

1. Remove or loosen and slide the outlet pipe clamp rearward at the muffler (Figs. 5 thru 8). Remove the outlet pipe support bracket clamps (if so equipped). Separate the outlet pipe from the muffler.

If the truck is equipped with a muffler outlet pipe extension, loosen the

retaining clamp(s) and remove it from the outlet pipe.
2. Replace any damaged parts.

Installation

1. Position the muffler clamp on the outlet pipe, then slide the pipe onto the muffler. Install, but do not tighten, the support clamps (if so equipped).

If the truck is equipped with a muffler outlet pipe extension, position the retaining clamp on the outlet pipe. Slide the pipe extension onto the outlet pipe and tighten the retaining clamp.

2. Align the exhaust system and tighten the outlet pipe clamp and support bracket clamp attaching nuts (if so equipped) to the specifications in Part 26-01.
3. Check the exhaust system for leaks.

REMOVAL AND INSTALLATION

Brackets, clamps and insulators should be replaced if they are damaged or badly corroded. Do not attempt to repair these parts.

EXHAUST SYSTEMS—600-1000 SERIES TRUCKS

Typical V-8 dual exhaust systems are shown in Figs. 1 thru 6.

The following procedures apply to the right or left installation for the dual exhaust system, unless otherwise noted.

INLET PIPE

Removal

1. Remove the clamp securing the inlet pipe to the muffler.
2. Remove the attaching nuts securing the inlet pipe to the exhaust manifold.
3. Separate the inlet pipe from the exhaust manifold and the muffler.
4. Remove the flange gasket and clean the exhaust manifold flange(s).

Installation

1. Position the inlet pipe in the muffler. Loosely install the retaining clamp.
2. Place a new gasket on the exhaust manifold flange and position the inlet pipe to the exhaust manifold. Loosely install the attaching nuts.
3. Adjust the system. Torque all attaching nuts and bolts to specifications in Part 26-01.
4. Check the system for leaks.

MUFFLER

Removal

1. Remove the retaining clamp securing the muffler to the outlet pipe and separate the outlet pipe from the muffler (Figs. 1 thru 6).
2. Remove the clamp securing the muffler to the inlet pipe.
3. Loosen the muffler support bracket clamps.
4. Separate the muffler from the inlet pipe and remove it from the vehicle.

Installation

1. Slide the muffler through the retaining clamps and position it on the inlet pipe. Loosely install the retaining clamp.
2. Position the outlet pipe to the muffler and loosely install the retaining clamp.
3. Adjust the system and torque the attaching nuts and bolts to the specifications in Part 26-01.
4. Check the system for leaks.

OUTLET PIPE

Removal

1. Remove the clamp securing the outlet pipe to the muffler (Figs. 1 thru 6).
2. Remove the outlet pipe.

Installation

1. Position the outlet pipe to the muffler and loosely install the retaining clamp(s).
2. Adjust the position of the outlet pipe and torque the attaching nuts to the specifications in Part 26-01.
3. Check the system for leaks.

COMPONENT INDEX	Page	COMPONENT INDEX	Page
INLET PIPE		MUFFLER AND OUTLET PIPE	
Installation	30-01	Installation	30-01
Removal	30-01	Removal	30-01
		SPECIFICATIONS	01-02

REMOVAL AND INSTALLATION

Brackets, clamps and insulators should be replaced if they are damaged or badly corroded. Do not attempt to repair these parts.

INLET PIPE

C-, L-AND LN-6000-8000 CAB MODELS AND LT-, LTS-, LNT-8000

The exhaust systems for the Ford V-8 diesel engines are shown in Figs. 1 thru 7.

Removal

1. Loosen the hanger straps on the muffler.
2. Remove the inlet pipe extension to muffler clamp, separate the extension from the muffler, and slide the muffler rearward.
3. Remove the exhaust manifold to inlet pipe nuts and bolts and remove the inlet pipe assembly from the vehicle.
4. Remove the right and left inlet pipe to extension clamps. Separate the pipes from the adapter.
5. Clean the exhaust manifold flanges.

Installation

1. Position the right and left inlet pipes in the extension. Loosely install the retaining clamps.
2. Position the inlet pipe assembly on the exhaust manifold flanges and into the muffler. Loosely install the pipe to manifolds nuts and bolts and muffler clamp.
3. Align the exhaust system and tighten all attaching nuts to the specifications in Part 26-01.
4. Check the system for leaks.

L-AND B-6000-7000 COWL MODELS

Removal

1. Remove the bolts and nuts securing the inlet pipes to the exhaust manifolds.
2. Remove the clamp securing the inlet pipe extension to the muffler and separate the extension from the muffler.
3. Loosen the muffler hanger straps and outlet pipe clamps as necessary to provide lowering clearance to disengage the inlet pipes from the exhaust manifolds.
4. Remove the clamps and separate the right and left inlet pipes from the extension.
5. Clean the exhaust manifold flanges.

Installation

1. Position the left and right inlet pipes in the inlet pipe extension and loosely install the retaining clamps.
2. Position the extension in the muffler and the inlet pipes in the exhaust manifolds. Loosely install the attaching nuts, bolts and clamps,
3. Adjust the exhaust system and torque all the nuts to the specifications in Part 26-01.
4. Check the exhaust system for leaks.

MUFFLER AND OUTLET PIPE

C-, L-AND LN 6000-8000 CAB MODELS AND LT-, LTS-, LNT-8000

Removal

1. Loosen the muffler hanger strap retaining nuts (Figs. 1 and 2).
2. Remove the muffler to inlet pipe extension clamp and separate the muffler from the extension.
3. Remove the hanger strap attaching nuts and remove the muffler.
4. Remove the outlet pipe to muffler clamp and separate the pipe.

Installation

1. Position the outlet pipe in the muffler and loosely install the clamp.
2. Position the muffler on the inlet pipe extension, place the muffler hanger straps in position and loosely install the attaching nuts.
3. Loosely install the muffler to inlet pipe adapter clamp.
4. Adjust the exhaust system and tighten all nuts to the specifications in Part 26-01.
5. Check the system for leaks.

L AND B-6000-7000 COWL MODELS

Removal

1. Perform steps 1 through 3 for inlet pipe removal.
2. Remove the clamp securing the outlet pipe to the muffler and separate the pipe from the muffler (Figs. 5 and 6).
3. Remove the muffler hanger strap nuts and lower the muffler.
4. Remove the outlet pipe extension support bracket clamp(s) and separate the outlet pipe extension from the rear outlet pipe (Figs. 5 and 6).
5. Remove the rear outlet pipe support bracket clamps. On L-6000-7000 174 inch wheelbase models, remove the outlet pipe to rear outlet pipe clamp. Separate the rear outlet pipe from the outlet pipe.
6. Remove the outlet pipe support bracket clamp(s).
7. Remove the heat shield from outlet pipe.

Installation

1. Position the muffler on the outlet pipe and install the muffler hanger straps.
2. Loosely install the muffler to the outlet pipe clamp.
3. Position the inlet pipe assembly in the muffler and to the exhaust manifold. Loosely install the attaching nuts, bolts and clamp.
4. Progressively place the outlet pipe, rear outlet pipe and outlet pipe extension in position, loosely installing the retaining clamps as the parts are installed.
5. Align the pipes and torque the clamp nuts to the specifications in Part 26-01.

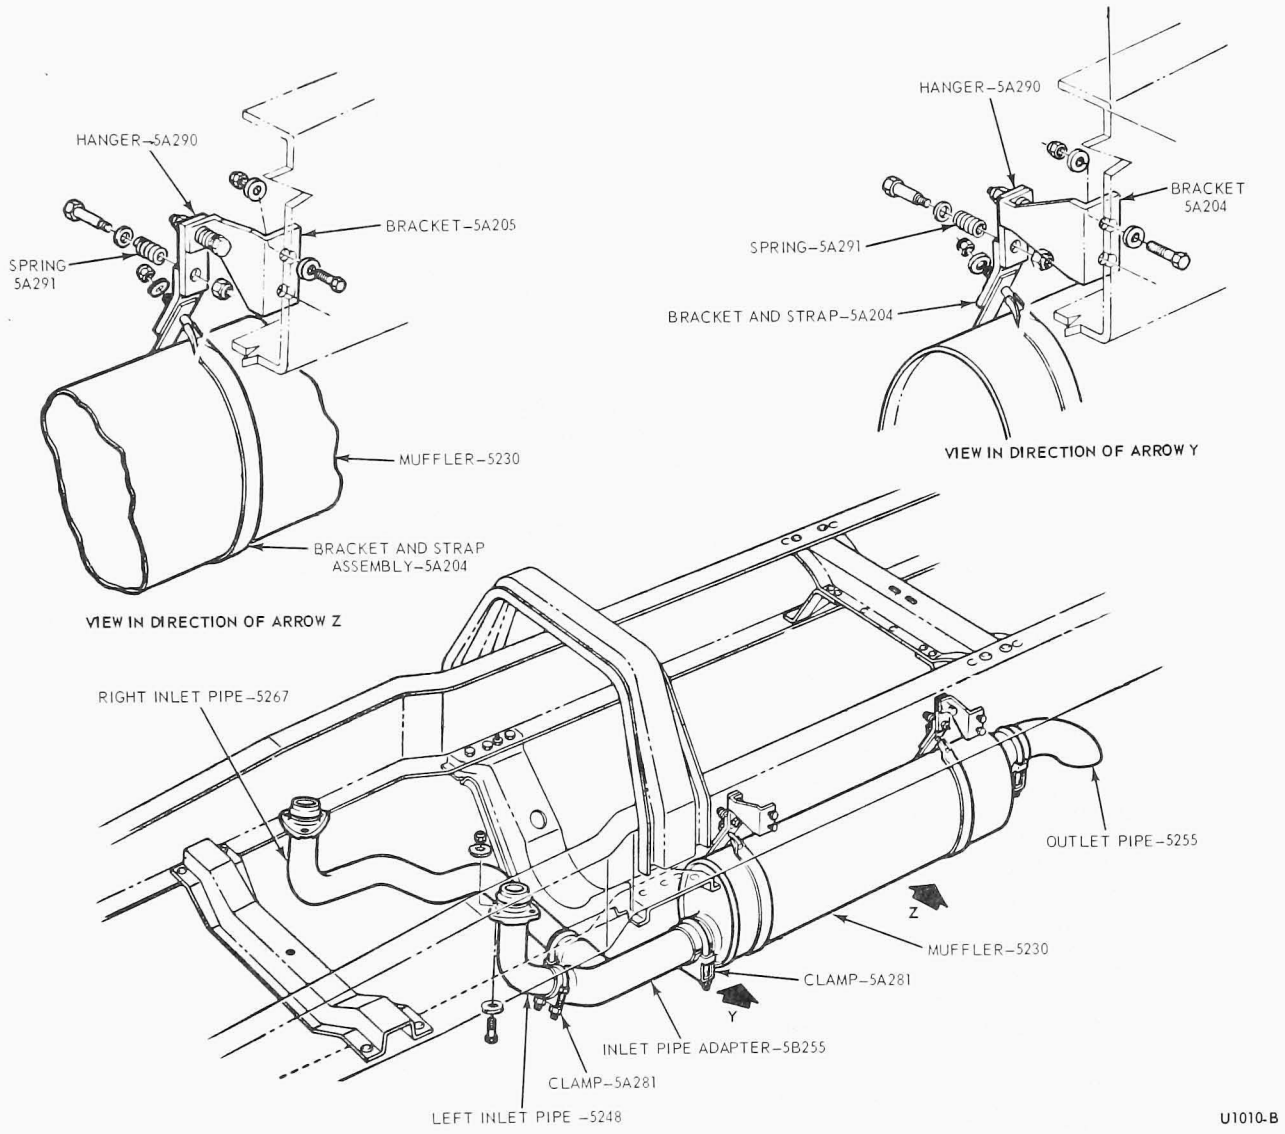

FIG. 1 Exhaust System—C-6000-8000 Ford V-8 Diesel

6. Install the heat shield on the outlet pipe under the air tank. Position the shield as shown in Fig. 5.
7. Check the system for leaks.

REMOVAL AND INSTALLATION

Brackets, clamps and insulators should be replaced if they are damaged or badly corroded. Do not attempt to repair these parts.

EXHAUST SYSTEM L, LT AND LNT-8000-9000 AND LN-9000 TRUCKS

MUFFLER INLET FRONT PIPE

Removal

1. Loosen the retaining clamps securing the front and rear inlet pipes to the flex connector (Figs. 1 thru 5).
2. Remove the front inlet pipe to manifold attaching nuts. Slide the flex connector rearward and disconnect it from the front inlet pipe. Remove the inlet pipe and gasket from the exhaust manifold.
3. Clean the gasket mounting surface on the exhaust manifold and inlet pipe.

Installation

1. Position a new gasket and the inlet pipe on the exhaust manifold. Install and tighten the inlet pipe attaching nuts.
2. Place the front retaining clamp on the flex connector and slide the connector forward onto the front inlet pipe. Properly position the connector and front clamp; then, tighten the front and rear clamps to the specifications in Part 26-01.
3. Check the exhaust system for leaks.

MUFFLER INLET REAR PIPE AND FLEX CONNECTOR

Removal

1. Loosen the flex connector retaining clamps and slide the flex connector rearward (Figs. 2 thru 5).
2. Loosen the rear inlet pipe clamp at the muffler and remove the inlet pipe and flex connector. Separate the connector and inlet pipe.

Installation

1. Connect the rear inlet pipe to the flex connector, and position the rear inlet pipe to muffler clamp on the inlet pipe. Insert the flex connector through the inlet pipe support bracket clamp. Place the connector to front inlet pipe clamp on the connector.
2. Connect the rear inlet pipe and flex connector assembly to the muffler and inlet front pipe. Properly position the inlet rear pipe, flex connector and the retaining clamps. Tighten the retaining clamps to specifications (Part 26-01).
3. Check the exhaust system for leaks.

EXHAUST SYSTEM—W-AND WT-SERIES TRUCKS

Typical exhaust systems used on the W-Series truck are shown in Fig. 6.

INLET PIPE—CUMMINS NH ENGINES

Removal

1. Loosen the inlet pipe to inlet pipe extension clamp (Fig. 6).
2. Remove the exhaust manifold to inlet pipe bolts and nuts.
3. Remove the inlet pipe bracket clamp.
4. Remove the inlet pipe and clean the gasket surfaces.

Installation

1. Using a new gasket place the new inlet pipe in position and install the exhaust manifold to inlet pipe bolts and nuts.
2. Install the inlet pipe bracket clamp.
3. Tighten the inlet pipe to inlet pipe extension clamp to specifications.

INLET PIPE—CUMMINS NTC ENGINE

Removal

1. Remove the inlet pipe to engine and inlet pipe to inlet pipe extension clamps.
2. Remove the support bracket clamps on the inlet pipe and inlet pipe extension.
3. Separate and remove the inlet pipe from the inlet pipe extension.
4. Clean inlet pipe mounting flange of the exhaust manifold.

Installation

1. Place the new inlet pipe in position and loosely install the retaining clamps at both ends.
2. Install the support bracket clamps on the inlet pipe and inlet pipe extension.
3. Properly position the inlet pipe and support brackets and tighten all clamps and nuts to specifications (Part 26-01).

4. Check the exhaust system for leaks.

INLET PIPE EXTENSIONS

Removal

1. Loosen the inlet pipe extension to muffler clamp (Fig. 6).
2. Loosen the inlet pipe or inlet pipe adaptor to inlet pipe extension clamp and slide it onto the inlet pipe or inlet pipe adaptor.
3. Disconnect the inlet pipe extension support bracket from the inlet pipe extension clamp.
4. Remove the inlet pipe extensions from the vehicle.
5. Remove the clamp retaining the flex tube to the inlet pipe extension and separate the two inlet pipe extensions.

Installation

1. Extend the flex pipe to 15 1/2 inches. Position the flex pipe to the inlet pipe extension and install the clamp (Fig. 6).
2. Position the inlet pipe extensions to the inlet pipe and muffler.
3. Position the inlet pipe to inlet pipe extension and inlet pipe extension to muffler clamps.
4. Connect the inlet pipe extension support bracket to the clamp retaining the two inlet pipe extensions together.
5. Tighten all clamps to specifications (Part 26-01).

MUFFLER

Removal

1. Remove the two muffler retaining clamps (Fig. 6).
2. Remove the muffler and outlet pipe from the inlet pipe extension.
3. Remove the outlet pipe from the muffler.

Installation

1. Place the outlet pipe on the new muffler.
2. Place the outlet pipe and muffler assembly on the inlet pipe extension and loosely install the two muffler retaining clamps.
3. Position the outlet of the pipe towards the right hand curb.
4. Tighten the muffler clamps to specification (Part 26-01).
5. Check the exhaust system for leaks.

MUFFLER OUTLET PIPE

Removal

1. Remove the muffler to outlet pipe clamp.
2. Remove the outlet pipe and rain cap.

Installation

1. Place a new outlet pipe in position. The pipe outlet should be towards the right hand curb.
2. Install and tighten the muffler to outlet pipe clamp to specifications (Part 26-01).
3. Install the rain cap as shown in Fig. 6.
4. Check the exhaust system for leaks.

REMOVAL AND INSTALLATION

Brackets, clamps and insulators should be replaced if they are damaged or badly corroded. Do not attempt to repair these parts.

Typical exhaust systems are shown in Figs. 1 thru 6.

The following procedures apply to the right or left installation for the dual exhaust system, unless otherwise noted.

INLET PIPE LN-AND LT-8000-SERIES

Removal

1. Remove the clamp securing the inlet pipe to the muffler.
2. Remove the attaching nuts securing the inlet pipe to the exhaust manifold.
3. Separate the inlet pipe from the exhaust manifold and the muffler.
4. Remove the mounting gasket and clean the exhaust manifold flange(s).

Installation

1. Position the inlet pipe in the muffler. Loosely install the retaining clamp.
2. Place a new gasket on the exhaust manifold flange and position the inlet pipe to the exhaust manifold. Loosely install the attaching nuts.
3. Adjust the system. Torque all attaching nuts and bolts to specifications in Part 26-01.
4. Check the system for leaks.

LNT-8000-9000 AND LN-9000—6-71 ENGINE

Removal

1. Loosen the retaining clamps securing the front and rear inlet pipes to the flex connector.
2. Remove the front inlet pipe to manifold clamp. Slide the flex connector rearward and disconnect it from the front inlet pipe. Remove the inlet pipe from the exhaust manifold. Remove the U-bolt and bracket from the inlet pipe.
3. Clean the mounting surface on the exhaust manifold and inlet pipe.

Installation

1. Position the bracket on the inlet pipe. Tighten the U-bolt nuts so that they are snug, but not tight.
2. Position the inlet pipe on the exhaust manifold and loosely install the retaining clamp. Slide the flex connector forward and engage with the inlet pipe.
3. Properly position the inlet pipe, bracket and flex connector, then tighten the clamps and nuts to specifications (Part 26-01).
4. Check the exhaust system for leaks.

W-AND WT-SERIES—6-71 ENGINE

Removal

1. Remove the inlet pipe to engine and inlet pipe to inlet pipe extension clamps.
2. Remove the support bracket clamps on the inlet pipe and inlet pipe extension.
3. Separate and remove the inlet pipe from the inlet pipe extension.
4. Clean inlet pipe mounting flange of the exhaust manifold.

Installation

1. Place the new inlet pipe in position and loosely install the retaining clamps at both ends.
2. Install the support bracket clamps on the inlet pipe and inlet pipe extension.
3. Properly position the inlet pipe and support brackets and tighten all clamps and nuts to specifications (Part 26-01).
4. Check the exhaust system for leaks.

W-AND WT-SERIES—8-71 ENGINE

Removal

1. Remove the inlet pipe(s) to inlet pipe

adapter clamp(s) and inlet pipe(s) to engine clamp(s).
2. Remove the inlet pipe(s).
3. Clean the exhaust manifold flange(s).

Installation

1. Place the new inlet pipe(s) in position and install the exhaust manifold to inlet pipe retaining clamp(s).
2. Position the inlet pipe to inlet pipe adapter clamp.
3. Tighten all clamps to specifications (Part 26-01).
4. Check the exhaust system for leaks.

MUFFLER INLET REAR PIPE AND FLEX CONNECTION

LNT-8000-9000 AND LN-9000—6-71 ENGINE

Removal

1. Loosen the flex connector retaining clamps and slide the flex connector forward.
2. Loosen the rear inlet pipe clamp at the muffler and remove the inlet pipe. Remove the flex connector by sliding it rearward.

Installation

1. Slide the flex connector on the front inlet pipe. Position the rear inlet pipe on the muffler and engage with the flex connector by sliding the connector rearward.
2. Properly position the inlet rear pipe and flex connector and install the three retaining clamps. Tighten the clamps to specifications (Part 26-01).
3. Check the exhaust system for leaks.

INLET PIPE EXTENSIONS

W-AND WT-SERIES

Removal

1. Loosen the inlet pipe extension to muffler clamp.
2. Loosen the inlet pipe to inlet pipe extension clamp and slide it onto the inlet pipe.
3. Remove the inlet pipe extensions from the vehicle.

Installation

1. Extend the flex pipe. Position the flex pipe to the inlet pipe extension and install the clamp.
2. Position the inlet pipe extensions to the inlet pipe and muffler.
3. Position the inlet pipe to inlet pipe extension and inlet pipe extension to muffler clamps.
4. Tighten all clamps to specifications (Part 26-01).

MUFFLER

LN-AND LT-8000 SERIES

Removal

1. Remove the retaining clamp securing the muffler to the outlet pipe and separate the outlet pipe from the muffler.
2. Remove the clamp securing the muffler to the inlet pipe.
3. Loosen the muffler support bracket clamps.
4. Separate the muffler from the inlet pipe and remove it from the vehicle.

Installation

1. Slide the muffler through the retaining clamps and position it on the inlet pipe. Loosely install the retaining clamp.
2. Position the outlet pipe to the muffler and loosely install the retaining clamp.
3. Align the system and torque the attaching nuts and bolts to the specifications in Part 26-01.
4. Check the system for leaks.

LNT-8000-9000 AND LN-9000—6-71 ENGINE

Removal

1. Loosen the muffler inlet and outlet pipe clamps at the muffler flanges. Slide the clamps forward onto the muffler inlet and outlet pipes.
2. Loosen the attaching bolts securing the muffler support brackets to the muffler.
3. Slide the muffler rearward to remove it from the muffler inlet and outlet pipes and the muffler support bracket.

Installation

1. Slide the new muffler through the muffler support brackets and position the muffler inlet and outlet flanges within the inlet and outlet pipe.
2. Tighten the muffler support bracket attaching nuts to specifications (Part 26-01). Properly position the inlet and outlet pipe retaining clamps. Tighten the clamps to specifications.
3. Check the exhaust system for leaks.

W-AND WT-SERIES

Removal

1. Remove the two muffler retaining clamps.
2. Remove the muffler and outlet pipe from the inlet pipe extension.
3. Remove the outlet pipe from the muffler.

Installation

1. Place the outlet pipe on the new muffler.
2. Place the outlet pipe and muffler assembly on the inlet pipe extension and loosely install the two muffler retaining clamps.
3. Tighten the muffler clamps to specification (Part 26-01).
4. Check the exhaust system for leaks.

OUTLET PIPE

LN-AND LT-8000 SERIES

Removal

1. Remove the clamp securing the outlet pipe to the muffler.
2. Remove the outlet pipe.

Installation

1. Position the outlet pipe to the muffler and loosely install the retaining clamp(s).
2. Align the position of the outlet pipe and torque the attaching nuts to the specifications in Part 26-01.
3. Check the system for leaks.

LNT-8000-9000 AND LN-9000—6-71 ENGINE

Removal

1. Loosen the outlet pipe retaining clamp at the muffler. Loosen the flex connector clamps. Remove the outlet pipe support bracket clamps.
2. Disconnect the flex connector from the outlet pipe and remove the outlet pipe from the muffler.

Installation

1. Position the flex connector lower clamp and the muffler clamp on the new outlet pipe.
2. Position the outlet pipe on the muffler outlet flange, and connect the outlet pipe to the flex connector. Loosely install the outlet pipe support bracket clamp.
3. Properly position the outlet pipe, and tighten the flex connector and outlet pipe clamps to specifications (Part 26-01).
4. Check the exhaust system for leaks.

W-AND WT-SERIES

Removal

1. Remove the muffler to outlet pipe clamp.
2. Remove the outlet pipe.

Installation

1. Place a new outlet pipe in position.
2. Install and tighten the muffler to outlet pipe clamp to specifications (Part 26-01).
3. Check the exhaust system for leaks.

OUTLET PIPE FLEX CONNECTOR AND EXTENSION

LNT-8000-9000 AND LN-9000

Removal

1. Loosen the flex connector lower clamp at the outlet pipe and slide the clamp onto the outlet pipe. Remove the outlet pipe extension retaining clamps.
2. Remove the outlet pipe extensions and the connector as a unit and disconnect them.

Installation

1. Install the connector on the outlet pipe extension. Install the outlet pipe extension and flex connector on the outlet pipe. Loosely install the extension pipe clamps, and the flex connector lower clamp in their proper position.
2. Properly position the connector on the outlet pipe and tighten the flex connector lower clamp to specifications (Part 26-01). Position the outlet pipe extension in the flex connector and tighten the lower and upper retaining clamps to specifications.
3. Check the exhaust system for leaks.

COOLING SYSTEM		CORROSION RESISTOR	
Description and Operation	02-01	Removal and Installation	02-03
Draining and Filling	02-02	WATER FILTER AND CONDITIONER	
		Maintenance	02-03

DESCRIPTION AND OPERATION

COOLING SYSTEM

Correct coolant level is essential for maximum circulation and adequate cooling. In addition, for the cooling system to perform its function, it must receive proper care. This includes keeping the radiator fins clean and a periodic inspection of the cooling system for leakage.

Use care when removing the radiator cap to avoid injury from escaping steam or hot water.

Do not remove the radiator cap on vehicles equipped with a coolant recovery system. Add coolant to the plastic bottle only. Maintain level at the specified cold or hot fill mark.

When cooling system is drained, fill radiator with coolant, vent the system by disconnecting heater upper hose and add fluid to specified mark on plastic bottle.

In production, the cooling system is filled with a 45-55 (50-50 for Canada and export) solution of Ford Permanent Anti-freeze and water which prevents corrosion, keeps the cooling system clean, provides anti-freeze protection to -20 (-35 for Canada and export) degrees F in winter and provides for higher summer operation temperatures.

For the most effective cooling system operation, this mixture strength should be maintained all year round and in all climates.

All coolant added should be the specified mixture of Ford permanent anti-freeze and water. If Ford Permanent Anti-freeze is not available, another reputable permanent anti-freeze may be used and diluted with an equal quantity of water.

Ordinary tap water may be used in an emergency except in areas where the water is known to be exceptionally hard or to have a high alkali content. The cooling system should be drained and flushed and the proper mixture of antifreeze added as soon as possible.

To avoid possible overheating in very hot weather, do not use mixtures with more than 50 percent anti-freeze except in areas where anti-freeze protection below -35 degrees F is required. In this case, refer to the coolant mixture chart on the Ford permanent anti-freeze container.

On diesel engines using water only in the cooling system, add a can of Radiator Rust Inhibitor whenever the system is completely refilled.

Do not add any radiator sealers containing water soluble oil to the cooling system as it will make the corrosion resistor inoperative.

A standard ethylene gycol hydrometer can be used to check the

protection level of the long-life coolant.

Do not backflush cooling systems that have a water shut-off valve in the heater system, or damage to the valve can result.

To prevent damage to the cooling system during periods of below freezing ambient temperature, when water or anti-freeze is added to the supply tank, always operate the engine at fast idle for 30 minutes before letting the truck stand with the engine off for prolonged periods. This will allow a uniform mixture throughout the cooling system and prevent damage by freezing, when sufficient anti-freeze is used.

If the fan drive belt(s) are noisy, check the tension of the belt(s) to make certain it is within specifications. Also, check for misaligned pulleys. If the drive belt(s) are worn or frayed, replace, following the procedure in Part 27-04.

DRAINING AND FILLING THE COOLING SYSTEM

100-900 SERIES TRUCKS

To prevent loss of anti-freeze when draining the radiator, attach a hose on the radiator drain cock and drain the coolant from the radiator into a clean container.

To drain the radiator, open the drain cock located at the bottom of the radiator and remove the radiator or supply tank cap. The cylinder block of the V-8 engine is drained by removing the drain plugs located on both sides of the block. The 6-cylinder engines have one drain plug located at the left rear of the cylinder block.

To fill the cooling system, install the cylinder block drain plug(s) and close the radiator drain cock. On 100-750 Series trucks, disconnect the heater outlet hose at the water pump to bleed or release trapped air in the system. When the coolant begins to escape, connect the heater outlet hose.

On C-800-900 Series trucks with super duty engines, open the air vent valve located at the front of the intake manifold to bleed the system. When coolant begins to escape at the opening, close the valve finger-tight. Do not overtighten, as the air vent valve is designed to be closed finger-tight only.

C-Series trucks equipped with Ford Diesels have an auxiliary air bleed connecting the supply tank to the top of the radiator tank. L-Series trucks have an automatic air bleed.

On downflow radiators, operate the engine and add more coolant, if necessary, to fill the radiator to the proper level. On trucks without a supply tank, fill the radiator one inch above the baffles (or core). On trucks equipped with a supply tank, fill the supply tank 2/3 full.

On L-Series gasoline and Ford V-8 Diesel engines, with crossflow radiators, fill until the coolant is 1 inch from the top of the tank with engine cold. **(Caution—Do not operate engine if coolant level is below sightglass.)** (Refer to Fig. 1).

On L-Series—Cummins and Detroit Diesel engines, fill until the coolant is visible through the upper sightglass with engine cold. **(Caution—Do not operate engine if coolant level is below the lower sightglass.)** (Refer to Fig. 2).

After the initial fill, the coolant level will drop approximately 1 quart after the engine has been operated about 20 minutes at 2000 rpm. This is due to the displacement of entrapped air. Refill radiator as required.

CUMMINS NH-SERIES ENGINE

To prevent loss of anti-freeze when draining the radiator, attach a hose to the radiator drain cock and drain the coolant from the radiator into a clean container.

To drain the radiator, open the drain cock located at the bottom of the radiator. The cylinder block is drained by opening one drain plug located at the right rear of the block. Also, drain the oil cooler and heat exchanger (if so equipped).

To fill the cooling system, close the drain cocks, venting is automatic.

Operate the engine and add more coolant, if necessary, to fill the radiator to the proper level. On trucks without a supply tank, fill the radiator one inch above the baffle on downflow radiators. On crossflow radiators, fill to the sight glass. On trucks equipped with a supply tank, fill the supply tank 2/3 full. After the initial fill, the coolant level will drop approximately 1 quart when the engine has been operated about 20 minutes at 2000 rpm. This is due to the displacement of entrapped air.

DETROIT DIESEL ENGINES

To drain the radiator, open the drain petcock at the bottom of the radiator and drain the coolant into a container to prevent loss of anti-freeze. The radiator will drain faster if the filler cap is removed.

To drain the cylinder block, open the two drain petcocks on each side of the engine block and on the bottom of the oil cooler.

To fill the cooling system, close the drain petcocks and pour the coolant into the radiator. Operate the engine until operating temperature is obtained and check the coolant level.

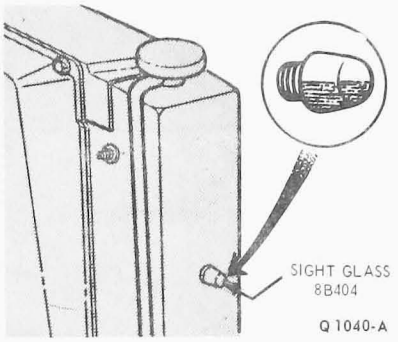

FIG. 1 Sightglass—L-Series—Gasoline and Ford V-8 Diesel Engines with Crossflow Radiator

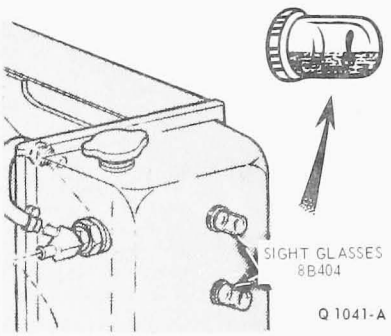

FIG. 2 Sightglass—L-Series—Cummins and Detroit Diesel Engines

FORD V-8 DIESEL ENGINES

To drain the radiator, open the drain petcock at the bottom of the radiator and drain the coolant into a container to prevent loss of anti-freeze. The radiator will drain faster if the filler cap is removed.

To drain the cylinder block, open the drain cocks at the thermostat housing and oil cooler, and remove the drain plugs from the rear of the cylinder block (one on each side).

To fill the cooling system, install the cylinder block plugs and close the drain cocks at the radiator, thermostat housing and oil cooler. Pour the coolant into the radiator. Operate the engine until operating temperature is reached and check the coolant level.

CORROSION RESISTOR

CUMMINS DIESEL ENGINES

Removal and Installation

Check the coolant chromate concentration as described under Check Engine Coolant in the Cummins Engine Operation and Maintenance Manual.

To change the filter element:

1. Close the shut-off valves on the inlet and drain lines of the Filter assembly. Unscrew the drain plug at the bottom of the housing (Fig. 3).
2. Remove the cover retaining bolts. Remove the cover (with hose attached) and gasket. Discard the gasket. Remove the upper plate, element, lower plate and the spring from the housing. Discard the element.
3. Polish the surface of the lower plate. If less than one-half of the upper and lower surfaces of the plate can be exposed by polishing, replace the plate.
4. Install the spring and lower plate. Remove the transparent bag from the new resistor element, and install the element in the housing.
5. Install the upper plate, gasket and cover. Install the drain plug, and open the shut-off valves in the corrosion resistor inlet and drain lines. **Do not add any radiator sealers containing water soluble oil to the cooling system as it will make the corrosion resistor and lower plate inoperative.**

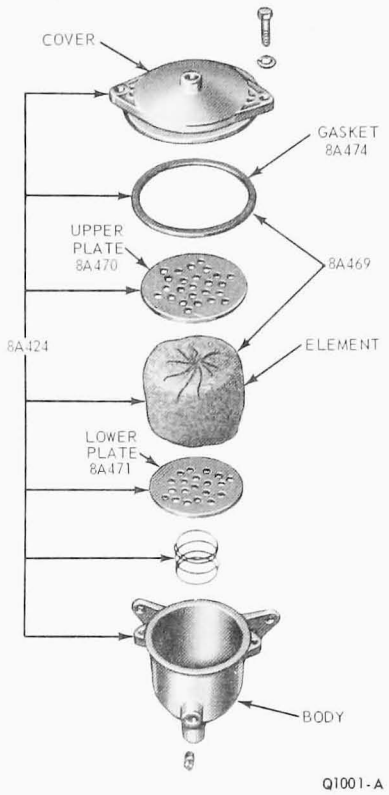

FIG. 3 Corrosion Resistor

WATER FILTER AND CONDITIONER

DETROIT DIESEL ENGINES

For maintenance of the engine coolant and water filter, refer to the Detroit Diesel Engine Maintenance Manual.

DESCRIPTION AND OPERATION

RADIATOR

All radiators except 8-cylinder Bronco and L-Series trucks are of the tube and corrugatedfin-core type with the tubes arranged for vertical flow of the coolant. Two header tanks, one on the top and one on the bottom of the radiator provide uniform distribution of the coolant to the tubes. The radiator outlet port (lower header tank) is connected to the water pump inlet port. The radiator inlet port(s) (upper header tank) is connected to the coolant outlet elbow of the engine, thereby permitting coolant circulation through the radiator when the thermostat is open.

The Bronco V-8 and L-Series radiator is of the cross-flow type, with the tubes and fins arranged for horizontal flow. The header tanks are therefore located at the sides of the radiator.

An expansion tank is provided as a means of filling and checking the system.

SUPPLY TANK

C-Series trucks and 8-cylinder Bronco have a separate coolant supply or expansion tank, with the radiator cap on this tank.

On all other trucks the radiator upper header tank serves as the supply and expansion tank.

COOLANT RECOVERY SYSTEM

Some F-100, F-250 6-cylinder models and Bronco units with 8-cylinder engines are equipped with a coolant recovery system. Do not remove the radiator cap on these vehicles— add coolant to the plastic bottle only. Maintain level at the specified cold or hot fill mark.

When cooling system is drained, fill radiator with coolant according to the instructions in Part 27-02.

TESTING

PRESSURE TEST

It is recommended that a cooling system pressure test gauge be used to properly test the system for:

1. Blown or leaking cooling system sealing gaskets.
2. Internal or external cooling leakage.
3. Pressure cap malfunction.

Some modification of existing pressure testers may be required in order to use this procedure.

1. Shut the engine off. **To prevent loss of coolant and to avoid the danger of being burned, place a cloth over the cap and rotate the cap slowly counterclockwise to first stop and allow pressure to escape completely. Then turn cap again slowly counterclockwise to remove.**
2. After the cooling system pressure has been released, remove the radiator cap, wet the rubber sealing surface and reinstall cap tightly on the radiator.
3. Disconnect the electrical connector from the engine temperature sending unit and remove the temperature sending unit from the manifold.

With the radiator cap installed, only a small amount of coolant will be lost when the sending unit is removed.

4. Install an adaptor fitting (3/8 N.P.T. male thread on one end, and a hose connection on the other end to accommodate the tester hose) tightly into the intake manifold or cylinder head in place of the sending unit.
5. Remove the radiator overflow hose from the retainer clips. Make sure the hose is firmly installed on the radiator overflow tube and is in good condition. Insert the free end of the overflow hose into a container of water.
6. Attach the pressure pump and gauge to the adapter fitting and pressurize the cooling system until bubbles are observed in the water container. Discontinue pumping when bubbles appear.

When the bubbles cease, read the pressure gauge. The gauge reading is the pressure relief of the cap and should be within specifications. If the pressure reading exceeds the specified limit, replace the radiator cap.

7. If bubbles continue and the pressure drops below 10 psi, the radiator cap is not holding pressure. Release pressure and wash cap in clean water to dislodge any foreign matter from the valves. Check the rubber sealing surface of the cap and also the cap sealing surface in the radiator neck. Inspect the cam lock flanges on both sides of the filler neck for maximum cap engagement.
8. Recheck the cooling system as outlined in step 6. If the cap still does not hold pressure, the cap is damaged and must be replaced. Recheck system after a new cap is installed to assure that the system will now hold pressure.
9. If the bubbles in the water container cease and the radiator cap is within pressure specifications, observe gauge reading for approximately two minutes. Pressure should not drop during this time.
10. If pressure drops, check for leaks at the engine to heater core hoses, engine to radiator hoses, by-pass hose, water valve hose (A/C equipped), thermostat housing gasket, etc. Any leaks which are found must be corrected and the system rechecked.
11. If the system holds pressure, remove the radiator cap to release the pressure, then reinstall the cap.
12. Remove the adapter from the manifold or cylinder head and reinstall the temperature sending unit. Check coolant level and replenish if necessary with the correct coolant solution.

THERMOSTAT TEST

TRUCKS EQUIPPED WITH GASOLINE ENGINES

It is good practice to test new thermostats before installing them in the engine.

Remove the thermostat and immerse it in boiling water. Replace the thermostat if it does not open more than 1/4 inch.

If the problem being investigated is insufficient heat, the thermostat should be checked for leakage. This may be

done by holding the thermostat up to a lighted background. Light leakage around the thermostat valve (thermostat at room temperature) is unacceptable and the thermostat should be replaced. It is possible, on some thermostats, that a slight leakage of light at one or two locations on the perimeter of the valve may be detected. This should be considered normal.

TRUCKS EQUIPPED WITH CUMMINS DIESEL ENGINES

Suspend a thermometer and the thermostat to be tested in a container of water so that neither one touches the container. Heat the water container until the thermostat begins to open and note the temperature. Continue heating the water until the thermostat is fully open. The temperature stamped on the thermostat is that at which the thermostat should begin to open. The fully open temperatures for the thermostats are listed in Specifications.

TRUCKS EQUIPPED WITH DETROIT DIESEL ENGINES

Refer to the Detroit Diesel Maintenance Manuals for the test procedures.

TRUCKS EQUIPPED WITH FORD V-8 DIESEL ENGINES

Refer to the appropriate Caterpillar Diesel engine service manual.

CORROSION RESISTOR TEST

CUMMINS DIESEL ENGINES

Check the coolant chromate concentration to determine if the corrosion resistor element should be changed.

WATER FILTER AND CONDITIONER

DETROIT DIESEL ENGINES

For coolant system checks, refer to the Detroit Diesel Engine Maintenance Manual.

ADJUSTMENTS

BELT TENSION—GASOLINE ENGINES

100-350 SERIES TRUCKS

1. Install the belt tension tool on the drive belt(s) (Fig. 1) and check the tension following the instructions of the tool manufacturer.
2. If adjustment is necessary, loosen the alternator mounting bolts and move the alternator adjusting arm bolt. Move the alternator toward or away from the engine until the correct tension is obtained (Specifications). Remove the gauge. Tighten the alternator adjusting arm bolt and the mounting bolts. Install the tension gauge and check the belt tension.

500-900 SERIES TRUCKS

1. Install the belt tension tool on the drive belt(s) (Fig. 1) and check the tension following the instructions of the tool manufacturer.

The tension is checked between the water pump pulley and the alternator pulley on single or double fan drive belts and all alternator and water pump fan drive belts. The tension on separate fan drive belts is checked between the fan pulley and the crankshaft pulley. The tension of the air compressor drive belt is checked between the compressor pulley and the fan pulley or the crankshaft (C-Series). The belt tensions are given in Specifications.

2. If adjustment is necessary, follow the applicable procedure.

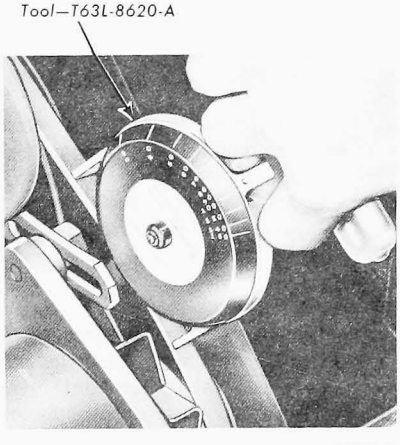

FIG. 1 Checking Drive Belt Tension

BELT TENSION—DIESEL ENGINES

FORD V-8 DIESEL ENGINES

To check belt tension, exert 25 lb. force on the belt midway between the pulleys. Correctly adjusted belts will deflect 1/2 to 3/4 inch.

Single or Double Fan Belts

Loosen the alternator mounting bolts and the alternator adjusting bracket bolt. Move the alternator generator toward or away from the engine until the correct belt tension (Specifications) is obtained. Tighten the alternator mounting bolts and the adjusting bracket bolt before checking the tension.

Separate Fan Belt

Loosen the fan bracket mounting bolts. Slide the bracket up or down until the correct belt tension (Specifications) is obtained. Tighten the bracket bolts before checking the tension.

On a truck equipped with an air compressor, it may be necessary to loosen the compressor drive belt in order to obtain proper fan drive belt adjustment. Adjust the compressor drive belt after the fan drive belt adjustment is complete.

Air Compressor Belt

Loosen the air compressor mounting bolts and slide the compressor in its bracket until the correct tension (Specifications) is obtained. Tighten the compressor mounting bolts before checking the deflection. **Adjust the air compressor drive belt whenever the fan drive belt is adjusted or replaced. Adjust the air compressor drive belt last.**

CUMMINS NH-SERIES DIESEL ENGINES FAN BELTS

Loosen the adjusting screw locknut on the fan hub. Adjust the fan hub adjusting screw to obtain the specified fan belt tension (Specifications) and tighten the locknut.

Water Pump Belts

1. Loosen the alternator adjusting bracket and the alternator to mounting bracket bolts. Loosen the water pump retainer mounting bolts.
2. Pivot the water pump assembly to obtain the specified drive belt tension (Specifications) and tighten

the water pump retainer bolts to specifications.
3. Adjust the alternator to obtain the specified drive belt tension (Specifications) and tighten the adjusting bracket bolt and alternator to mounting bracket bolts.

DETROIT DIESEL ENGINES

If the belt needs adjustment, loosen the support bracket mounting bolts and the adjusting bolt. Move the bracket up or down, as required, to obtain the specified belt tension (Specifications) and tighten the adjusting bolt. Check the belt tension again. When the belt is properly adjusted, tighten the bracket mounting bolts.

REMOVAL AND INSTALLATION

FAN

ALL EXCEPT ECONOLINE WITH 6-CYLINDER ENGINES

Removal and Installation
1. Examine the fan mounting system to determine whether or not the drive belt tension should be relieved. Loosen fan drive belt(s) tension, if necessary.
2. Remove the fan blade retaining bolts and remove the fan and spacer (if so equipped).
3. Position the spacer (if so equipped) and fan blade on the water pump hub or the crankshaft damper (low-mount fan). Tighten the retaining bolts.
4. Adjust fan belt(s) tension.

ECONOLINE WITH 240 6-CYLINDER ENGINE

Removal and Installation

The radiator must be removed in order to remove the fan. Refer to the instructions in this Section for procedures.
1. With the radiator removed, release the fan belt tension and remove the bolts retaining the fan and spacer to the water pump pulley and remove the fan, spacer and retaining bolts.
2. Position the fan, spacer and bolts to the water pump pulley and install the retaining bolts, torquing to the proper value.
3. Adjust fan belt tension to specifications.
4. Install the radiator per instructions.

FAN BELT

ALL GASOLINE ENGINES

Removal and Installation
1. Loosen the alternator mounting bolts and the alternator adjusting arm bolt. Move the alternator toward the engine. Remove the belt from the alternator, crankshaft pulley, and water pump pulley. Lift the belt(s) over the fan.
2. Place the belt(s) over the fan. Insert the belt(s) in the water pump pulley, crankshaft pulley, and alternator pulley grooves. Adjust the belt tension to specifications.

CUMMINS NH DIESEL ENGINES

Removal and Installation
1. Loosen the cooling fan hub locknut and back-off the adjusting screw.
2. Remove the drive belts from the compressor pulley and the fan hub.
3. Position the new drive belts on the cooling fan hub and the compressor pulley. Adjust the tension of the drive belts to specifications, and tighten the fan hub locknut.

DETROIT DIESEL ENGINES

Removal and Installation
1. Loosen the adjusting bolt on the top of the fan pulley support bracket.
2. Loosen the adjusting bracket assembly bolts and let the bracket slide down.
3. Slip the belts off the pulleys and over the fan.
4. Position the new belts on the pulleys and adjust the belts by following the procedure under Belt Tension—Detroit Diesel Engines in this section of the book.

DRIVE BELTS

CUMMINS NH DIESEL ENGINES

Removal and Installation
1. Remove the cooling fan drive belts and the power steering pump drive belts from the compressor pulley.
2. Loosen the water pump retaining ring mounting bolts. Loosen the alternator to mounting bracket bolts and the adjusting bracket bolt.
3. Rotate the water pump and remove the drive belt from the compressor pulley and the water pump pulley.
4. Position a new water pump drive belt on the compressor pulley and the water pump pulley. Rotate the water pump to obtain the specified drive belt tension, Specifications, and tighten the retaining ring bolts.
5. Adjust the alternator to obtain the specified belt tension, Specifications, and tighten the adjusting bracket and alternator mounting bolts.
6. Install the power steering pump drive belts and adjust the belt tension to specifications. Install the cooling fan drive belts and adjust the belt tension to specification.

FORD V-8 DIESEL ENGINES—C-SERIES

Removal and Installation

The fan on the C-Series truck is mounted on the crankshaft. A belt from the fan pulley drives the air compressor. The next pulley rearward on the crankshaft drives the power steering pump. A double-grooved pulley at the rear drives the water pump and alternator by means of two belts.

To replace the water pump alternator belts, first loosen the air compressor drive belt idler pulley and remove the air compressor drive belt.

Next, loosen the power steering pump mounting, move the pump inward and remove the power steering pump drive belt.

Loosen the alternator mounting and adjusting bolts, move the alternator

inward and remove the drive belts.

Belts mounted in pairs must be replaced in pairs.

Install the new alternator-water pump belts on the pulleys. Adjust the belts to the specified tension and tighten the alternator mounting and adjusting bolts.

Position the power steering pump drive belt on the pulleys and adjust the belt tension, Specifications. Tighten the power steering pump mounting bolts.

Position the air compressor drive belt on the drive and idler pulleys. Adjust the idler pulley until the drive belt has the specified tension, Specifications. Tighten the idler pulley adjusting bolt.

FORD V-8 DIESEL ENGINES—F-B-SERIES

Removal and Installation

A four-groove pulley is used on the crankshaft. The two grooves nearest the engine are used for the fan, water pump and alternator drive belts. The next groove forward is used for the air compressor drive belt. If a power steering pump is used, it is belt driven from the front pulley groove.

To replace the fan, water pump and alternator belts, first loosen the power steering pump bracket (if so equipped), move the pump inward and remove the power steering pump drive belt. Next loosen the air compressor drive belt idler pulley and remove the air compressor drive belt. Loosen the alternator mounting bolt and the adjusting bolt and remove the two fan belts. **Always replace double belts in pairs.**

Position the fan belts on the pulleys and adjust the tension, Specifications, of the belts by moving the alternator outward. Tighten the alternator mounting and adjusting bolts.

Position the air compressor drive belt on the pulleys and adjust the idler pulley until the drive belt has the specified belt tension, Specifications.

Position the power steering pump drive belt (if so equipped) on the pulleys and move the power steering pump outward until the belt has the specified belt tension, Specifications.

RADIATOR HOSE

Removal and Installation

The cooling system hoses should be replaced whenever they become cracked or deteriorated, or have a tendency to collapse.

Partially drain the cooling system to replace a cooling system upper hose(s). Drain the cooling system to replace the radiator outlet hose.

1. Drain or partially drain the radiator, then loosen the clamps on each end of the hose(s) to be removed. Slide the hose(s) off the connections.
2. Position the clamps on each end of the new hose. Slide the hose onto the connections, then tighten the clamps. **If the connections have a bead around the edges, make sure the clamps are located beyond the beads.**
3. Fill the cooling system with coolant and bleed the system.
4. Operate the engine for several minutes, then check the hose(s) and connections for leaks.

THERMOSTAT REPLACEMENT

Whenever changing the thermostat to a higher or lower temperature range on trucks equipped with automatic shutters, change the shutterstat accordingly to a higher or lower range.

A poppet-type thermostat is used with all engines.

When the thermostat is closed, coolant flows to the water pump through a by-pass passage at the front of the engine. When the thermostat is open, coolant flows through the coolant outlet elbow (thermostat housing) to the radiator.

Super Duty V-8 engines are equipped with a front and a rear thermostat. The front thermostat is mounted inside the water outlet elbow. The rear thermostat is mounted inside the intake manifold at the rear.

The thermostat used in production is a high temperature thermostat for use with a 45-55 mixture of water and permanent-type anti-freeze. A low temperature thermostat should be installed if a non-permanent type anti-freeze and water coolant solution is used (except on trucks with automatic radiator shutters).

Do not attempt to repair the thermostat. It should be replaced if it is not operating properly.

Check the thermostat before installing it, following the procedure under Thermostat Test, Testing.

6-CYLINDER ENGINES—GASOLINE

Replacement of the thermostat in 6-cylinder Econoline vehicles requires removal and installation of the radiator. Refer to the radiator part of this section for instructions on removal and installation. Otherwise, the instructions given below also apply to the 6-cylinder Econoline thermostat installation.

Removal

1. Drain the radiator so that the coolant level is below the thermostat.

On C-Series trucks remove the supply tank hose at the coolant outlet elbow.

2. Remove the coolant outlet elbow retaining bolts. Pull the elbow away from the cylinder head sufficiently to provide access to the thermostat. Remove the thermostat and gasket.

Installation

1. Clean the coolant outlet elbow and cylinder head gasket surfaces. Coat a new gasket with water-resistant sealer. Position the gasket on the cylinder head opening. The gasket must be positioned on the cylinder head before the thermostat is installed.
2. The coolant outlet elbow contains a locking recess into which the thermostat is turned and locked. Install the thermostat with the bridge section in the outlet elbow. Turn the thermostat clockwise to lock it in position on the flats cast into the outlet elbow.
3. Position the coolant outlet elbow against the cylinder head. Install and torque the retaining bolts to specifications.

On C-Series trucks connect the supply tank hose.

4. Fill and bleed the cooling system. Check for leaks and proper coolant level after the engine has reached normal operating temperatures.

V-8 ENGINES—GASOLINE

On 8-cylinder Econoline vehicles, the engine cover and air cleaner must be removed for access to the thermostat. Otherwise, instructions given below also apply to thermostat replacement on this vehicle.

Removal

1. Drain the radiator so that the coolant level is below the thermostat.

On C-Series trucks remove the supply tank hose at the water outlet housing.

2. Disconnect the by-pass hoses at the water pump and intake manifold. Remove the by-pass tube. Remove the water outlet housing retaining bolts. Bend the radiator upper hose upward and remove the thermostat and gasket.

Installation

1. Clean the water outlet housing gasket surfaces. Coat a new water outlet housing gasket with water-resistant sealer. Position the water outlet housing gasket on the intake manifold opening.

2. Install the thermostat in the intake manifold opening with the copper pellet or element toward the engine and the thermostat flange positioned in the recess. If the thermostat is improperly installed, it will cause a retarded flow of coolant.
3. Position the water outlet housing against the intake manifold. Install and torque the retaining bolts to specifications. Install the water by-pass line and tighten hose connections.

On C-Series trucks connect the supply tank hose.

4. Fill and bleed the cooling system. Operate the engine until normal operating temperature is reached; then check the coolant level and check for leaks.

CUMMINS NH-SERIES DIESEL ENGINES—L-, LN-, LT-, LNT-AND W-SERIES TRUCKS

Removal

1. Drain the cooling system to below the thermostat level.
2. Disconnect the oil cooler coolant hose, radiator supply tank vent line, and air compressor coolant line from the thermostat housing.
3. Close the air control valve and disconnect the air hoses from the shutterstat, if so equipped.
4. Remove the thermostat housing retaining bolts. Move the thermostat housing forward and to one side, then remove the thermostat. Discard the gasket.

Installation

1. Clean and apply water-resistant sealer to the gasket surfaces at the coolant manifold and thermostat housing.
2. Position the thermostat in the housing with the V notch at the top to vent as much air as possible. **If the thermostat is not properly installed, an air lock and incomplete coolant circulation may result.**
3. Install a new gasket on the thermostat housing and position the housing to the water manifold. Install and tighten the retaining bolts.
4. Connect the oil cooler coolant hose, radiator supply tank vent line, and air compressor water line to the thermostat housing. Connect the air hoses to the shutterstat and open the air control valve.
5. Fill the cooling system. Operate the engine and check for coolant leaks.

DETROIT DIESEL ENGINES

For thermostat replacement procedures, refer to the appropriate Detroit Diesel Highway Maintenance Manual.

FORD V-8 DIESEL ENGINES

For thermostat replacement procedures, refer to the appropriate Caterpillar Service Manual.

RADIATOR

Radiator shroud note: Fiberglass shrouds are retained to the radiator support with bolts having a flat washer between the bolt head and the fiberglass. Always assemble in this manner.

ECONOLINE

Removal

1. Refer to Fig. 2.
2. Drain the cooling system.
3. Open the hood and raise the support rod to hold the hood open.
4. Disconnect the upper radiator hose at the radiator.
5. Disconnect the lower radiator hose at the radiator.
6. Disconnect the transmission oil cooler lines from the radiator (if so equipped).
7. On a 240-6 only, remove the right hood lock bracket and bolts from the radiator grille.
8. Remove the 4 bolts retaining the

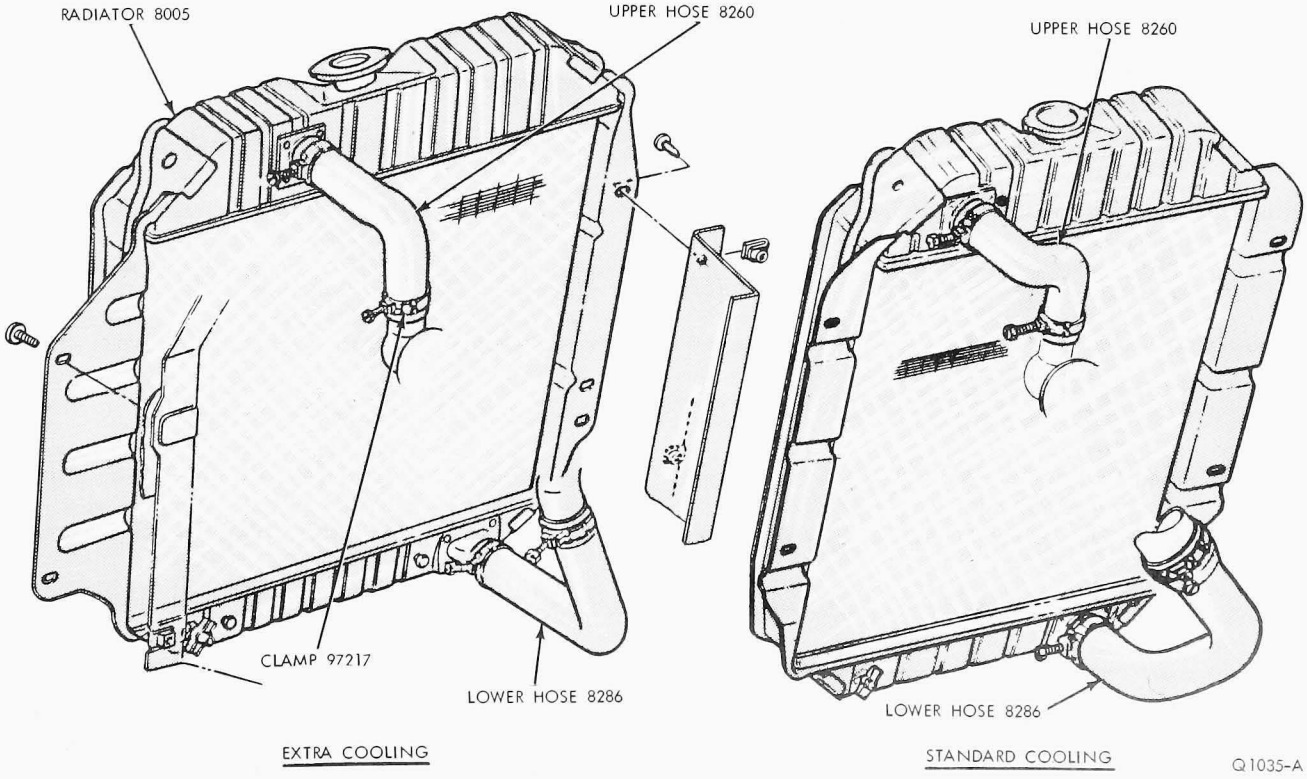

FIG. 2 Radiator and Related Parts—Econoline— Typical

radiator to the radiator support and remove the radiator.

Installation

1. If a new radiator is to be installed, remove the drain cock from the old radiator and install it in the new radiator. On a vehicle with automatic transmission, remove the oil cooler line fittings from the old radiator and install them in the new radiator, using oilresistant sealer M-46-11.

On a vehicle with a coolant recovery system, remove the reservoir from the old radiator and install it on the new radiator.

2. Position the radiator assembly and install the support bolts.
3. Connect the radiator upper and lower hoses.

On a vehicle with automatic transmission connect the oil cooler lines.

4. Install the hood lock bracket and bolts.
5. Close the drain cock. Fill and bleed the cooling system.
6. On 6-cylinder engines equipped with a coolant recovery system completely fill the radiator through the filler cap opening of the radiator upper tank. The cap may be removed by turning to the stop and, pressing down on the cap, force the cap past the **stop** tangs on the filler neck. Engine should be running at idle speed to circulate the coolant and eliminate any trapped air in the system. Install the radiator cap. Fill the coolant reservoir with one quart of coolant. Operate vehicle until normal engine temperature is evident. Check coolant reservoir to see if coolant level is noted at the **Engine Hot** level. If necessary, add coolant to bring to this level.
7. Operate the engine and check for leaks at the hose connections and the automatic transmission oil cooler lines. Check the automatic transmission fluid level.

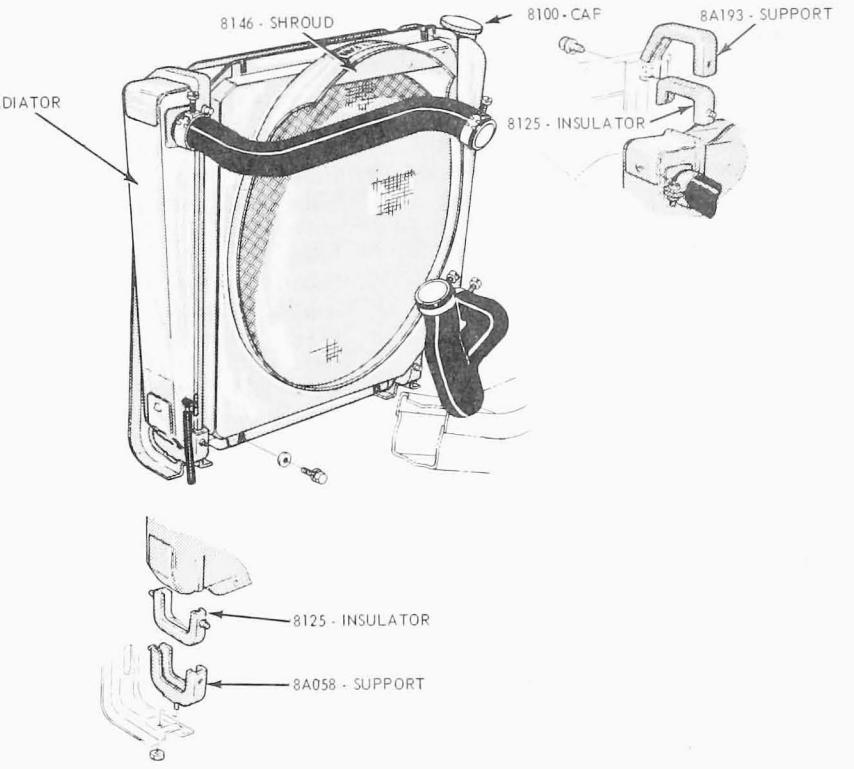

FIG. 3 Radiator and Related Parts—Bronco—Typical

BRONCO (WITH 200 6-CYLINDER ENGINE)

Removal

Refer to Figure 3.

1. Drain the cooling system.
2. Disconnect the upper hose at the radiator.
3. Disconnect the lower hose at the radiator.
4. Remove the radiator retaining screws, and remove the radiator.

Installation

If a new radiator is to be installed, remove the drain cock from the old radiator and, using water-resistant sealer, install it on the new radiator.

1. Position the radiator, and install the retaining screws.
2. Connect the lower hose at the radiator.
3. Connect the upper hose at the radiator.
4. Fill and bleed the cooling system.
5. Operate the engine and check for leaks.

BRONCO (WITH 302 8-CYLINDER ENGINE)

Removal

Refer to Figure 3.

1. Drain the cooling system.
2. Disconnect the transmission cooler lines if so equipped.
3. Disconnect the upper hose at the radiator.
4. Loosen the two shroud lower retaining bolts.
5. Remove the two shroud upper retaining bolts.
6. Position the radiator shroud over the fan, clear of the radiator.
7. Disconnect the lower hose at the radiator.
8. Remove the two radiator upper supports (1 bolt each, Fig. 6) and remove the radiator.

Installation

If a new radiator is to be installed, remove the drain cock from the old radiator and, using water-resistant sealer, install it in the new radiator.

1. Slide the radiator into the lower supports (Fig. 6) and install the upper supports.
2. Connect the lower hose to the radiator.
3. Position the shroud to the radiator and install the retaining bolts.
4. Connect the upper hose to the radiator.
5. Connect the transmission cooler lines if so equipped.
6. Fill the cooling system, bleeding air as necessary.
7. Operate the engine and check for leaks.

P-SERIES (WITH 240, 300 6-CYLINDER ENGINES)

Removal

The 6-cylinder P-Series radiator installations are shown in Fig. 4.

1. Remove the hood. Disconnect the headlights and parking lights at the bullet connectors. Remove the grille, headlights, parking lights, wind deflector and hood lower weatherstrip as an assembly. Drain the cooling system.
2. If equipped with a fan shroud, remove the fan, spacer, water pump pulley and drive belt.

Disconnect the radiator upper hose

at the radiator and the thermostat housing.

3. Disconnect the radiator lower hose at the water pump.

If equipped with an automatic transmission, disconnect the transmission oil cooler line at the radiator lower hose tee.

Remove the radiator retaining bolts and radiator support tie-bar; then remove the radiator and shroud (if so equipped).

Installation

1. If a new radiator is to be installed, transfer the hoses, draincock and fan shroud (if so equipped) to the new radiator. **Apply water-resistant sealer to the threads of the drain cock.**
2. Position the radiator in the chassis and install the retaining bolts and radiator support tie-bar. Connect the radiator upper hose. Connect the transmission oil cooler coolant line (if so equipped) to the radiator lower hose tee. Connect the radiator lower hose.

If equipped with a fan shroud, install the fan, spacer and drive belt. Adjust the belt tension to specifications.

3. Fill and bleed the cooling system. Operate the engine until it reaches normal operating temperature and check the coolant level. Check for leaks.
4. Install the grille, headlights, parking lights, wind deflector and hood lower weatherstrip. Install the hood and retaining bolts; then adjust the hood at the hinge retaining bolts.

F-100-350 SERIES (WITH 240-300 6-CYLINDER ENGINES)

Removal

The F-100-350 radiator installations are shown in Figure 5.

1. Drain the cooling system. Disconnect the radiator upper hose at the coolant outlet elbow and the radiator lower hose at the water pump.

On a truck with an automatic transmission, disconnect the transmission oil cooler coolant line at the radiator.

2. If equipped with a fan shroud, loosen the generator or alternator adjusting arm bolts and loosen the fan belt. Remove the cooling fan retaining bolts, and remove the fan, spacer, water pump pulley and fan belt.
3. Remove the radiator retaining bolts, and remove the radiator and fan shroud (if so equipped).

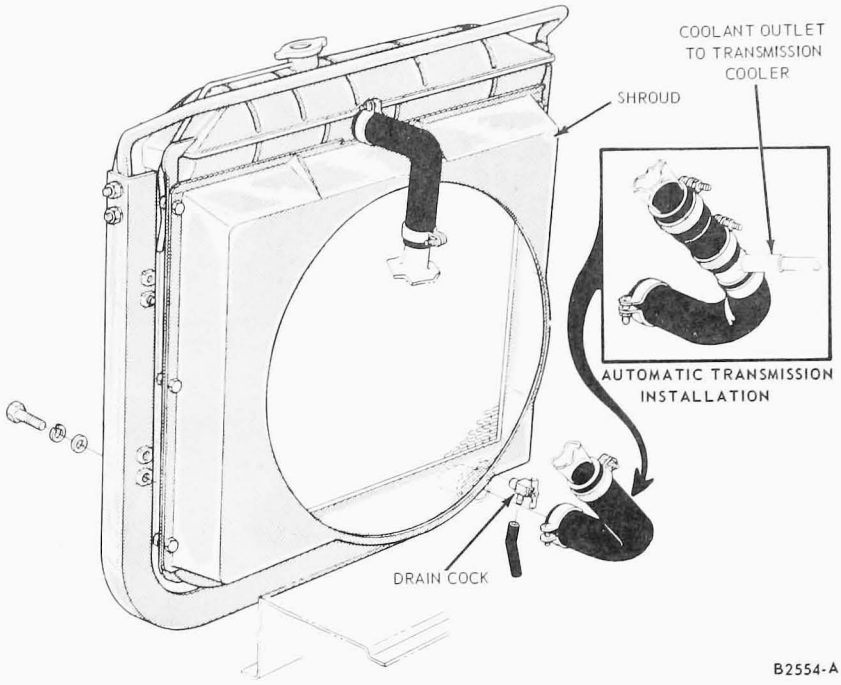

FIG. 4 Radiator and Related Parts—P-Series—Typical

Installation

1. If a new radiator is to be installed, transfer the hoses, draincock, fan shroud, and coolant recovery reservoir (if so equipped) to the new radiator. **Apply water-resistant sealer to the thread of the draincock.**
2. Position the radiator (and shroud) in the chassis and install the retaining bolts. Connect the radiator hoses to the coolant outlet elbow and water pump.

If equipped with an automatic transmission, connect the oil cooler coolant-line to the radiator lower tank.

3. If equipped with a fan shroud, install the water pump pulley, spacer, cooling fan and fan belt. Adjust the drive belt tension to specifications.
4. Fill and bleed the cooling system.

On 6-cylinder engines equipped with a coolant recovery system (Fig. 4), fill the radiator, through the filler cap opening of the radiator upper tank, completely full. The cap may be removed by turning to the stop and, pressing down on the cap, force the cap past the **stop** tangs on the filler neck. Engine should be running at idle speed to circulate the coolant and eliminate any trapped air in the system. Install the radiator cap. Fill coolant reservoir with one quart of coolant. Operate vehicle until normal engine temperature is evident. Check coolant reservoir to see if coolant level is noted at the **Engine Hot** level. If necessary, add coolant to bring to this level. Operate the engine until it reaches normal operating temperature; check the coolant level and the system for leaks.

B-F-500-600 SERIES (WITH 240, 300 6-CYLINDER ENGINES)

Removal

The B-and F-Series radiator installation is shown in Figure 6.

1. Drain the cooling system. Disconnect the radiator upper hose at the coolant outlet elbow and the radiator lower hose at the water pump.
2. Loosen the generator or alternator adjusting arm bolts and loosen the fan belt. Remove the cooling fan retaining bolts, and remove the fan, spacer, water pump pulley and fan belt.
3. Remove the radiator retaining bolts, and remove the radiator and fan shroud.

Installation

1. If a new radiator is to be installed, transfer the hoses, drain cock and fan shroud to the new radiator. **Apply water-resistant sealer to the threads of the draincock.**
2. Position the radiator and shroud in the chassis and install the retaining bolts. Connect the radiator hoses to the coolant outlet elbow and water pump.
3. Install the water pump pulley, spacer, cooling fan and fan belt. Adjust the drive belt tension to specifications.

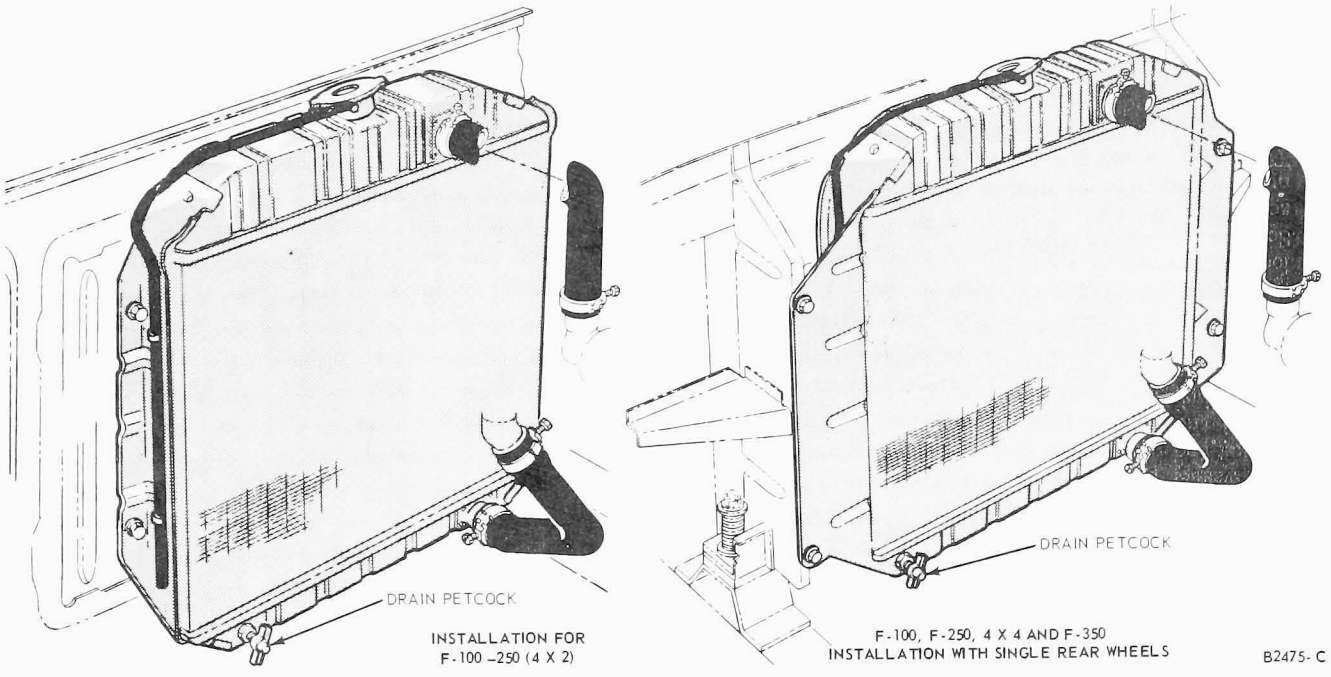

FIG. 5 Radiator Installation—F-100-350 Series—Typical

4. Fill and bleed the cooling system. Operate the engine until it reaches normal operating temperature; check the coolant level and check the system for leaks.

C-500-600 SERIES (WITH 240, 300 6-CYLINDER ENGINES)

Removal

The C-500-600 radiator installation is shown in Figure 7.

1. Drain the cooling system. Disconnect the upper radiator hose from the radiator. Remove the bolt securing the radiator lower hose tube extension to the frame. Disconnect the tube extension from the lower radiator hose.
2. Disconnect the radiator vent line at the radiator. Remove the cooling fan retaining bolts and remove the fan assembly. Remove the bolts securing the radiator brace to the frame.
3. Remove the radiator retaining bolts and remove the radiator, fan shroud and hose as an assembly.

Installation

1. If a new radiator is to be installed, transfer the radiator lower hose, draincock, fan shroud, struts, and vent line fittings to the new radiator. **Apply water-resistant sealer to the threads of the draincock.** Position the radiator assembly in the chassis and install the retaining bolts. Position the struts to the frame and install the retaining bolts.
2. Install the cooling fan assembly and adjust the belt tension to specifications. Connect the radiator vent line to the radiator. Connect the lower radiator hose to the tube extension and secure the tube extension to the frame. Connect the upper radiator hose to the radiator.
3. Fill and bleed the cooling system. Operate the engine until it reaches normal operating temperature; check the coolant level and check the system for leaks.

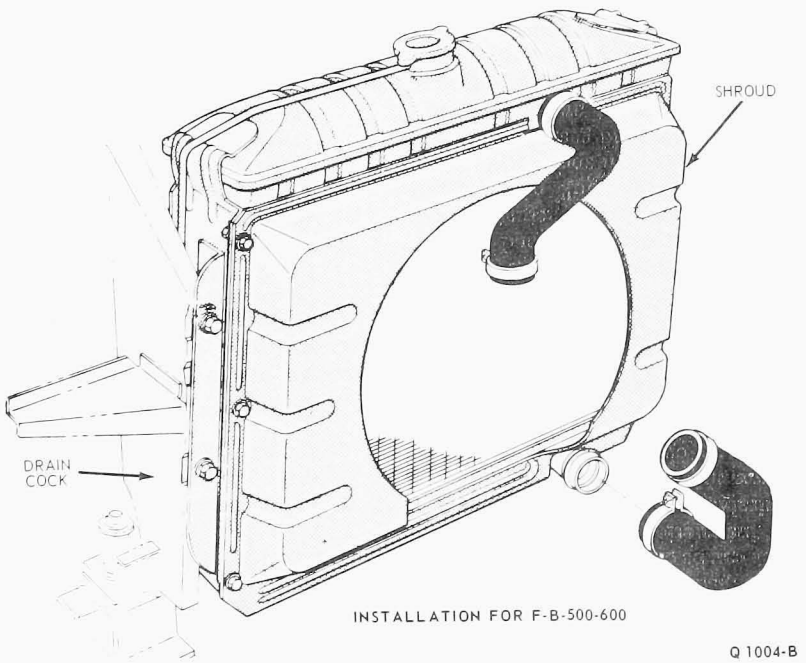

FIG. 6 Radiator Installation—B-F-500-600 Series—Typical

F-100-350 SERIES (WITH 302, 360, 390 8-CYLINDER GAS ENGINES)

Removal

The F-100-350 Series Radiator installations are typical of those shown in Figure 5.

1. Drain the cooling system. Disconnect the upper and lower radiator hoses at the radiator.

On a truck with an automatic

transmission, disconnect the transmission oil cooler line at the radiator.

2. If equipped with a fan shroud, loosen the alternator adjusting arm bolts and loosen the fan belt. Remove the cooling fan retaining bolts and remove the fan assembly.
3. Remove the radiator retaining bolts and remove the radiator and fan shroud, if so equipped.

Installation

1. If a new radiator is to be installed, transfer all the fittings and fan shroud (if so equipped) to the new radiator. **Apply water-resistant sealer to the threads of the draincock.**
2. Position the radiator (and shroud) in the chassis and install the retaining bolts. Connect the radiator upper and lower hoses to the radiator.

If equipped with an automatic transmission, connect the oil cooler line to the radiator.

3. If equipped with a fan shroud, install the cooling fan assembly and adjust the fan belt to specifications.
4. Fill and bleed the cooling system. Operate the engine until it reaches normal operating temperature; check the coolant level and check the system for leaks.

B-F-500-750 SERIES (WITH 330, 361, 391 8-CYLINDER GAS ENGINES)

Removal

The B-and F-Series radiator installation is typical of that shown in Fig. 6.

1. Drain the cooling system. Disconnect the upper and lower radiator hoses at the radiator.

On a truck with a Transmatic transmission, disconnect the oil cooler lines at the radiator.

On a truck with an air compressor, remove the compressor belt.

2. Loosen the alternator adjusting bracket bolts. Remove the fan assembly retaining bolts and remove the fan, spacer, pulley, and fan belt.
3. Remove the radiator retaining bolts and remove the radiator and shroud.

Installation

1. If a new radiator is to be installed, transfer the drain cock and fan shroud to the new radiator. **Apply water-resistant sealer to the threads of the draincock.**
2. Position the radiator and shroud in the chassis and install the retaining bolts. Connect the radiator hoses. Install the fan, spacer, pulley and fan belt. Adjust the drive belt tension to specifications.

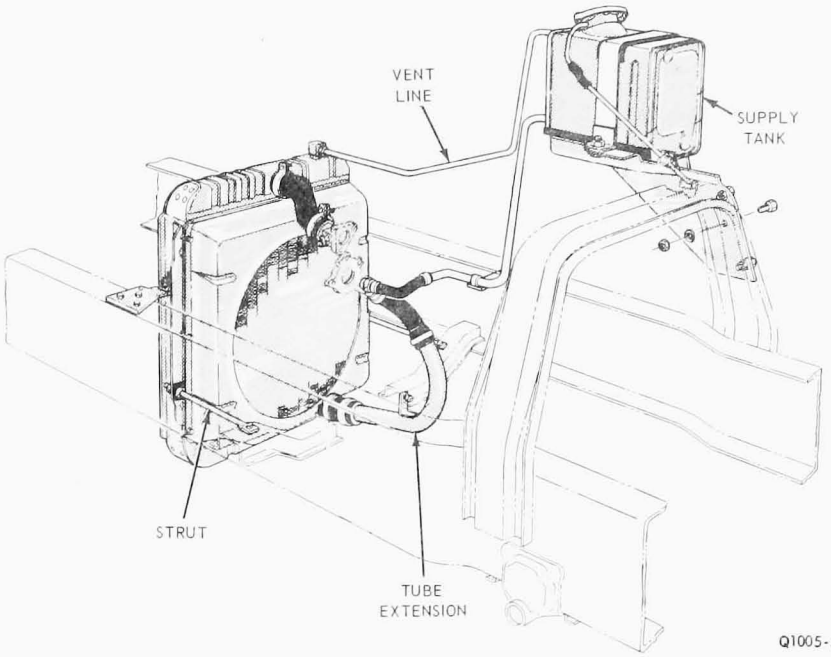

FIG. 7 Radiator Installation—C-500-600 Series—Typical

On a truck with a Transmatic transmission, connect the oil cooler lines.

On a truck with an air compressor, install the air compressor belt and adjust the belt tension to specification.

3. Fill and bleed the cooling system. Operate the engine until it reaches normal operating temperatures and check the coolant level. Check for leaks.

On a truck with a Transmatic transmission, check the Transmatic transmission oil cooler lines for leakage. Check the fluid level.

C-500-800 SERIES (WITH 330, 361, 391 8-CYLINDER GAS ENGINES)

Removal

The C-500-800 Series radiator installation is typical of that shown in Figure 7.

1. Drain the cooling system. Disconnect the upper and lower radiator hoses at the radiator. Disconnect the radiator vent line at the radiator.

On a truck with a Transmatic transmission, disconnect the transmission oil cooler inlet and outlet lines and clamps from the radiator.

On a truck with an air compressor, remove the compressor belt.

2. Remove the tachometer cable clamps from the left side of the radiator. Disconnect the accelerator rod assembly at the cross-shaft and carburetor and remove the rod.
3. Disconnect the supply tank hose clamps from the fan shroud, if so equipped.
4. Remove the bolts securing the fan shroud to the radiator and lay the shroud over the fan. Remove the fan assembly from the crankshaft damper and remove the fan and shroud. Remove the radiator retaining bolts and insulators from top brackets and nuts and insulators from bottom support rods. Remove the radiator.

Installation

1. If a new radiator is to be installed, transfer all fittings to the new radiator. **Apply water-resistant sealer to the threads of the draincock.**
2. Position the radiator in the chassis and install the retaining insulators, nuts and bolts. Place the fan shroud and fan assembly in the chassis and install the fan assembly to the crankshaft damper. Install the fan belt and adjust the belt tension to specifications. Position the fan shroud to the radiator and install the retaining bolts.
3. Connect the upper and lower radiator hoses. Connect the radiator vent line at the radiator. Connect the accelerator rod assembly to the carburetor and cross-shaft. Position

the tachometer cable to the radiator and install the retaining clamps.

On a truck with a Transmatic transmission, connect the transmission oil cooler lines.

On a truck with an air compressor, install the compressor belt and adjust the belt tension to specifications.

4. Position the supply tank hose to the shroud and install the hose clamps, if so equipped.
5. Fill and bleed the cooling system. Operate the engine until it reaches normal operating temperature and check the coolant level. Check for leaks.

On a truck with a Transmatic transmission, check the oil cooler lines for leakage. Check the fluid level.

C-SERIES (WITH 401, 477, 534 8 CYLINDER GAS ENGINES)

Removal

The C-Series radiator installation is typical of that shown in Figure 7.

1. Drain the cooling system. Remove the fan and lower it into the shroud.
2. Remove the heater hose to radiator bracket retaining bolt and remove the bracket and hose from the right side of the radiator.
3. Remove the controls and brackets from the radiator.
4. Remove the draincock.
5. Disconnect the shutterstat to air cylinder line at the top of the radiator. Disconnect the shutter assembly from the radiator and remove the shutter, air cylinder, and air line as an assembly.
6. Remove the radiator left support strap bolt and nut at the radiator and loosen the nut and bolt at the frame and move the support strap out of the way.
7. Remove the radiator right support strap bolt and nut at the frame and loosen the bolt at the radiator and move the strap out of the way.
8. Remove the radiator mounting bolts and remove the radiator, hoses, fan, and shroud.

Installation

1. If a new radiator is to be installed, transfer the hoses, draincock and shroud to the new radiator. **Apply water-resistant sealer to the threads of the draincock.**
2. Place the fan in the shroud and position the shroud and radiator assembly in the chassis.
3. Install the shutter assembly. Connect the shutterstat to air cylinder line.
4. Install and tighten the radiator right and left support strap bolts.
5. Install the fan. Install the draincock and the accelerator cable and clamp bracket. Install the heater hose bracket and position the heater hose in the bracket. Connect the radiator hoses.
6. Fill and bleed the cooling system. Operate the engine until it reaches normal operating temperature and check the coolant level. Check for leaks.

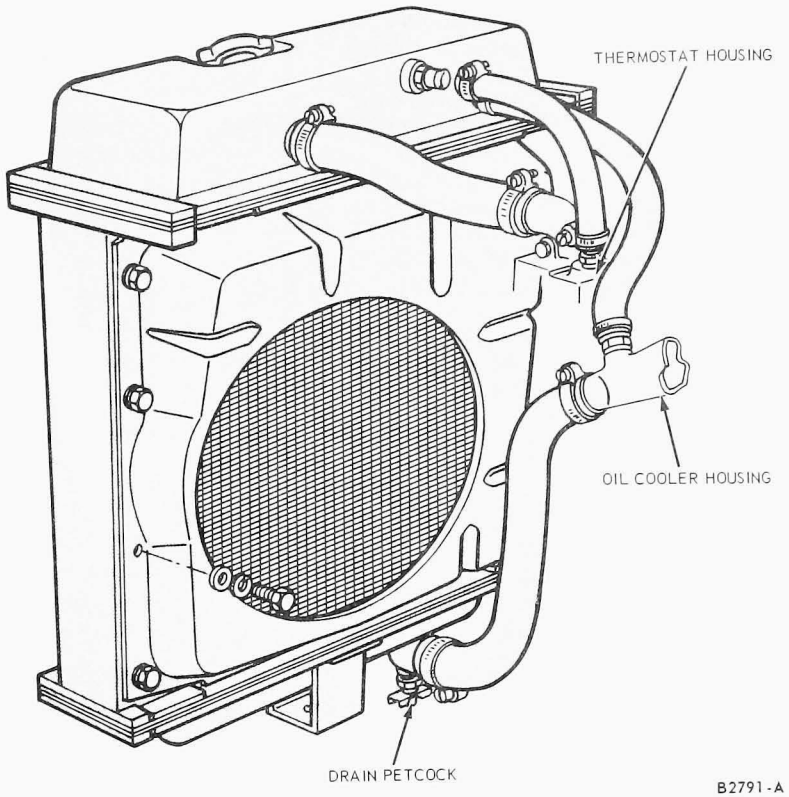

FIG. 8 Radiator Installation—W-Series—Typical

W-SERIES (WITH CUMMINS NH DIESEL ENGINES)

Removal

The W-Series radiator installation is shown in Figure 8.

1. Drain the radiator.
2. Disconnect the radiator hoses.
3. Remove the fan and fan spacer.
4. Remove the bolt, nut, washers and lower insulator from the left and right radiator supports. Remove the nut and washer from the lower radiator support bracket at the frame crossmember.
5. Remove two bolts from the upper header tank. Using two longer bolts, connect a chain to the upper header tank and lift the radiator assembly out with a chain fall. Remove the insulators from the three radiator supports.

Installation

1. If a new radiator is being installed, transfer the radiator shroud, lower support bracket, shutter assembly and drain petcock to the new radiator. Apply water-resistant sealer to the threads of the drain petcock.
2. Position the insulator on the frame crossmember to radiator lower support stud. Tape the insulator to the left and the right support. Lower the radiator into place.
3. Place the large washer and the insulator on the left support bolt and place the bolt through the support and the radiator bracket. Install the washer and nut. Torque the nut to specifications. Follow the same procedure for the right support.
4. Install the lower radiator support retaining washer and nut and tighten the nut until the insulator is compressed to a thickness of 1/4 inch.
5. Install the fan and spacer.
6. Remove the bolts and chain used for removal and install the header tank bolts.
7. Connect the radiator hoses.
8. Fill and bleed the cooling system.
9. Start the engine and check for coolant leaks.

W-SERIES (WITH CUMMINS NTC AND DETROIT DIESEL ENGINES)

Removal

The W-Series radiator installation is shown in Fig. 8.

1. Drain the radiator.
2. Disconnect the radiator hoses.
3. Remove the fan and fan spacer.
4. Remove the bolt, nut, washers and lower insulator from the left and right radiator supports. Remove the nut and washer from the lower radiator support bracket at the frame crossmember.
5. Remove two bolts from the upper header tank. Using two longer bolts, connect a chain to the upper header tank and lift the radiator assembly out with a chain fall. Remove the insulators from the three radiator supports.

Installation

1. If a new radiator is being installed, transfer the radiator shroud, lower support bracket, shutter assembly and drain petcock to the new radiator. **Apply water-resistant sealer to the threads of the drain petcock.**
2. Position the insulator on the frame crossmember to radiator lower support stud. Tape the insulator to the left and right support. Lower the radiator into place.
3. Place the large washer and the insulator on the left support bolt and place the bolt through the support and the radiator bracket. Install the washer and nut. Torque the nut to specifications. Follow the same procedure for the right support.
4. Install the lower radiator support retaining washer and nut and tighten the nut until the insulator is compressed to a thickness of 1/4 inch.
5. Install the fan and spacer.
6. Remove the bolts and chain used for removal and install the header tank bolts.
7. Connect the radiator hoses.
8. Fill and bleed the cooling system.
9. Start the engine and check for coolant leaks.

F-B-SERIES (WITH FORD 8-CYLINDER DIESEL ENGINES)

Removal

The F-and B-Series radiator installation is shown in Figure 9.

1. Drain the cooling system.
2. Disconnect the upper radiator hoses at the radiator.
3. Remove retaining bolts and remove fan.
4. Disconnect the lower radiator hose at the radiator.

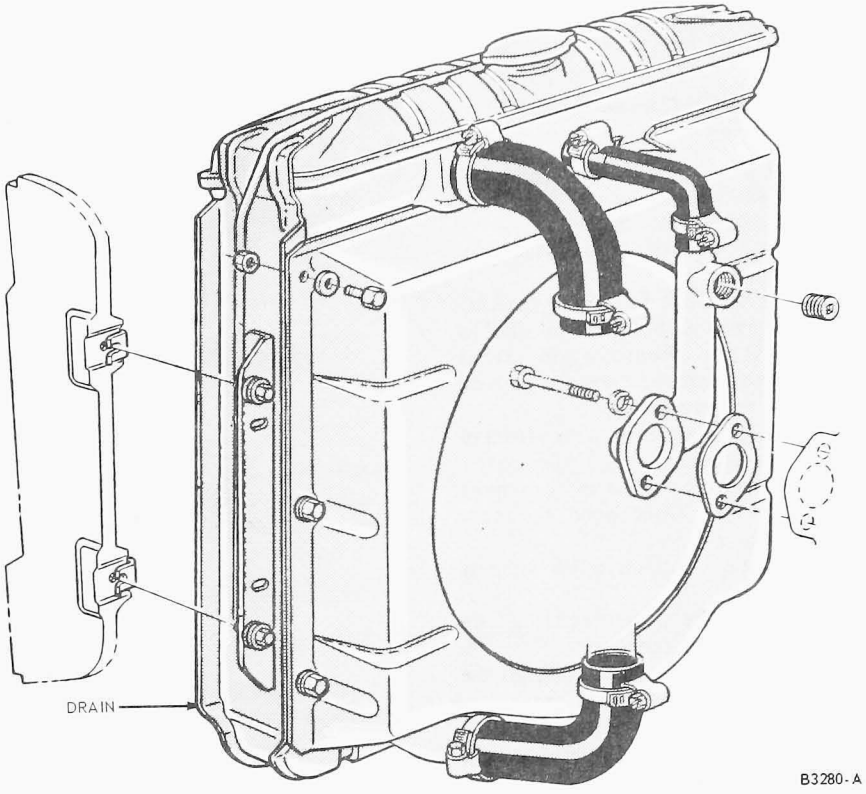

FIG. 9 Radiator Installation—F-B-6000-7000 Series—Typical

5. Remove the bolts securing the radiator to the radiator support and remove the radiator and shroud assembly.
6. Remove the shroud from the radiator.

Installation

1. If a new radiator is to be installed, transfer the drain cock to the new radiator. **Apply water-resistant sealer to the threads of the drain cock.**
2. Install the shroud to the radiator.
3. Position the radiator and shroud to the support and install the retaining bolts.
4. Install the fan.
5. Connect the radiator hoses to the radiator.
6. Fill and bleed the cooling system. Start the engine and check for coolant leaks.

C-SERIES (WITH FORD 8-CYLINDER DIESEL ENGINES)

Removal

The C-Series radiator installation is typical of that shown in Figure 7.

1. Unlock and tilt cab.
2. Drain the cooling system. Disconnect the upper and lower hoses and vent hose at the radiator.
3. Remove bolt and nut retaining accelerator cable bracket to radiator.
4. Remove the cooling fan retaining bolts and remove the fan.
5. Remove nuts, washers and pads retaining the radiator strut to the frame on each side.
6. Remove the two bolts, nuts and pad on each side retaining the radiator support to the frame.
7. Remove the radiator, shroud, supports and braces as an assembly.

Installation

1. If a new radiator is to be installed, transfer the radiator shroud, supports and braces to the new radiator. Transfer the drain cock to the new radiator, **using water-resistant sealer on the threads.**
2. Position the radiator and related parts in the vehicle.
3. Install the radiator support retaining bolts, nuts and pads.
4. Install the radiator strut retaining nuts, washers and pads.
5. Connect the radiator hoses and vent hose.
6. Install the cooling fan and retaining bolts.
7. Install accelerator cable bracket.
8. Fill and bleed the cooling system. Operate the engine until it reaches normal operating temperature;

check the coolant level and check the system for leaks.
9. Lower and lock the cab.

L-SERIES (WITH GAS AND DIESEL ENGINES)

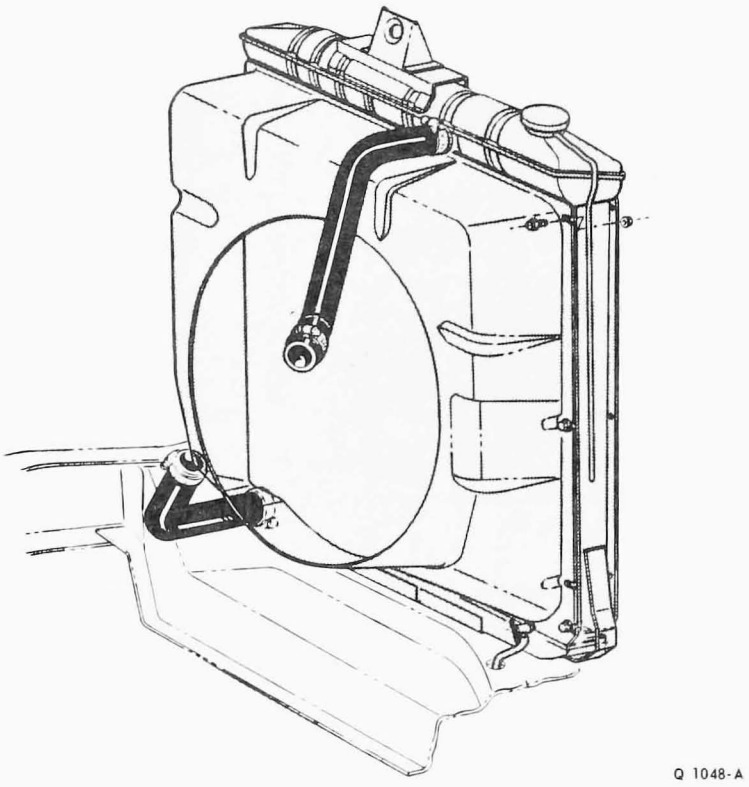
Removal

Radiator installations are typical of those shown in Figs. 10 and 11.

1. Unlock and tilt hood assembly forward.
2. Drain the cooling system. Disconnect all hoses and air lines as necessary. Remove electrical harness clamps and position harness aside, as necessary.
3. Position a support under the front of the hood assembly.
4. Disconnect hood assembly support cables and lower hood assembly onto the support.
5. Disconnect radiator upper support rod.
6. Remove the bolts securing the bottom of the radiator.
7. Using a sling and chain fall, lift the radiator assembly from the truck. Move the radiator forward enough so the shroud clears the fan assembly as the radiator assembly is being removed.
8. Remove the shroud from the radiator.
9. Remove the shutter assembly if so equipped.

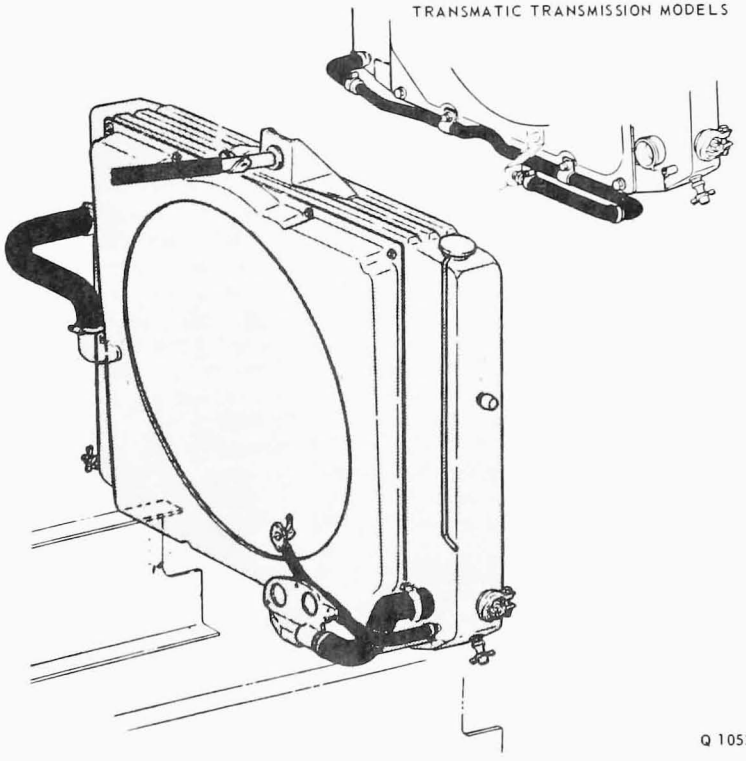
Installation

1. If a new radiator is to be installed, transfer the drain cock and all necessary fittings to the new radiator.
2. Install the shroud to the radiator.
3. Install the shutter assembly if so equipped.
4. Using the proper sling and a chain fall, position the radiator assembly in the truck.
5. Install the lower radiator retaining bolts and upper radiator support rod. Disconnect the sling and chain fall. Be sure to use the correct shoulder bolt for thickness of truck frame.
6. Connect all radiator hoses and air lines as necessary to the radiator. Install electrical harness as necessary.
7. Fill and bleed the cooling system. (Refer to Part 27-02). Operate the engine until it reaches normal operating temperatures; check the coolant level and check the system for leaks.
8. Lower and lock the hood assembly into place.



Q 1048-A

FIG. 10 Radiator Installation—L-Series—Typical



Q 1052-A

FIG. 11 Radiator Installation—L-Series—Typical

RADIATOR SUPPLY TANK

Removal

1. Drain the radiator until the coolant is out of the supply tank. Disconnect the radiator supply tank hose at the supply tank. Disconnect the radiator vent tube at the supply tank, if so equipped.
2. Remove the overflow tube from the supply tank. Remove the supply tank strap or bracket retaining bolt(s) and remove the supply tank.

Installation

1. Position the supply tank in the chassis and install the strap or bracket retaining bolt(s).
2. Connect the radiator hose, overflow tube and vent tube (if so equipped) to the supply tank.
3. Fill and bleed the cooling system. Check for coolant leaks and proper coolant level after the engine reaches normal operating temperatures.

CLEANING AND INSPECTION

COOLING SYSTEM

FORD GASOLINE ENGINES

To remove rust, sludge and other foreign material from the cooling system, use either FoMoCo Regular Cooling System Cleanser or in severe cases use Heavy Duty Cleanser. Removal of such material restores cooling efficiency and avoids overheating.

In severe cases where cleaning solvents will not properly clean the cooling system for efficient operation, it will be necessary to use the pressure flushing method.

Various types of flushing equipment are available. If pressure flushing is used, make sure the cylinder head bolts are properly tightened to prevent possible water leakage into the cylinders.

Always remove the thermostat prior to pressure flushing.

A pulsating or reversed direction of flushing water flow will loosen sediment more quickly than a steady flow in the normal direction of coolant flow.

Do not backflush cooling systems that have a water shut-off valve in the heater system, or damage to the valve can result.

CUMMINS DIESEL ENGINES

To clean the cummins Diesel cooling system, refer to CLEAN COOLING SYSTEM—SPRING AND FALL, in the Cummins Engine Operation and Maintenance Manual.

DETROIT DIESEL ENGINES

To clean the Detroit Diesel cooling system, refer to Cooling System in the applicable Detroit Diesel Highway Maintenance Manual.

FORD V-8 DIESEL ENGINES

Refer to the appropriate Caterpillar Service Manual for instructions on care and cleaning of the cooling systems.

DESCRIPTION AND OPERATION

The automatic shutter controls engine temperature by regulating air flow through the radiator. It provides faster engine warm-up and less variation in operating temperature.

There are three methods of operating the shutters, a thermostatically operated system, an air operated system and a vacuum operated system. The thermostatically controlled system is used on P-5000, W and L-Series trucks. The air operated system is used on other trucks with air brakes. A vacuum operated system is used on other trucks with vacuumboosted hydraulic brakes.

THERMOSTAT OPERATED SYSTEM

The thermostat operated system consists of a shutter control assembly, a shutter control rod or a shutter control cable and a shutter assembly. The shutter control assembly has a power element which works much like a thermostat. When the coolant temperature is below operating temperature, the shutters are closed because of the spring tension at the end of the control rod or cable. As the coolant reaches operating temperature, the power element expands and opens the shutters by working against the spring tension.

AIR OPERATED SYSTEM

The air operated shutter system consists of the shutter assembly, an air cylinder which operates the shutter, and a thermostatically controlled air valve called a shutterstat. With no air pressure on the system, springs in the shutter assembly will hold the shutter blades in the open position. With normal air pressure and the engine below operating temperature, the shutter blades close. As the engine coolant heats to the operating temperature setting of the shutterstat, an air valve in the shutterstat closes, cutting off air to the air cylinder. The air in the air cylinder is then exhausted through the shutterstat and the shutter assembly springs open the shutter blades. Always release the air from the brake system before removing a shutter air line.

VACUUM OPERATED SYSTEM

The vacuum operated shutter system consists of the shutter assembly, a vacuum power cylinder which operates the shutter, and thermostatically controlled vacuum valve called a shutterstat. Operation of this system is the same as for air with the exception that vacuum power is the operating medium.

TESTING

AUTOMATIC SHUTTER TEST
